NEW AMERICAN CYCLOPÆDIA.

COUGH, a violent expiratory movement, excited by some stimulus in the respiratory organs, in which the air is forcibly expelled, carrying with it the mucus or other products accumulated in the air passages. Any irritation from acrid vapors, liquid or solid foreign bodies, too abundant or morbid secretions, or even the action of cold air on the irritated mucous membrane, may produce a cough; the impression is conveyed to the respiratory nervous centre, the medulla oblongata, by the excitor fibres of the par vagum, and the motor impulse is transmitted to the abdominal and other muscles concerned in respiration. Coughing occurs when the source of irritation is in or below the posterior fauces; and sneezing when the irritating cause acts on the nasal mucous membrane. The act of coughing, as defined by physiologists, consists in a long inspiration which fills the lungs; in the closure of the glottis, when the expiratory effort commences; and in the bursting open of the closed glottis by the sudden blast of air forced up from the air passages. The cause of cough may be in the respiratory system, or it may be symptomatic of disease in the digestive and other organs. The cough in laryngitis, croup, and follicülitis arises from irritation in the throat and larynx; in bronchitis, pneumonia, pleurisy, and phthisis, the cause is in the thoracic cavity. Cough may be dry, as in the first stage of pleurisy; or humid, as in certain stages of pneumonia and in advanced consumption; this act may be single, and with distant intervals, or paroxysmal and long continued, as in whooping cough, phthisis, and bronchial catarrh; it may be accompanied by a ringing metallic sound, as in croup and whooping cough, by a hollow resonance or gurgling, as in phthisis with cavities, and by hoarseness, as in laryngeal disease. The character of the cough is characteristic of certain diseases; that of whooping cough and of croup is highly diagnostic; in pleurisy it is dry and hard; in pneumonia, generally humid, with viscid rusty sputa; in consumption it varies with the stage of the affection; but in all these, taken in connection with other symptoms, the cough is a valuable diagnostic sign. Many râles, characteristic of morbid changes, are only or best recognized in the increased respiration after coughing. Cough is frequently accompanied by pain, as in acute pleurisy, pneumonia, and bronchitis; at other times painless, but exhausting, as in the paroxysms of spasmodic coughs. Cough, symptomatic of other than pulmonary disease, is not accompanied by any characteristic phenomena discoverable by auscultation and percussion. The gravity of cough as a symptom depends on the disease in which it occurs; spasmodic coughs generally are not dangerous, except from the liability to rupture of vessels, or other simply mechanical consequences. For the relief of cough the prescriptions are almost innumerable, consisting of compounds of narcotics, antispasmodics, demulcents, expectorants, and alteratives, according to the character of the symptom, the stage of the disease, and the fancy of the physician.

COULOMB, Charles Auguste de, a French philosopher, born at Angoulême, June 14, 1736, died in Paris, Aug. 23, 1806. In early life he was sent to the West Indies as an engineer, and remained there employed in the construction of military works 3 years. In 1773 he presented to the academy a memoir on cohesion, and in 1777 won a prize for improvements in the mariner's compass, and in 1781 another for a theory of machines. As a commissary of the government he won great praise from the inhabitants of Brittany for his defence of their interests against the schemes of certain projectors of canals, and was publicly honored with gifts from them. Leaving Paris at the time of the revolution, he devoted himself to the education of his children and the study of electricity. His published memoirs are upon the statical questions of architecture; the mariner's compass; modes of working under water; simple machines and the stiffness of ropes; windmills; the force of torsion; a stationary compass, in which the needle is hung by floss silk; electricity and magnetism, to which he devoted 9 memoirs; the friction of pivots; the circulation of sap in the poplar; the work of day laborers; and the cohesion of fluids. His fame rests principally on his electrical experiments and calculations. For our knowledge of the forces of electricity we are perhaps as much indebted to him as to any one. In private character he was as estimable as in science he was profound, thorough, and exact.

COUNCIL (Lat. *concilium*, an assembly for consultation), in ecclesiastical history, an assembly of bishops legitimately convoked, to determine questions concerning the faith, rites, and discipline of the church. Councils are either provincial, national, or general, according as they are composed of the prelates of a province, a nation, or of all Christendom; and their jurisdiction is of corresponding extent. The name is also given to the diocesan synod, called by the bishop for the direction of the spiritual affairs of his diocese. Provincial councils are called and presided over by a metropolitan bishop. Their chief design is to make local disciplinary regulations; and though they may discuss questions of faith, their decisions concerning doctrines have no force unless confirmed by the authority of the Catholic church. The general councils of Basel and Trent enjoined that provincial councils should be held once in 3 years, but in recent times the injunction is often disregarded. In France no metropolitan bishop is permitted to call a council unless by express sanction of the civil power. National councils assemble under the presidency of the primate or of a legate of the holy see; they are composed of all the bishops of a kingdom, and are called by princes for the regulation of national ecclesiastical affairs. These councils were frequent in France under the first 2 lines of French kings. More than 100 bishops were assembled by Napoleon in Paris in 1811, to consider the right claimed by him of nominating bishops and cardinals. As, however, they supported the resistance made by Pope Pius VII. to the imperial designs, they were dismissed before they had passed any decision. Among the latest national councils are that of Presburg, in Hungary, in 1822, and that of Würtzburg, in Bavaria, in 1849.—The general councils, called also œcumenical (from Gr. *οικουμενη*, the habitable earth), are summoned by the pope, are composed of all the bishops of Christendom, and are designed to adjudge questions of schism and heresy, belief and discipline, which affect the universal church. Though the first 8 general councils were convoked by the Christian emperors, as Constantine, Theodosius, and Justinian, it was because the church did not then extend beyond the limits of the empire, and therefore the Roman emperor had the same right to call a general council which after the division of the empire belonged to the emperor of Germany, and the kings of France, Spain, and England, to call national councils. It is moreover maintained by Roman Catholic writers that the first general councils were summoned by the emperors at the request or with the consent of the popes. Bishops and their representatives alone have a judicative right in councils, though the privilege has often been extended to abbots and the generals of monastic orders. The lower orders of the clergy and the doctors of the church may be invited, and may participate in the deliberations of the assembly, but have only a consultative voice. The cases in which priests and deacons have voted (St. Athanasius, for instance, having been but a deacon when he took the leading part in the council of Nice) are exceptional, and thought to be founded on the circumstance that they were the representatives of bishops. The pope, in person or by legates, presides over the council and directs its transactions; the emperors who presided in some early eastern councils having done so only in an executive and protective capacity. The decision is usually according to the majority of the votes cast; but in the council of Constance the 4 nations, Italy, France, Germany, and England, each voted separately. General councils do not create new dogmas, but interpret and declare what was originally contained in Scripture and tradition, and according to Roman Catholic belief are under the immediate guidance of the Holy Spirit, and therefore infallible, when they pronounce concerning matters of faith. Their infallibility, however, does not extend to questions of discipline, history, politics, or science, nor even to the grounds of their decision, nor to collateral observations. The disciplinary ordinances are usually termed canons (*canones*), and the decisions concerning doctrines, dogmas (*dogmata*); in the council of Trent, on the contrary, the latter were styled canons, and the former distinguished as *capita* or *decreta*.—The Roman Catholic church recognizes 19 general councils: that of Jerusalem, held by the apostles, about A. D. 50; the 1st of Nice, in Bithynia, convened in 325; the 1st of Constantinople, in 381; the 1st of Ephesus, in 431; that of Chalcedon, in 451; the 2d of Constantinople, in 553; the 3d of Constantinople, in 680; the 2d of Nice, in 787; the 4th of Constantinople, in 869; the 4 councils of Lateran, at Rome, in 1123, 1139, 1179, and 1215; the 1st and 2d of Lyons, in 1245 and 1274; that of Vienne, in Dauphiny, in 1311; that of Constance, in 1414; that of Basel, in 1431 (till its dissolution by the pope); and that of Trent, in 1545. The council of Pisa in 1409, that of Florence in 1439, and the 5th of Lateran in 1512, are also regarded by some as œcumenical. The conference of 192 prelates at Rome in 1854, which proclaimed the dogma of the immaculate conception, was not a council. The Greek church receives as authoritative the decisions of only the first 7 general councils. The Protestant churches generally admit the full authority of none of them, and esteem as œcumenical only the 6 which directly followed the apostolic council of Jerusalem. The synodical assemblies of the Protestant churches, as the councils of La Rochelle and of Dort near the period of the reformation, the general synods of the Evangelical church of Germany, and the convocations of the Anglican church at the present time, cannot in their nature be œcumenical.—The most complete collections of the acts of councils are those of Fathers Labbe and Cossart (Paris, 1671 *et seq.*, 18 vols.), with supplements by St. Baluzius (Paris, 1683 *et seq.*); Hardouin (Paris, 1715, 12 vols.); Coleti (Venice, 1728 *et seq.*, 23 vols.); Mansi (Florence, 1759–'98,

31 vols.); and Disch, the *Concilienlexicon*, embracing all the councils from the first at Jerusalem (Augsburg, 1843–'45, 2 vols.). The best collections of the old French councils are that of Sirmond (Paris, 1629, 3 vols.), with supplements by La Lande (Paris, 1666); of the later French councils, that of Odespun (Paris, 1649); of German councils, that of Schannat, Hartzheim, Scholl, and Neissen (Cologne, 1759–'90, 11 vols.); of German national, provincial, and diocesan councils, from the 4th century to the council of Trent, that of Binterim (Mentz, 1835–'43, 7 vols.); and of Spanish councils, that of Aguirre (Madrid, 1781 *et seq.*). (The history of particular councils is given in special articles under the names of the cities in which they were held.)—In political history, the term council is variously applied to either permanent or extraordinary deliberative assemblies. The political affairs of the cantons of Switzerland are intrusted to councils. Certain courts of justice in France were formerly termed councils.—The Council of Ten was the secret tribunal of the republic of Venice, instituted in 1310, after the conspiracy of Tiepolo, and composed originally of 10 councillors in black, to whom were soon added 6 others in red, and the doge. This council was appointed to guard the security of the state, and to anticipate and punish its secret enemies, and was armed with unlimited power over the life and property of the citizens. All its processes were secret. At first established temporarily, it was prolonged from year to year, was declared perpetual in 1335, and maintained its power till the fall of the republic in 1797.—The Council of the Ancients (*conseil des anciens*), in France, was an assembly instituted by the constitution of the year III. (adopted in the year IV., Sept. 23, 1795), which shared the power with the executive directory, and composed, with the council of 500, the legislative body. It had 250 members, either married or widowers, domiciled at least 15 years in France, and one-third of whom were to be renewed annually. It sat in the Tuileries, in the hall of the convention, and had the power to change the residence of the legislative body. It confirmed or rejected, but could not amend, the measures proposed by the council of 500. It was overthrown on the 18th Brumaire.—The Council of Five Hundred (*conseil des cinq-cents*), instituted at the same time as the council of the ancients, was composed of 500 members, aged at least 30 years, domiciled 10 years in France, and one-third renewed annually. It sat in the hall *du manége*, in the rue de Rivoli, and proposed laws which were read 3 times, at intervals of 10 days. On the 18th Fructidor, year V., 42 of its members were expelled, but it recovered its power with the revival of the Jacobins, and was violently dissolved by Napoleon, on the 18th Brumaire, year VIII. (1799).—The Council of State existed under various names in France from the reign of Philip the Fair. It was composed chiefly of the principal officers of the crown, was dependent upon the will of the king, and followed him in his journeys to advise him on public affairs. The number of councillors of state varied from 15 in 1413, to 30 in 1673. It was limited at the revolution to the king and his ministers, was dissolved in 1792, and was instituted anew in the year VIII., when it was divided into the committees of litigation, the interior, finances, and war. In these committees were elaborated the important laws of the consulate and the empire. This council was modified under the restoration, and now consists of 6 sections. (See Regnault's *Histoire du conseil d'état depuis son origine jusqu'à nos jours*, 1851.)—In England, the Privy Council was formerly the adviser of the king in all weighty matters of state, a function which is now officially discharged by the cabinet. By acts 2, 3, and 4 of William IV., a judicial committee of the privy council was constituted with high powers. All appeals from the prize and admiralty courts, and from courts in the plantations abroad, and any other appeals which by former law or usage had been made to the high court of admiralty in England, and to the lords commissioners in prize cases, are directed to be made to the king in council. These appeals are then referred to the judicial committee of the privy council, which reports on them to his majesty. This committee consists of the chief justice of the king's bench, the master of the rolls, the vice-chancellor of England, and several other persons, *ex officio*, and any two privy councillors may be added by the king.—In Prussia, by a law established March 20, 1807, the council of state (*Staats Rath*) consists of the princes of the royal family who have attained their majority, and of the highest officers of the state who enjoy the special confidence of the king. Its decisions have no validity without the royal sanction.—A Council of War is an assembly of the principal officers in an army or fleet, called by the officer in chief command to deliberate and advise concerning measures to be taken. The council of administration, in the army of the United States, under the congressional act of July 5, 1838, appoints the chaplain, fixes a tariff to the prices of sutlers' goods, and makes appropriations for specific objects from the post and regimental funds.—In some of the United States there are bodies termed councils, which are elected to advise the governor in the executive part of his office, and have power to reject or confirm his nominations to office.

COUNSELLOR, a lawyer whose peculiar function is pleading in public, the same as the English barrister. The duties of a counsellor and attorney at law are usually performed by the same individual in the United States; but in England and in the U. S. supreme court they are distinct, the counsellor being retained for oral pleading and for advice on intricate law points, while the attorney addresses himself to advice on ordinary matters, to the practice of the courts, and to communication with clients.

COUNT (Fr. *comte*; It. *conte*), a title of no-

bility used in most countries of continental Europe, and corresponding with that of earl in Great Britain. It is derived from the Latin *comes*, meaning companion, which, under the republic, designated young Romans of family accompanying a proconsul or proprætor during his governorship or command, in order to acquire a practical knowledge of political and military affairs. Under the empire a number of persons belonging to the household of the court, or to the retinue of the chief of the state, received the title of comes, with some addition designating their function or office. Comites as well as jurisconsulti surrounded the emperor when sitting as judge, to assist him in the hearing of causes, which were thus judged with the same authority as in full senate. This mark of office was first converted into a title of dignity by Constantine the Great. As such it was soon conferred not only on persons of the palace, or companions of the prince, but also on most kinds of higher officers. These dignitaries, according to Eusebius, were divided into 3 classes, of which the first received the distinguishing appellation of illustrious, the second, that of most renowned, and the third, that of most perfect. The senate was composed of the first two. Among the multitude of officers who, at this period of the Roman empire, were dignified by the title of comes, and of whom some served in a civil, some in a legal, and others in a religious capacity, we find comites of the treasury, of sacred expenditures, of the sacred council, of the palace, of the chief physicians, of commerce, of grain, of the domestics, of the horses of the prince or of the stable (*comes stabuli*, the origin of the modern constable), of the houses, of the notaries, of the laws, of the boundaries or marks (the origin of the later margrave and marquis), of the harbor of Rome, of heritages, &c. Most of these titles were imitated, with slight modifications, in the feudal kingdoms which arose on the ruins of the Roman empire. Thus we can easily trace in some of the above mentioned titles the origin of the modern grand almoner, grand master of ceremonies, grand master of the royal household, grand equerry, &c., in which the word grand is used as a substitute for the ancient comes. Under the Franks counts appear as governors of cities or districts, next in rank to the dukes, commanding in time of war, and administering justice in time of peace. Charlemagne divided his whole empire into small districts (*pagi*, Ger. *Gaue*), governed by counts, whose duties are minutely described in the capitularies of the monarch. The Frankish counts had also their deputies or vicars (*missi* or *vicarii*, whence our viscount or *vice-comes*). Under the last of the Carlovingian kings of France the dignity of the counts became hereditary; they even usurped the sovereignty, and their encroachments remained unchecked even after the accession of Hugh Capet, who was himself the son of the count of Paris, and it was not until the lapse of several centuries that their territories became by degrees reunited with the crown. The German term for count, *Graf* (which is variously derived from *grau*, gray or venerable; from γραφω, to write, whence the mediæval Latin word *graffare*, and the French *greffier*; from the ancient Grman *gefera*, companion, and *gerefa*, bailiff or steward, whence the English sheriff) first appears in the Salic law in the form of *grafio*. With the development of the feudal system, as well as of that of imperial dignitaries in Germany, we find there counts palatine (*comes palatii*, *palatinus*, *Pfalzgraf*), presiding over the supreme tribunal; constables, afterward marshals (*Stallgraf*); district counts (*Gaugraf*); counts deputy (*Sendgraf*), controllers of the preceding; margraves (*Markgraf*), intrusted with the defence of the frontiers (*Mark*); landgraves (*Landgraf*), counts of large possessions; burggraves (*Burggraf*), commanders, and afterward owners of a fortified town (*Burg*), &c. With the decline of the imperial power most of these titles became hereditary, as well as the estates or territories with which they were connected, the dignity and possessions of the counts ranking next to those of the dukes in the empire. But there were also counts whose title depended solely on their office, as counts of the wood, of the salt, of the water, of mills, &c. The dignity of count is now merely a hereditary title, mostly attached to the possession of certain estates, and bestowed by the monarch, but including neither sovereignty nor jurisdiction, though connected in some states with the peerage, as was the case for instance under the late constitution of Hungary. In England, where the wife of the earl is still termed countess, the dignity of count was attached by William the Conqueror to the provinces or counties of the realm, and given in fee to his nobles. The German term has been adopted by several nations of Europe, as for instance by the Poles (*hrabia*), Russians (*graf*), and Hungarians (*gróf*).

COUNTERPOINT. See Harmony.

COUNTERSCARP, in fortification, the outer slope or boundary of a ditch. The inner slope is called *escarpe*. The term is applied also to the whole covered way, with its parapet and glacis, as when the enemy is said to be lodged in the counterscarp.

COUNTERSIGN, the signature of a secretary or other public officer to attest that a writing has been signed by a superior. Thus the certificates *recognovit, relegit, et subscripsit* are common on charters granted by kings in the middle ages.—In military affairs, the countersign is a particular word given out by the highest in command, intrusted to those employed on duty in camp and garrison, and exchanged between guards and sentinels.

COUNTY (Fr. *comté*), in Great Britain and some of the British colonies, and in most of the United States of America, a political division nearly corresponding to a province of Prussia or a department of France. It is synonymous with shire, with which designation it is often interchanged in England, but never in Ireland. The division of England into shires or counties,

though popularly attributed to Alfred, was probably of earlier date, since several of them, as Kent, Sussex, and Essex are nearly identical with ancient Saxon kingdoms. There are now 52 counties in England and Wales, 33 in Scotland, and 32 in Ireland. The county is an administrative division, and its principal officers are a lord lieutenant, who has command of the militia; a *custos rotulorum*, or keeper of the rolls or archives; a sheriff, a receiver-general of taxes, a coroner, justices of the peace, an under-sheriff, and a clerk of the peace. The assize court, county court, and hundred courts, are the chief judicial tribunals. There are in England 3 counties palatine, Chester, Lancaster, and Durham, the earl of each of which had all the *jura regalia*, or rights of sovereignty, in his shire. The first two of these have been long annexed to the crown, and Durham, previously governed by its bishop, was annexed in 1836. The United States are divided into counties, with the exception of South Carolina (divided into districts) and Louisiana (divided into parishes). In each county there are county officers who superintend its financial affairs, a county court of inferior jurisdiction, and stated sessions of the supreme court of the state.

COUP (French), a blow, is used in various connections to denote a sudden, decisive action, as *coup de main*, in military language, a prompt, unexpected attack; *coup d'œil*, in the same, a rapid conception of the advantages and disadvantages of position and arrangement in a battle; *coup de grâce*, a killing stroke, finishing the torments of the victim; *coup de théâtre*, a sudden change in the action; *coup de soleil*, a stroke of the sun; *coup d'état*, a sudden, arbitrary, and forcible measure in politics, used mostly for the violent overthrow of a constitution.

COUPON (Fr. *couper*, to cut), an interest certificate attached to the bottom of bonds on which the interest is payable at particular periods. There are as many of these certificates as there are payments to be made, and at each payment one of them is cut off and delivered to the payer.

COURAYER, Pierre François le, a Roman Catholic ecclesiastic, born in Vernon, Normandy, 1681, died in England, 1776. He had taken refuge in England (1728) in consequence of a "Defence of English Ordinations," which he had published (1723) as a result of the convictions to which he was brought by a correspondence with Archbishop Wake. The correspondence took place while Courayer was canon of St. Geneviève, and professor of theology and philosophy. The university of Oxford conferred on him the title of doctor of laws, and Queen Caroline settled a pension of £200 on him for a French translation of Father Paul's "History of the Council of Trent." He also translated Sleidan's "History of the Reformation," and wrote several theological works. He entertained many religious opinions contrary to the doctrines and practices of the church of Rome, but declared himself, two years before his death, still a member of her communion. He was buried in the cloisters of Westminster abbey.

COURCELLES, Thomas de, a French theologian, born in 1400, died in Paris, Oct. 23, 1469. He was educated at the university of Paris, of which institution he became one of the brightest ornaments. In 1430 he was chosen rector of that university, and in 1431 was made canon of Amiens, Laon, and Thérouanne. He took a prominent part in the trial and condemnation of Joan of Arc, but was not present at her execution. In the process of her rehabilitation in 1456 he made no excuse for his conduct in this affair.

COURIER DE MÉRÉ, Paul Louis, a French scholar and publicist, born in Paris, Jan. 4, 1772, murdered near Veretz (Indre-et-Loire), April 10, 1825. Having received an excellent education, he took, while in the army of Italy, every opportunity of visiting libraries and works of art, and denounced in his private correspondence the spoliation of the latter by the French soldiery. Returning to France in 1800, he attracted the attention of Hellenists by the publication of his remarks upon Schweighäuser's edition of Athenæus. In 1806 he was again with the army, stationed in dangerous and isolated parts of Calabria, and afterward at Naples and Portici, where he occupied his leisure hours in translating Xenophon's treatise on cavalry, and on equitation. Censured for lingering in Rome and Florence instead of attending to his duties, he threw up his commission, but rejoined the army just before the battle of Wagram, after which, however, he left it entirely. While in Florence, he had discovered in the Laurentian library an unedited manuscript of Longus, "Daphnis and Chloe," which he published in Greek and French in 1810. Having, however, in copying the manuscript, accidentally blotted it with ink, he was accused of doing so purposely, and ultimately expelled from Tuscany, while the 27 remaining copies of the 52 he had printed were seized by the Tuscan government. This proceeding was probably prompted by Courier's castigation of the Florentine library authorities in a spirited letter addressed to M. Rénouard, and prefixed to his Longus. On his final return to France in 1814, he married, at the age of 42, a young lady of 18, a daughter of his friend, the Hellenist Clavier. The restoration gave him opportunities of trying his strength in politics. He denounced the follies of the new administration in numerous pamphlets, which produced a strong impression upon the public mind, but involved Courier in troubles with the government, and he was arrested on several occasions. His most effective pamphlet, *Pamphlet des pamphlets*, appeared in 1824, and was called by his biographer, Armand Carrel, "the last note of the expiring swan," for during the spring of the following year he was found shot near his country seat. Five years later it was ascertained that he had been murdered by his gamekeeper, Frémont, who had died of apoplexy, but no clue was discovered to the motive which

prompted him to the deed. Courier's pamphlets are masterpieces of style. They have been published, together with his translations from the Greek and other works, in Paris, 1834, in 4 vols., and reprinted by Didot in 1 vol. The best edition of his translation of Longus is that of 1825.

COURLAND, or KURLAND, one of the Baltic provinces of Russia in Europe, bounded N. by the gulf of Riga and Livonia, E. by the government of Vitepsk, S. by that of Kovno, and W. by the Baltic sea; area, 10,608 sq. m.; pop. in 1851, 539,270. The face of the country is level, but interspersed with some hills, the highest of which has an elevation of 700 feet. The province contains a great many forests, especially of pine and fir, and there are said to be no less than 300 lakes and ponds, beside a large number of small streams and brooks, and several rivers. Among the larger rivers are the Düna, Aa, and Windau. The soil is not rich, but when properly tilled is productive. The principal products are wheat, rye, barley, oats, peas, beans, hemp, flax, and linseed. Clay, iron, lime, and gypsum are found, and are wrought to some extent. The manufactures are unimportant. The province is formed of the old duchies of Courland and Semigallia, united with the ancient bishopric of Pilten, and the district of Polangen, which once formed part of the duchy of Lithuania. It is divided into 5 arrondissements, each of which is subdivided into 2 captaincies. It has 2 shipping ports, Libau and Windau. Capital, Mitau. The predominant religion is Protestantism, and the ecclesiastical affairs are conducted by the consistory of Mitau. There are about 15,000 members of the Greek church and 45,000 Roman Catholics, who together possess but 19 churches, and are subject respectively to the bishops of Samogitia and Pskof. There are also many Jews, Poles, Russians, and various residents of other nations, among whom are the Krewincks, a race of Finnish descent. The nobility and the city population, and the higher classes generally, are of German descent, while the peasantry and the lower classes are chiefly of Lettish origin. Courland was ruled for a long time by sovereign dukes, as a dependency of the Polish crown. By the marriage in 1710 of Duke Frederic William with the princess Anna of Russia, the influence of that empire became predominant in Courland. It was strengthened in the following year, when after the duke's death Anna was appointed regent, under the protection of Peter the Great. After Anna's accession to the Russian throne in 1730, her uncle Ferdinand officiated as duke of Courland until his death in 1737. Subsequently the duchy was ruled by Anna's favorite, the adventurer Biron, who died in 1772, and bequeathed it to his eldest son Peter. The latter, failing to give satisfaction to the country, was obliged to cede Courland to Catharine II. in 1795. Since that time it has formed part of Russia, though retaining some ancient privileges. The civil governor of Courland is now (1859) M. de Brevern, who resides in Mitau, while the general direction of affairs devolves upon the governor-general of the Baltic provinces, in 1859 Prince Italiski.

COURT (Lat. *curia*, the senate house), in the early middle ages, the feudal lord and his family, with their companions and servants—all the persons, collectively regarded, who occupied the various departments of a feudal castle. After the rise of the modern monarchies the name was given by preëminence to the family of the sovereign and their attendants, the residents in the royal palace. Pomp and obeisance had waited on the ancient Roman and oriental masters of empires, and when Charlemagne founded the empire of the West he adopted the titles and ceremonial which were in use in the palace of the emperors of Constantinople. The marriage of the emperor Otho II. with the Byzantine princess Theophania, also contributed to spread in Europe the usages of the imperial court of the Orient. The *cours plenières*, which followed the establishment of royal over feudal supremacy, were assemblages of all the nobility of the kingdom around the monarch. Charles V. in vain sought to introduce permanently into the German courts the severe and stately manners of the Spanish; and the Spanish reverences and bending of the knee were soon succeeded by the fashion of merely bowing the head. The French court, as organized by Francis I., became a model of politeness and taste to all Europe. Affirming that "a court without ladies is a year without spring, and a spring without roses," this monarch introduced more of elegance and freedom into society, and substituted the spirit of gallantry for that of courtesy. A distinction was made between the severe manners of the palace and the freer etiquette allowed in the field and in travelling. The French court obtained its highest prestige for wit and grace under Louis XIV. In England, the courts of Elizabeth and Queen Anne have been most illustrious for the learned and witty men that attended them, and that of Charles II. was most famous for its gayety. The court *ton* is any peculiarity of manner imitated from the personal habit of the sovereign. The Spanish language was spoken in the German imperial court till about the end of the 16th century, when it was succeeded by the Italian. Near the end of the 17th century the French had become the usual court language in all the countries on the continent, but about the beginning of the present century was partially succeeded by the German in most of the German courts. —The right of admittance or presentation at court belonged originally only to the nobility. It was extended also to the higher clergy, and to some distinguished persons, as great artists or scholars, whose accomplishments were regarded as giving them personal nobility. The reign of Frederic the Great and the period of the French revolution relaxed the conditions of presentation, though Napoleon in his new imperial court revived all the dignities and strict-

ness of ceremonial which had existed under the old *régime*. The precedence of diplomatic agents and others at court is determined partly by the relative rank of states, important republics, as the United States and Switzerland, receiving the same honors as kingdoms; and partly by the degree of relationship to the sovereign, since nearly all the European dynasties are united to each other by family ties.

COURT, in law, an institution having a two-fold object, viz.: the conservation of public order by the suppression of violence and crime, and the adjudication of disputes on civil matters between the individuals constituting a community. The first of these is most prominent in a rude state of society; the latter, in an advanced stage of civilization. In the earlier and ruder condition, the laws have principal reference to protection from personal violence, and the judicial function is chiefly exercised in rendering speedy justice to the offenders. Another peculiar distinction is also observable in the administration of laws at the different periods above referred to. In the earlier, it is vested in the executive, which at that time is usually the sole constituent of the government, and this continues to be the characteristic of every nation whose advance beyond semi-barbarism is arrested, or whenever from a state of partial civilization it returns again to its original rude condition. Such was the primitive administration of laws in the states of Greece; the king or chief of a people was not merely a military leader, but also a judge; and this is now the case in oriental autocracies, with only the modification that where the territorial jurisdiction is large, as in Turkey or Persia, the laws are administered by deputies, but who, in like manner as the sovereign of a small state, each within his respective district, perform the functions of executive and judicial officers. A third circumstance may be observed, viz.: that in the earlier period a large discretion is exercised in judicial proceedings. The laws being few, cases will occur that are not provided for; and again, personal security being the chief object had in view, summary justice is naturally preferred to the more tardy form of proceeding which would be involved by a regard to the rules of evidence which in a more advanced stage of society are deemed essential; indeed, these rules are an after growth, and require a long experience and an intellectual habit to develop.—The Roman consuls were at first executive and judicial magistrates. The progress of the people in civilization was indicated by their demand of some check upon the arbitrary judgment of the consuls in their judicial capacity, which led to the compilation of the laws of the 12 tables; a still further advance was shown in the separation of the judicial from the consular office, and the appointment of the prætor. But although the Roman mind was eminently legal, it did not during the existence of the republic attain to a clear idea of the importance of a supervisory power for the correction of the errors of inferior tribunals. The assemblies of the people, both the *centuriata* and *tributa*, had indeed a judicial power, but it was exercised in the hearing of cases in the first instance, and those chiefly of persons charged with capital offences. But in civil causes (*judicia privata*) there was not properly an appeal from the judgment of the prætor, or of the judges (or more properly juries) appointed by him. The nearest approach to it was the power exercised by the prætor in certain cases of setting aside the sentence of the *judices* for fraud, and so the assistance of the tribunes was sometimes invoked against the corrupt conduct of the prætor himself. Under the imperial government an appeal was allowed from all inferior judges to the emperor, which was in fact usually heard by a court composed of the chief officers of state and distinguished jurists. Even this court was not, however, strictly subject to the rules which are in modern times deemed essential to an appellate court. It not only decided cases brought before it by appeal from the final judgments of inferior tribunals, but would take original jurisdiction in many cases while they were pending before a subordinate court, and not merely made decisions (*decreta*) in such cases, but also gave opinions (*rescripta*) to magistrates or private persons upon questions proposed by them. —In the constitution of judicial tribunals under modern European governments there has been a great advance beyond the Roman in all of the particulars which we have named above as appertaining to the administration of law. The separation of the judicial from executive functions has become gradually recognized as a political principle. In England it was asserted at an early period for the protection of personal freedom against royal power, but it was imperfectly carried into effect until within the last 2 centuries, when the tenure of judicial office was made independent of the pleasure of the king. The clause of Magna Charta, *Communia placita non sequentur curiam nostram, sed teneantur in aliquo loco*, though seemingly intended for the mere convenience of suitors, by prescribing a certain place for the trial of their causes, instead of compelling them to travel about with their witnesses wherever the *aula regis* held by the king in person might be, in reality had the effect of breaking up that court, and ultimately of establishing the several courts of common pleas, king's bench, and exchequer, presided over by justices appointed for that purpose. The king's bench alone, which retained jurisdiction of criminal cases, continued for some time afterward to be migratory, whence the common form of process returnable to that court was *ubicunque fuerimus;* and this prevailed after the court became fixed like the others at Westminster, and its itinerancy was but a mere legal fiction. But the judges of all these courts were appointed by the king, and could be removed by him at will; and this power of removal continued until by statute 13 William III.

(1701) it was enacted that the commissions of the judges should be *quamdiu se bene gesserint*, instead of *durante bene placito* as formerly, and that they should be removable only upon an address of both houses of parliament. The chancellor alone, who presides over the department of equity, is subject to removal at the pleasure of the king, and his office is held entirely by a political tenure. There are 4 courts of original and general jurisdiction, viz.: the king's bench, common pleas, exchequer, and chancery. These may be considered the outgrowth of the common law, though according to a popular mode of expression chancery is distinguished from the other three, as if not of common law origin, but the equity administered in that court was chiefly indigenous. The ecclesiastical and admiralty courts, on the other hand, derive their mode of administering law from a foreign source, though the limit of their respective jurisdictions is prescribed by acts of parliament, or by long usage, which is supposed to be founded upon statute. The court of king's bench, in the distribution of judicial powers upon the breaking up of the ancient aula regis, retained, as we have mentioned, jurisdiction of criminal cases; but to this was added all that class of cases which, though in reality civil actions between private citizens, yet, as they involved an allegation of force (as in actions for trespass, where the act complained of was alleged to have been done *vi et armis*), were deemed *quasi* criminal. But notwithstanding this narrow limit of its cognizance of civil cases, it remained in one sense the highest court in the realm. It has always been the representative of the king's prerogative, has exercised authority over all other common law courts so far as to restrain them within their proper jurisdiction by writ of prohibition, and has always exercised summary power, in all cases not otherwise provided for, to compel inferior courts and magistrates to do their duty. By a fiction of law it has also acquired jurisdiction over all civil cases except actions relating to real estate, and may in one form of action, viz., ejectment, even try titles to land; which fiction consists of an allegation in pleading that the defendant has been arrested upon process of that court for a trespass, whereupon the plaintiff complains against him for another and the real cause of action. The court of common pleas had originally exclusive jurisdiction of all merely civil actions not involving any criminal offence, and it still retains sole cognizance of actions relating to realty except ejectment, which, as before mentioned, may be also brought in the king's bench. The business of the court of exchequer was originally the collection of debts due to the crown, the proceeding for which was by bill, somewhat in the nature of a bill in chancery, whence this was called the equity side of the court; but jurisdiction was obtained of all personal actions by a fiction, viz., an allegation that the king's debtor hath suffered an injury whereby he is less able to pay his debt, *quo minus sufficiens existit*, whereupon he was allowed to implead in this court the person charged with the wrong. This was called the common law side of the court. The old forms of process and proceeding peculiar to these courts have been recently abrogated, but the jurisdiction acquired by them remains. Substantially the same process and mode of pleading is now used in the three courts, by stat. 2 William IV., c. 39 (1832), and other acts, the provisions of all which are included in the more general revision by stat. 15 and 16 Vic., c. 76 (1852), and 17 and 18 Vic., c. 125 (1854). As to the nature and extent of the jurisdiction of the court of chancery, see article Chancery. From all these courts an appeal lies to the house of lords. There are, however, some intermediate appeals. From each of the three courts it has been long the practice to adjourn cases of great importance, before judgment, to the court of exchequer chamber, consisting of the barons of the exchequer, the chancellor, lord treasurer, and justices of the king's bench and common pleas. There is also an appeal, in certain cases after final judgment, to the same court (in which cases on appeal the judges of the court from which the appeal is taken do not sit), and from that court an appeal lies to the house of lords; and so in all other cases which are not reviewed in the court of exchequer chamber. Cases in chancery are usually heard in the first instance before the master of the rolls or a vice-chancellor, from whom an appeal lies to the chancellor (with whom two lords justices have been recently associated for the hearing of appeals), and from them to the house of lords. A writ of error, it is said, may also issue from the king's bench to the common pleas, but it seems to have been rarely used. The trial of all common law causes in the first instance is before itinerant or circuit judges, one of whom must be a justice of one of the superior courts of Westminster, which judges are sent annually into every county of the kingdom for the trial of civil and criminal cases which are to be brought before a jury. They were first appointed in the reign of Henry II., and were then called justices in eyre (*justiciarii in itinere*), but are now designated as justices of assize and nisi prius. Their commission also authorizes them to try all criminal cases, which part of their duties is expressed by the old law phrases of oyer and terminer (to hear and determine), and general gaol delivery; the former relating to cases upon which an indictment is found by a grand jury at the same circuit, the latter to indictments previously found upon which there had been an arrest and imprisonment of the parties indicted. The commissions of assize and nisi prius relate to civil causes. Assize in the old English law was the name applied to the trial of issues relating to the freehold, by a species of jury called recognitors, who were allowed to decide upon their own personal knowledge without the examination of witnesses; in modern law the term designates issues in actions relating to real estate. *Nisi prius* is a phrase in the writ issued to the sheriff for the summoning of a jury, by which he is

commanded to bring them before the court at Westminster at a certain day in term, unless before that time the justices of assize should come into his county; and as the justices accordingly come, the sheriff returns the writ at the court of assizes.—In France, the administration of justice, which originally belonged to and was exercised by the suzerains or feudal lords in person, was, by a process similar to what took place in England, vested in certain officers appointed for that purpose, who at first were considered as the mere deputies of the suzerain, but were afterward recognized as having independent official functions. One peculiarity prevailed in all the seigniories, viz., that whether the seigneur or his deputy, or the latter judicial magistrate (under the name of *bailli*), presided, it was necessary for the adjudication of any question to call together the principal vassals, who in fact constituted a court, although at first they were spoken of rather as advisers of the seigneur than as judges; but afterward, when the baillies held the courts, they were obliged to submit every case to the judgment of the assembled vassals, who then began to be called peers. These courts decided all questions between the vassals themselves or between vassal and seigneur, except that in the latter class of cases such questions were excluded as involved a contest between the seigneur and the vassals generally, which questions were brought before the suzerain or superior lord of whom the seigneur held. In other cases, where the seigneur refused to decide,or interfered with the proper administration of right, an appeal was often made to the superior lord; and so also for an unjust judgment, probably, however, only in a case of flagrant violation of right. The former appeal was called *en défaut de droit*, the latter *en faux jugement*. In either case, however, the ground of the appeal was some misconduct of the seigneur or his representative, and not strictly for a review of a case fairly conducted. But instead of such appeal,the vassal who thought himself aggrieved by the judgment of his seigneur could challenge him to combat, first renouncing fealty to him. From these seigneurial courts subsequently grew up the *parlements*. There was at first but one, viz., the court of the king. The first Capetian sovereigns created 4 grand *bailliages* to hear appeals from all judgments rendered in the courts of the seigneurs, and to judge in the first instance where there was a conflict of jurisdiction; but these tribunals were not uniformly acknowledged, and the vassals still resorted to the court of the king. In consequence of the accumulation of business, and the great expense of attending upon that court at various places, Philip the Fair, by an edict in 1302, made the sitting of the court permanent at Paris. He also established a *parlement* for Languedoc. The *exchiquier* of Normandy was fixed at Rouen permanently by Louis XII., and was entitled by Francils I. a *cour de parlement*. Others were afterward established, and these courts continued to be the appellate tribunals until the revolution. Henry II. established presidences (*présidiaux*) in the principal cities, reserving to the *parlements* only the more considerable causes and inspection of the inferior courts. The *parlements*, which originally consisted of the peers of France, were finally composed of lawyers appointed by the king. They were abolished in 1790, and in their palce, so far as respected appellate jurisdiction, was substituted the court of cassation. This court was composed of 52 judges, who, by the *charte constitutionelle* of 1814, received their appointment from the king, but were not removable. Tribunals of appeal were created a few years after the establishment of the court of cassation (1802), which after the restoration were called *cours royales*, and under Napoleon III. *cours impériales*. The exact limits of the jurisdiction of the latter courts and of the court of cassation are not defined with much precision. The court of cassation, which now consists of 45 judges, 3 vice-presidents, and a president, is divided into 3 chambers, viz.: a chamber of requests, a chamber of civil, and a chamber of criminal cassation. Demands in cassation (applications for reversal of judgment) are first heard by the chamber of requests, which either rejects them or sends them to one of the other chambers to be adjudicated. The appeal to the *cours impériales* is directly from the tribunals of first instance, *tribunaux civil d'arrondissement*, which are the same that were established in 1790 under the name of *tribunaux de district*.—This brief review of the courts of the two countries of Europe most celebrated for their jurisprudence, will sufficiently illustrate how far they fulfil the conditions of a sound administration of justice in two particulars, viz.: freedom from executive control, and a due regard to the correction of errors by a review of the first judgment in an appellate court. There are, however, other important considerations to which we may properly advert. Judges should be independent not only of executive influence, but also of all personal responsibility to litigant parties. There is a singular feature in the French law which indicates either a low state of judicial integrity or an entire oversight of an important principle of jurisprudence. By a proceeding called *prise à partie*, which has been recognized from an early period, a judge is liable to be sued by the party against whom he has rendered judgment. The old rule was, that he could be made responsible only when the judgment was without excuse (*doit être affectée et inexcusable*); by an ordinance of Francis I. (1540) a judge was not liable except for fraud or extortion (*s'il n'y a dol, fraude, ou concussion*). Still he was subject to a suit for damages, and several old writers commented strongly upon the peril to society in subjecting judges to such a liability, especially for judgments in criminal proceedings. But notwithstanding these remonstrances, the proceeding has always been and still is allowed. Merlin mentions a number of cases in which the

judge would be held responsible, among which are: 1, arresting a person without proper complaint, except in case of flagrant crime (*hors le cas de flagrant délit*); 2, arrest without proof, or for an offence which was not punishable by imprisonment; 3, where the judge has exceeded his power by taking cognizance of a matter without having jurisdiction; 4, evoking a case from an inferior tribunal under pretext of an appeal, and then not disposing of it. The provisions of the code of civil procedure lack precision. The cases of *prise à partie* are: 1, for fraud or extortion, in the language of the ordinance of Francis I.; 2, where it is expressly prescribed by law; 3, where the law has declared judges liable for damages; 4, if the judge has denied justice. (*Code de procédure*, § 505.) The English law, on the contrary, affords an ample protection to judges. The rule is, that no private suit will lie against judges of a court of general jurisdiction, either for error of judgment or even for misconduct in their judicial functions; and the same protection is extended to judges of courts of inferior jurisdiction when acting within the limit of their authority. For official corruption, or other criminal conduct, a judge may be impeached and removed from office, and is also liable to be proceeded against by indictment; but no other redress is allowed to a suitor who may have sustained injury by such misconduct. If, however, a judge having a limited jurisdiction should exceed it, that is to say, should undertake to act in a matter not within his jurisdiction, then he becomes liable to a suit for damages, even if it was a mere mistake of judgment. Thus the court of Marshalsea, which had jurisdiction only of cases in which one of the parties was of the king's household, or trespasses committed within the verge of the court, having given judgment for a debt of which they had no cognizance and imprisoned the debtor, the judges and even the ministerial officers were all held liable to damages, the proceeding being *coram non judice* (case of the Marshalsea, 10 Coke's Rep. 68); but in the same case it was said that where a court has jurisdiction of a cause and proceeds erroneously, an action will not lie against the party who sues or against the officer or minister of the court. A single exception may possibly exist in respect to the immunity given to judges of courts of general jurisdiction, viz.: where they act extra-judicially, as in the case mentioned by Hawkins: "If a judge will so far forget the honor and dignity of his post as to turn solicitor in a cause in which he is to judge, and privately and extra-judicially tamper with witnesses or labor jurymen, he hath no reason to complain if he be dealt with according to the capacity to which he so basely degrades himself." The rule, however, as above stated, has been sustained by the most eminent English judges. (See Groenvelt *vs.* Burwell, 1 Salk. 396; Miller *vs.* Seare, 2 Bla. Rep. 1141; and Mostyn *vs.* Fabrigas, Cowp. 161.) In the case last cited, a governor of Minorca was sued in England for a false imprisonment alleged to have been committed by him while governor. Lord Mansfield said, if it had been done judicially it would have been a complete bar to the action, but as governor he had no such exemption, and he mentioned several cases of naval officers in the British service against whom actions had been brought and damages recovered for acts done by them officially in foreign parts. There was an interesting discussion of this subject in the courts of the state of New York in the case of Yates *vs.* Lansing, which was an action against the chancellor, and the English doctrine was fully considered and sustained. (5 Johnson's Rep. 282; 9 id. 375.) The same exemption from private suit on account of judicial acts which is given to judges is also extended to jurors, who, by the English and American law, are judges of facts.—Another important requisite for the proper administration of law is certainty in the rules of decision. A discretionary power has been shown by common experience to be unsafe, however specious the idea may be of determining each case upon its own equity. A general rule, known beforehand and rigidly adhered to, is preferable to an oscillating and precarious judgment, although cases of individual hardship will occur in the application of such rules. There will, however, be cases not foreseen or provided for; in respect to these, shall the judges exercise a discretionary power, or should there be a judicatory to take special cognizance of them, or lastly, should legislative action be invoked? The Roman prætors intermingled equitable relief with their judicial decisions. In the English judicial system the court of chancery has had an exclusive but still limited authority to give relief in certain cases upon principles of equity differing from the strict rules of law. Yet even in the administration of equity that court soon became bound by its own precedents, from which it was not at liberty to depart, and the chancery law of England is at this day as well settled as the law administered in the other courts. Bacon proposed in his aphorisms *De Justitia Universali*, that there should be what he calls prætorian courts, having power as well of relieving from the rigor of the law as of supplying the defects of law, that is, prescribing the rule in cases not otherwise provided for (*De Aug.*, lib. 8, c. iii., aph. 31). The English courts all decide according to precedents, or if no former decision can be found, then by analogy to what has been decided in similar cases, or upon some general principle which has been recognized; and in cases entirely new have sometimes sought aid from the Roman law. There is one class of cases, however, in which positive law alone is acted upon, and that is in respect to crimes and their punishment. Crimes must be defined by law, which may be either by statute or by ancient prescription, but courts have no power to declare new crimes; and so in regard to punishment, courts can enforce no other penalty than what has been previously fixed by law. The *parlements* of France were

in like manner bound by the *arrets réglementaires*, rules of decision established in former cases. On the reorganization of the courts in 1790 an attempt was made to abrogate all power of deciding from analogy, or even by a resort to general principles of jurisprudence; and all cases not provided for by express law were to be referred to the national assembly for the purpose of having such law enacted as would be applicable to the particular case. This crude experiment was so unsatisfactory that in the *Code Napoléon* it was thought necessary not only to restore to the courts the power of deciding upon general principles and analogy, but it was even made penal to do otherwise (*Code Napoléon*, art. 4).—The courts in the United States have a general correspondence with the English judicial system. The modifications are chiefly these: 1. In the federal courts, as well as the courts of most of the states, the equity powers of the English chancery have been vested in the other courts, though the English system of equity is still substantially administered. Hence our courts may be said to have an equity and a common law side. 2. Local circuit judges have been generally substituted in place of the itinerant or nisi prius judges of England. The judges of the supreme court of the United States have each a certain territorial limit in which they respectively act as circuit judges. In the state of New York 8 judicial districts have been established, and the supreme court is constituted of 4 judges in each district, who in their respective districts are independent, resembling in that respect the French *parlements*, but in another respect they are all members of one tribunal, as each judge is competent to act in any district, either by voluntary arrangement with the judges of such district, or by direction of the governor. But the prevailing system in most of the states is the appointment of local judges for the trial of causes who are unconnected with an appellate tribunal. 3. In many of the states the judges are elected like other public officers by popular vote.

COURT DE GÉBELIN, Antoine, a French author, born in Nîmes in 1725, died in Paris, May 10, 1784. He was the son of Antoine Court, and early in life officiated for a short time as a preacher. Subsequently he devoted himself to the study of ancient mythology, in which, as in many other branches of knowledge, he was deeply learned. He established himself in Paris in 1763, and between 1775 and 1784 published the 9 vols. of his great work entitled *Le monde primitif*, in which he traces the history of the moral and intellectual world. The work was the fruit of 20 years' severe labor, and was to have embraced several additional volumes, the preparation of which was prevented by the author's death. He sympathized deeply with the American struggle for independence, and cooperated with Franklin and others in the publication of a work advocating the American cause, entitled *Affaires de l'Angleterre et de l'Amérique*. He was the author of a defence of animal magnetism, and of a variety of works, historical, philosophical, and political.

COURT MARTIAL, a tribunal authorized in the United States by the articles of war, and in England by the mutiny act, for the trial of all persons in the army or navy charged with military offences. According to articles 64 *et seq.* of the congressional act of May 29, 1830, any general officer commanding an army, or colonel commanding a separate department, may appoint a general court martial, except when such officer or colonel shall be the accuser, in which case the court shall be appointed by the president of the United States. A general court martial may consist of any number of commissioned officers from 5 to 13, but shall not be less than 13 when that number can be convened without manifest injury to the service. The commanding officer decides as to the number. Such a court has no jurisdiction over any citizen not employed in military service. The sentence of the court shall not be carried into execution until the whole proceedings have been laid before the officer commanding the troops for the time being. In time of peace, no sentence extending to loss of life, or the dismission of a commissioned officer, and either in peace or war, no sentence against a general officer, shall be carried into execution until confirmed by the president of the United States, to whom, through the secretary of war, the whole proceedings shall be transmitted. Every officer commanding a regiment or corps may appoint a court martial consisting of 3 commissioned officers, to judge offences not capital committed in his own regiment or corps. Such a court martial may be appointed also by the officers commanding garrisons, forts, or barracks. But in neither of the cases has it power to try a commissioned officer, or to inflict penalties beyond certain limitations.

COURT OF LOVE (Fr. *cour d'amour*), in mediæval France, a tribunal composed of ladies illustrious for their birth and talent, whose jurisdiction, recognized only by courtesy and opinion, extended over all questions of gallantry. Such courts existed from the 12th to the 14th century, while the romantic notions of love which characterized the ages of chivalry were predominant. The decisions were made according to a code of 31 articles, which have been preserved in a MS. entitled *De Arte Amatoria et Reprobatione Amoris*, written by André, royal chaplain of France, about 1170. Some of the troubadours were often present to celebrate the proceedings in verse, and the songs of these minstrels were not unfrequently reviewed and judged by the tribunals. Among the ladies who presided were the countess De Die, called the Sappho of the middle ages, and Laura de Sade, celebrated by Petrarch. King René of Anjou attempted in vain to revive the courts of love, and the last imitation of them was held at Rueil at the instance of Cardinal Richelieu, to judge a question of gallantry which had been raised in the hôtel de Rambouillet.

COURTEN, William, an English manufacturer and merchant, born in London in 1572, died there in May, 1636. His father had been a tailor at Menin, in the Netherlands, and escaping with difficulty from the persecution of the duke of Alva, had arrived in London in 1568. The Courten family were engaged in the manufacture of French hoods, then much in fashion, and at the death of the parents about the end of Elizabeth's reign, the sons were opulent merchants in silks and linens. In 1631 William and Peter received the honor of knighthood, when their returns amounted to £150,000 a year. They made large loans both to James I. and Charles I., and had a claim upon the crown of over £200,000. The first severe loss which Sir William Courten suffered was occasioned by Lord Carlisle, who seized as a grant from the crown the island of Barbados, on which the former had built a factory, as a place discovered and protected by himself. His agents at Amboyna, in the Spice islands, were subsequently murdered by the Dutch, and all his property there destroyed. Engaging in the Chinese trade, the loss of two richly laden ships completed his disasters, reducing him to poverty a short time before his death.—William, last male descendant of the Courten family of merchants, born in London in 1642, died at Kensington Gravelpits in 1702. Educated by his wealthy relatives, he began early to travel and to display a love of natural history. He resided and studied at Montpellier, and when of age returned to England to claim the shattered fortune of his family. After a long lawsuit he changed his name for that of William Charleton, and retired to Montpellier, where he lived for 25 years, enjoying the society of Tournefort and Sir Hans Sloane. He returned again to England, and took chambers in the Temple, where he lived during the last 14 years of his life. Locke was one of his intimate friends. He made a large collection of coins, precious stones, and various curiosities in medallic and antiquarian history; and his industry is proved by his catalogue, which embraces 46 volumes. His antiquarian collection, which he left to Sir Hans Sloane, now belongs to the British museum.

COURTOIS, Jacques, or Cortesi, Jacopo. See Borgognone.

COURTRAI, or Courtray (Flemish, *Kortryk*), a town, capital of the arrondissement of the same name, in the province of West Flanders, Belgium, 75 m. from Brussels; pop. in 1857 of the arrondissement 136,505, and of the town 22,216. It is situated on the river Lys, an affluent of the Scheldt. It is handsomely built; contains several fine edifices, including a town hall, 2 fine churches, an exchange, a college, and 2 orphan asylums. In one of the churches (Notre Dame) is Vandyke's great painting, the "Elevation of the Cross." The inhabitants are actively engaged in the linen manufacture. The fine linens known under the name of Courtrai cloth are made in the neighboring districts. The flax culture in the neighborhood of Courtrai has a world-wide reputation. There are also large bleaching grounds and manufactories of thread lace and silk lace. The town was the Cortoriacum (afterward written Curtricum) of the Romans. It was near Courtrai that the famous battle of spurs was fought (1302), so called from the number of spurs collected from the French knights who fell in it. The name of Courtrai frequently occurs in the history of the Netherlands; it was often taken by the French, who finally destroyed its fortifications in 1744.

COUSIN, Jean, a French painter, sculptor, and engraver, born about 1501 at Soucy, near Sens, died about 1589. His paintings on glass, many of which were executed in churches, royal palaces, and princely residences, are still highly valued, some having been preserved, as the "Legend of St. Eutopius" and the "Sibyl consulted by Augustus," in the cathedral church of Sens. A large specimen of his oil paintings on canvas, the "Last Judgment," is in the Louvre. He is the author of two treatises, *Le livre de perspective*, and *La vraie science de la portraiture*. He is reckoned by many as the founder of the French school of painting.

COUSIN, Victor, a French philosopher, born in Paris, Nov. 28, 1792. His father was a clockmaker, a faithful disciple of Jean Jacques Rousseau, and a revolutionist. The first public school that he attended was the Charlemagne lyceum, in which he was noted for his severe studies and gained the highest prizes. Especially interested in rhetoric, the imitative arts, and music, he determined to make literature his vocation, and as a distinguished student his name was in 1810 placed first on the list of pupils admitted into the newly organized normal school. He became assistant Greek professor in this school in 1812, master of the conferences in 1814, held at the same time a chair in the Napoleon lyceum (Bourbon college), and during the Hundred Days was enrolled in the *élite* corps of royal volunteers. Meantime his attention had been diverted from belles-lettres to philosophy. The attractive lectures of Laromiguière, one of the society of Auteuil, and the most graceful of the followers of Condillac, first interested him in sensationalism or ideology, the reigning philosophy of the 18th century. The spirit of the age was, however, set against this system; Napoleon had denied to it the power of showing any thing grand in human nature or destiny; and the reaction against it was animated by the religious enthusiasm of the Catholics De Maistre and De Bonald, by the loyal and poetical sentimentalism of Châteaubriand, and was spread through literature and art by Mme. De Staël and Quatremère de Quincy. In philosophy Laromiguière indicated a point of departure from it by admitting the active and voluntary force of sentiment in alliance with the passive and receptive faculties of the understanding; but the first who openly revolted from the authority of Condillac was Royer-Collard, who developed in France the spiritual theories of the Scotch school, and of whom Cousin was the favorite pupil. When at

the close of 1815 the former was raised to civil office under the restoration, Cousin became his successor as deputy professor of philosophy in the Sorbonne, and for 5 years he lectured both at the university and the normal school. From the speculations of Maine de Biran concerning the will, he derived the germs of his ideas of personality, causality, and liberty; and his earliest courses followed the system of Reid, and were devoted in general to an exposition of ideal truth. The vacations of 1817 and 1818 he spent in Germany, acquainting himself with the literature and thinkers of that country; and the metaphysics of Kant tinged the lectures delivered after his return. In 1820, in consequence of the royalist reaction in the state, his views of free agency were thought to have a political intent, and his course was indefinitely suspended. Two years later the normal school was closed by a royal ordinance. The leisure thus afforded he occupied in prosecuting his editions of Proclus (6 vols. Paris, 1820–'27), of Descartes (11 vols. Paris, 1826), and his translation of Plato, with summaries, on which he employed, like Raphael, the labor of his pupils subject to his own revision (13 vols. Paris, 1825–'40). He also took charge of the education of a son of Marshal Lannes, and in 1824 visited Germany with his pupil. He was arrested at Dresden, on suspicion of being an accomplice of the carbonari, was taken to Berlin, where he suffered a captivity of 6 months, and was visited in prison by Hegel, whose philosophy was then predominant in Germany. He also became intimately acquainted with Schleiermacher and Schelling. Returning to Paris, he published in 1826 the first series of his *Fragments philosophiques* (followed by a series of *Nouveaux fragments* in 1828), favored the increasing liberal party, and in 1827, when the Villèle ministry was supplanted by that of Martignac, he was restored to the chair of philosophy in the Sorbonne, with Guizot and Villemain for colleagues. The successful triumvirate at once attracted audiences to the university unexampled in numbers and enthusiasm since the time of Abelard. Stenographic reports of their lectures were also distributed throughout France. Cousin had already unfurled the banner of eclecticism in the preface to his *Fragments philosophiques*, and he now fully developed the theory that 4 pure systems of philosophy have alternately prevailed, each of which is the perversion of a truth, and that the human mind can cease to revolve in the circles of past error only by uniting the elements of truth contained in each system, so as to form a composite philosophy superior to all systems. He found in the East, in Greece, in mediæval scholasticism, and in all modern speculations, only different phases of sensualism, idealism, scepticism, and mysticism. With equal delight and skill in metaphysical exercises, his forte lay in developing a system from its central principle till it took in the universe in its consequences. His eloquence was at once impetuous and grave, his style and splendid language recalled the stateliness of the old French classics, and his enthusiastic discourse ran within an hour over nature, humanity, Deity, philosophy, history, religion, destiny, industry, society, and great men. The students, accustomed to the calm dissertations of the sensationalists, followed with admiration his adventurous flight through all truths and all errors. The speculations and strange technology of the German philosophical development from Kant to Hegel he was the first to unfold to French audiences, giving popular expression to theories of the absolute. His lectures derived additional interest from the political temper of the time, a liberal audience gladly discovering political allusions in the words of a liberal professor. It was at this period that Cousin enjoyed his highest reputation as an expositor of philosophical ideas. At the revolution of 1830 he took no part in the 3 days' struggle, but immediately after dedicated a volume of Plato to the memory of one of his pupils who had fallen in the fight. Under the new *régime* he might have entered with Guizot, Villemain, and Thiers into the chamber of deputies, but chose to adhere to his philosophical studies, declaring politics to be only an episode in his career. He soon became counsellor of state, member of the royal council of public instruction, officer of the legion of honor, titular professor in the Sorbonne, member of the French academy to succeed Baron Fourier (1830), and of the academy of moral and political sciences at its foundation (1832), director of the reëstablished normal school, and peer of France. As the recognized head, too, of what was termed the official philosophy, he was exposed to constant and contradictory attacks from the clergy and the opposition. He reorganized the system of primary instruction in France, arranged the admirable plan of studies which is still retained in the normal school, and visited Prussia (1833) and Holland (1837) to observe the institutions of public instruction in those countries, concerning which he published full and valuable reports, which were translated into English by Mrs. Austin. He urged that national instruction should be associated with religion and founded on the Christian principle, and maintained that education which is not specially religious is likely to be hurtful rather than beneficial, since it opens new avenues to immoral tendencies without providing efficient checks. This view he illustrated with great learning on the subject in speeches delivered in the chamber of peers. In 1840 he entered as minister of public instruction into the cabinet of Thiers, which lasted but 8 months, in which time he made the programme of philosophical studies in the lyceums, and suggested other improvements, of which he gave an apologetic account in the *Revue des deux mondes* for Feb. 1841. In 1844 he gained his greatest parliamentary distinction by his speech in the chamber of peers in defence of the university and of philosophy, which was published in a volume. Though surprised by the revolution of 1848, he gave it his aid, and began the series of publications undertaken by

the institute at the request of Gen. Cavaignac to confirm the *morale* of the people. He issued a beautiful popular edition of Rousseau's *Profession de foi du vicaire Savoyard*, and in short treatises entitled *Philosophie populaire* and *Justice et charité* combated the doctrines of socialism. Since 1849 he has disappeared from public life.—After 1830, when he ceased for the most part to deliver academic lectures, he became one of the writers for the *Journal des savants*, and for the *Revue des deux mondes*, in which many of the articles composing his volumes of *Fragments de philosophie ancienne*, *Fragments de philosophie scholastique*, *Fragments de philosophie moderne*, *Fragments littéraires*, and other collections, first appeared. His other chief philosophical publications are, an introduction to the history of philosophy (1828), a history of philosophy in the 18th century (1829), a translation of Tennemann's history of philosophy (1829), a treatise on the metaphysics of Aristotle (1838), lectures on the philosophy of Kant (1841), lectures on moral philosophy delivered between 1816 and 1820 (1840–'41), a work entitled *Du vrai, du beau, et du bien* (1853), and editions of the *Sic et Non* of Abelard (1836), of the works of Maine de Biran (1834–'41), of the *Pensées* of Pascal (1842), of the works of André (1843), and of the works of Abelard (1849). All of his editions are remarkable for the thoroughness with which the text has been revised from original MSS., and many of them contain documents from old libraries which had not before been discovered. One of the most acceptable fruits of his research is the recovery of the original MS. of the "Thoughts" of Pascal, where, through the erasures, corrections, interpolations, and reconstructions, the reader is introduced into the laboratory of Pascal's eloquence. The biography of Jacqueline Pascal (1844) is founded chiefly on inedited or unknown documents.—As a philosopher, the plan of Cousin has been to publish systems, and from systems to deduce philosophy. The most characteristic feature at once of his method and his results is his theory of the reason. The reason, in his view, has spontaneous consciousness of absolute truths, and furnishes to the mind ideas of infinite objects which could not be formed by any power of abstraction from observation of particular, finite, and contingent things. To know these ideas is the aim of philosophy, and the reason would be perfectly cognizant of them if it were not misled by the senses, passions, and imagination. There is something true in every system of philosophy, since error can never reach to utter extravagance. This element of truth exists in the reason, and may be found by impartial examination of the consciousness, and of the history of humanity. From the drama of changing systems, which is the history of philosophy, let the truth which constitutes the positive side of every system be taken, exclusive of whatever constitutes its negative and false side. The ideas thus obtained will furnish a spectacle of the universal consciousness, and will be the sum of eclectic philosophy. If the question be raised concerning the authority of the reason, and the certainty that its ideas are universal truths, Cousin, in order to answer, passes from psychology to ontology. Human reason, he says, is not a part of the human personality, but is in its nature impersonal, absolute, and infallible, the logos of Pythagoras and Plato, a mediator between God and man. Its qualities are those precisely opposed to individuality, namely, universality and necessity, and its spontaneous ideas rightly understood are revelations of a world unknown to man. This theory finds its completion in theodicy. As every phenomenon implies a substance, as our faculties, volitions, and sensations imply a person to whom they belong, so absolute truths have their last foundation in an absolute being, and ideal truth, beauty, and goodness are not mere abstractions, but are the attributes of the infinite Being whom we call God. Eclecticism is rightly regarded by Cousin in his work on the true, the beautiful, and the good, the last expression of his opinions, less as a doctrine than as a banner, as less an instrument of philosophy than of morality, as less effective to discover truth than to advance virtue. He has suppressed the words in his *Fragments philosophiques* in which he affirmed the system of Schelling to be true, though Schelling had then declared for "either Bruno or absolute unity;" and with less reliance upon metaphysics, he maintains the spirit and tendency of all his speculations to promote that philosophy which began with Socrates and Plato; which the gospel spread through the world; which Descartes subordinated to the severe forms of modern genius, and which always contributes to subject the senses to the mind, and to elevate and ennoble man.—His latest publications have been histories and biographies illustrating French society in the 17th century. In the stately proprieties and careful speaking and writing which distinguished the period of the Fronde and of the hôtel de Rambouillet he finds admirable examples of conversation, festive entertainments, heroic actions, noble sentiments, and great characters. His series of studies on Madame de Longueville (1853), Madame de Sablé (1854), Madame de Chevreuse and Madame de Hautefort (1856), and that entitled *La société Française au XVII^e^ siècle, d'après le Grand Cyrus de Mlle. de Scudéry* (1858), have the same elevation of thought and sentiment, the same poetical and eloquent style, which mark his discussions and histories of philosophy; and like many of these, also, they abound in dates, citations, documents, and annotations.—The principal American editions of Cousin's philosophical writings are the "Introduction to the History of Philosophy," translated by Henning Gottfried Linberg (Boston, 1832); the "Elements of Psychology," from his lectures, by C. S. Henry (Hartford, 1834; last edition, New York, 1856); selections from his works, with introductory and critical notices, in Ripley's "Philosophical Miscellanies" (Boston, 1838);

his "Course of Modern Philosophy," by O. W. Wight (New York, 1855); and his "Lectures on the True, the Beautiful, and the Good," also by O. W. Wight (New York, 1857).

COUSTOU, the name of 3 French sculptors. I. Nicolas, born in 1658, died in 1733. His masterpiece is the "Descent from the Cross," in the church of Notre Dame, at Paris. II. Guillaume, brother of the preceding, born in 1678, died in 1746. Among his best works is a marble statue of Cardinal Dubois. III. Guillaume, son of the foregoing, born in 1716, died in 1777. His fame rests upon the statues of Mars and Venus, which he executed for Frederic the Great.

COUTELLE, Jean Marie Joseph, a French engineer, born at Mans in 1748, died there, March 20, 1835. Franklin's invention of lightning rods made a great impression upon his mind, and the first instrument of the kind in Mans was to be seen in his house. He devoted himself particularly to the improvement of air balloons. For some time he commanded the aërostatic corps which accompanied the army of the Sambre-et-Meuse, and afterward he followed Bonaparte to Egypt, but his balloons were destroyed at the battle of Aboukir. He was promoted to the rank of colonel, but in 1816 he was removed from active service. The celebrated work on Egypt, published by the French government, contains 2 essays of his, one on the topography of Mt. Sinai, and the other on the meteorology of Cairo.

COUTHON, Georges, a French revolutionist, a lawyer by profession, born near Clermont in 1756, guillotined July 28, 1794. He was a member of the constituent assembly, and afterward of the convention, moved the resolution which decreed the arrest of the Girondists, and officiated as commissioner in Lyons, where he ordered the most beautiful buildings which had belonged to the royalists to be destroyed. He was noted for his violence, and for his fanatical devotion to Robespierre, whose fate he shared.

COUTTS, Angela Georgiana Burdett, an English philanthropist, born April 25, 1814. She is the youngest daughter of the late Sir Francis Burdett, and on her mother's side a granddaughter of the wealthy banker, Thomas Coutts. Her early prospects were not brilliant, as her father's family was a large one, and her grandfather's fortune, which had been left to his widow (the actress, Miss Mellon, whom he married late in life), had apparently been diverted into another channel by the marriage of the latter with the duke of St. Albans. The duchess, however, having no children of her own, determined that the fortune of her first husband should revert to his family, and made Miss Angela Burdett her heiress, on condition that she should assume the name of Coutts. In 1837 Miss Burdett Coutts succeeded to this vast property, estimated at between 2 and 3 millions sterling, and since that time has dispensed large sums annually—amounting probably to her entire income —in various charities. One of the most important of these was the building and endowment, in 1847, of a church, with a parsonage and schools attached, the site of which in Rochester row, Westminster, one of the neglected parts of London, was selected by the late Dr. Blomfield, bishop of London, who also acted on other occasions as her agent or almoner. The outlay for this work amounted to £30,000. She has also endowed a bishopric in Adelaide, South Australia; and in 1858 appropriated £15,000 for a similar purpose in British Columbia.

COUTURE, Thomas, a French painter, born at Senlis, Dec. 21, 1815, was a pupil of Gros and of Paul Delaroche. His principal work, the "Romans of the Decadence," first exhibited at Paris in 1847, is now in the gallery of the Luxembourg palace. His pictures are remarkable for vitality and broad effects of color. In 1855 he exhibited "The Falconer," and has since been employed upon 3 new pictures, called "Volunteer Enrolments," the "Return of the Crimean Troops," and "Baptism of the Imperial Prince."

COVENANTERS. See Cameronians.

COVENTRY, a city, municipal and parliamentary borough of Warwickshire, England, on the Sherbourne, 10 m. N. N. E. of Warwick, and 94 m. by the London and northwestern railway N. N. W. of London; pop. in 1851, 36,812. In conjunction with some adjacent villages it was formed into a separate county by Henry VI., but an act of parliament in 1842 united it with Warwickshire. Its name, a corruption of *Conventre*, or "convent town," came from a Benedictine priory, founded in 1044 by Leofric, lord of Mercia, and his lady Godiva, of which the cellar, 225 feet long by 15 feet wide, still exists. The ancient part of the city has narrow, ill paved, and crooked streets, built up with antiquated houses; the modern part is laid out with great neatness, filled with handsome and comfortable dwellings, and supplied with gas and water. There are 3 ancient and 3 modern churches, and several chapels. Among the educational establishments is a free school, founded in the time of Henry VIII. by John Hales, having an income of £950 per annum, 2 fellowships at Oxford, 1 at Cambridge, and 6 exhibitions at either university. There are 6 endowed and various private schools, a government school of design, mechanics' institute, 2 libraries, a convent of the sisters of charity, hospital, dispensary, savings bank, theatre, county hall, drapers' hall, barracks, and a great number of charitable foundations. St. Mary's hall, a venerable building of the 15th century, with a principal room 63 feet long, 30 feet wide, and 34 feet high, has a curiously carved roof, and a large painted window. It was built for the Trinity guild, but is now used for public celebrations, meetings, &c. The manufactures of Coventry were celebrated at a very early date. At the commencement of the 15th century an active trade was carried on here in woollen cloths, caps, and

bonnets, and there were flourishing manufactures of caps, woollens, and broadcloth. Afterward blue thread, called "Coventry true blue," and still later tammies, camlets, shalloons, and callimancoes, were staple manufactures; but the articles now most largely made are silks, ribbons, fringes, and especially watches, the last more extensively than even at London. The ribbon manufacture employs about 6,000 persons in the city, and 14,000 more in the neighboring villages. Coventry was anciently defended by walls and towers, but only a small portion of the former and 3 of the latter remain; the rest were destroyed by Charles II. on account of the favor shown by the citizens to the parliamentarians. Two parliaments were held here, one by Henry IV. in 1404, the other by Henry VI. in 1459. The people were noted for their love of all kinds of shows, pageants, and processions, descriptions of which have furnished matter for several curious and interesting works. The religious dramas called mysteries were performed here with peculiar magnificence as early as 1416, and not unfrequently in the presence of royalty. A procession still annually takes place here, commemorative of the legend of the countess Godiva, who is said to have obtained from her husband Leofric the repeal of certain heavy imposts under which the citizens complained, on condition that she should ride naked through the streets of Coventry at noonday. She ordered the people to keep within doors and close their shutters, and, veiled only by her long flowing hair, she mounted her palfrey and rode through the town, unseen except by an inquisitive tailor, immortalized under the sobriquet of "peeping Tom," whose curiosity was punished by instant blindness. This story, on which Alfred Tennyson has founded a beautiful poem, was first recorded by Matthew of Westminster, who wrote in 1307, 250 years after its supposed occurrence. The procession, as now held during the great fair, which takes place in Trinity week, dates from 1677, and before the passage of the municipal reform act was solemnly attended by the city authorities. The principal characters are St. George of England on his charger, and the lady Godiva, who is represented by a female with flowing hair, clad in a close-fitting flesh-colored garment, and riding a gray horse. Strong efforts have been made to suppress this exhibition, but without success.—Coventry is connected with the grand trunk navigation by the Coventry and Oxford canal, and with the chief emporiums of the kingdom by the great northwestern and 2 branch railways. It sends 2 members to parliament. The meaning of the phrase "sending to Coventry" is variously given. Some suppose it to have originated with military men, who were formerly regarded with disfavor by the inhabitants.

COVERDALE, Miles, bishop of Exeter in the reign of Edward VI., born in Yorkshire in 1487, was educated in the house of Augustine friars at Cambridge. Attached in his early years to the religion in which he had been educated, he was ordained a priest of the order of St. Augustine in 1514, at Norwich. Afterward changing his opinions, he dedicated himself solely to the service of the reformation, and was among the first at Cambridge to renounce allegiance to the church of Rome. Finding residence in England unsafe, he went abroad, and assisted Tyndale in his translation of the Bible. In 1535 he published a translation of his own, with a dedication to King Henry VIII.; of this edition no perfect copy is now known to exist. The version of the Psalms in this translation is that now used in the "Common Prayer" of the Episcopal church. In 1538, by special license, Coverdale published a quarto edition of the New Testament in English. The skill of the French printers, and the comparative cheapness of labor and materials at Paris, made King Henry desirous of printing an edition of the Bible in that city. Permission was granted by Francis I., then king of France, in the last named year, and Coverdale went thither to superintend it; but before the completion of the undertaking it was denounced by the inquisition, and the impression of 2,500 copies condemned to the flames. Owing to the cupidity of the officer to whom the execution of the sentence had been confided, a few copies were sold as waste paper, and so preserved. These, with presses, types, and printers, were shortly after transported to England, and used under the superintendence of Coverdale in printing the "Great Bible" of Cranmer. Coverdale held the office of almoner to Queen Catharine Parr, and officiated at her funeral in 1548. In 1551, when appointed to the bishopric of Exeter, the customary payment of first fruits was remitted to him, at the solicitation of Cranmer, on account of his poverty. On the accession of Queen Mary, and the consequent restoration of the Roman Catholic religion, Coverdale was deposed from his bishopric, and escaped a long imprisonment only on condition of leaving the country. He found an asylum, first in Denmark, and afterward in Geneva, where he assisted in the English translation known as the "Genevan Bible." He returned to England on the accession of Elizabeth, but was not restored to the see of Exeter. His last days were spent in translating the writings of the continental reformers, and publishing original tracts in support of the principles of the reformation. The date of his death is uncertain, but he was buried in the church of St. Bartholomew, London, Feb. 19, 1568. On Oct. 4, 1835, was celebrated the 3d centenary of the publication of his Bible.

COVINGTON. I. A S. co. of Ala., bordering on Fla., drained by Conecuh and Yellow-water rivers; area, 1,240 sq. m.; pop. in 1850, 3,645, of whom 480 were slaves. The surface is uneven, and mostly occupied by pine forests, the lumber obtained from which forms the chief article of export. The soil is sandy and poor. In 1850 it produced 80,205 bushels of Indian corn, and 416 bales of cotton. There

were 9 churches, and 144 pupils in the public schools. Capital, Montezuma. II. A S. co. of Miss., drained by affluents of Leaf river; area, 680 sq. m.; pop. in 1850, 3,338, of whom 1,114 were slaves. Pine timber occupies portions of the surface, but it is not abundant. The soil is light and sandy, and in 1850 produced 108,920 bushels of Indian corn, 9,417 of oats, 51,849 of sweet potatoes, and 1,164 bales of cotton. There were 2 churches, and 126 pupils attending schools and academies. The county was named in honor of Gen. Covington. Capital, Williamsburg.

COVINGTON, a thriving city of Kenton co., Ky.; pop. in 1853, about 13,000. It stands on a beautiful plain on the Ohio river, opposite Cincinnati, and at the mouth of Licking river, on the other side of which is the town of Newport. It is regularly built, and in its general arrangement greatly resembles Cincinnati, of which it may be considered a suburb. Many persons doing business in Cincinnati have their residence here. Covington contains a number of cotton, woollen, silk, and tobacco factories, an extensive pork and beef packing establishment, a large city hall, 3 banks, 2 female academies, 10 churches, and the western theological college, a wealthy institution under the charge of the Baptists.

COW. See CATTLE.

COWELL, JOHN, an English civilian, born at Ernsborough, in Devonshire, in 1554; died at Cambridge, Oct. 11, 1611. He was educated at the university of Cambridge, where he subsequently became fellow, professor of civil law, and master of Trinity hall. In 1607 he published a general law dictionary, styled the "Interpreter," which, though displaying extensive erudition, involved him in much trouble, the house of commons having commenced a prosecution against him for maintaining in that work that a British monarch might make laws without the consent of parliament. The king, James I., however, interposed, and proceedings were stopped. Beside the above named work, Cowell also wrote "Institutes of the Laws of England."

COWES, WEST, a seaport town and watering place of the isle of Wight, Hampshire, England, situated on the W. side of the mouth of the river Medina, which enters the Solent channel nearly opposite the estuary called Southampton water; pop. in 1851, 4,786. It is finely situated on rising ground, and presents a handsome appearance from the harbor, with its houses rising one above another, its castle and crescent-shaped battery, and its modern villas crowning the eminence. It has a number of good hotels and lodging houses for summer visitors, an assembly room, a town hall, a mechanics' institute, 5 places of worship, the club house of the royal yacht squadron, which holds its annual regatta here, and a marine parade, which lies S. of the castle, and forms a fashionable promenade. The streets, however, are steep, narrow, and in many quarters disfigured by old and wretched dwellings. Its beautiful scenery, good situation, and facilities for sea-bathing at a fine beach very near the town, render it one of the most popular bathing places in England. The harbor is excellent, and there is constant steam communication with Portsmouth, Yarmouth, Southampton, &c. A brisk trade is carried on in provisions and other marine stores; wheat, flour, malt, barley, wool, and salt are largely exported to France, Spain, Portugal, and the Mediterranean; vessels of war, yachts, and other craft of superior sailing qualities, are built in considerable numbers. The registered shipping of the port, Dec. 31, 1856, showed an aggregate of 168 vessels, tonnage 7,683. Number of vessels entered during the year, 1,454, tonnage 62,048; number of vessels cleared, 519, tonnage 13,055.—EAST COWES, a small place, on the opposite bank of the Medina, communicates by ferry with the above town, of which it may be considered a suburb. It contains the custom house of the port, a church, a botanic garden, and a number of handsome dwellings. Osborne house, the marine villa of Queen Victoria, is in the vicinity.

COWETA, a N. W. co. of Ga.; area, 378 sq. m.; pop. in 1852, 12,498, of whom 4,823 were slaves. Value of real estate in 1856, $2,131,799. It is bounded N. W. by the Chattahoochee, and E. by Line creek. It has an uneven surface and a fertile soil, most of which consists of a sandy loam. Oak, hickory, and pine are the principal kinds of timber. In 1850 the productions were 10,369 bales of cotton, 516,910 bushels of corn, 93,104 of oats, and 94,357 of sweet potatoes. There were 27 churches, and 800 pupils attending academies and schools. A gold mine was worked here during the same year. The county was formed in 1826, and named in honor of Gen. William McIntosh, a half-blood Creek Indian and head chief of the Coweta villages. Capital, Newnan.

COWHAGE, bristly hairs from the pod of the *mucuna pruriens*, a perennial climbing plant, which grows in the West Indies and other parts of tropical America. The pod is imported for the sake of the hairs, which are used in medicine. They are sharp, penetrating spiculæ, which produce an intense itching sensation when handled. In the West Indies they were long since found to possess valuable qualities as a vermifuge, probably by penetrating and thus destroying the worms. They are consequently adopted in medical practice, and introduced into the pharmacopœias. The medicine is prepared by dipping the pods in molasses and scraping the hairs into this, until a mixture is obtained as thick as honey. Cowhage has also been applied as an external irritant by making it into an ointment with lard.

COWL (Sax. *cugle;* Lat. *cucullus*), a sort of hood, originally worn by all classes, and still retained by certain orders of monks. It consists of a conical covering for the head, attached to the robe or cloak, and sometimes made to draw over the shoulders also. According to Mabillon, it was at first the same

as the scapular. The Benedictines and Bernardines have 2 sorts, one black for ordinary occasions, and another white and very large for days of ceremony. The proper shape of the cowl has been the subject of long and bitter dissensions in the Franciscan order, which 4 popes exhausted every means to heal, and which were only remedied by time.

COWLEY, Abraham, an English poet, born in London in 1618, died at Chertsey, in Surrey, July 28, 1667. His father died before his birth, and he was brought up under the care of his mother, by whose solicitation he was admitted into Westminster school. Spenser's "Fairy Queen" first led him to turn his attention to poetry. A volume of his poems was published when he was 15 years old, including some of his compositions written at 10 years of age. While he was yet at school, he produced a comedy entitled "Love's Riddle," written in the pastoral strain. In 1636 he removed to Cambridge, and two years afterward published his "Love's Riddle," with *Naufragium Joculare*, a comedy in Latin prose, now totally forgotten. In 1643 he was ejected from Cambridge, on account of his political opinions and independence, and went to Oxford. He was strongly attached to the fortunes of Charles I., and in the struggle which followed was a devoted partisan of the royal cause. When Oxford was taken possession of by the parliament, Cowley followed the queen to Paris, and there became secretary to Lord Jermyn, afterward the earl of St. Albans; he was frequently occupied in writing and deciphering the secret letters that passed between the king and queen, an office of delicate nature and of great responsibility. He was absent from England all together upward of 10 years, and during that time he undertook some very perilous journeys to Jersey, Scotland, Flanders, Holland, and other countries. In 1656 he repaired secretly to England, but was arrested and only set at liberty on his giving bail for £1,000. In that year he published his poems, and in his preface appears to have inserted a passage suppressed in subsequent editions, which was thought to intimate a change in his loyal feelings, and he also speaks of his desire to "retire to the American plantations and forsake this world for ever." On the death of Oliver Cromwell he returned to France, where he remained in his former station until the restoration of the Stuarts. He was made a doctor of medicine at Oxford in 1657, but there is no reason to suppose that he ever practised. He considered a knowledge of botany indispensable to the medical profession, and retiring to the county of Kent, busied himself with gathering plants. He also wrote a Latin poem on plants in 6 books. When the restoration took place, Cowley looked for some substantial reward for his services in the royal cause, but he received nothing. He had been promised by Charles I., as well as by his son, the mastership of the Savoy, "but lost it by certain persons enemies to the muses." It is said that in revenge he altered a comedy, the "Guardian," and brought it out anew under the title of "Cutter of Coleman Street." It was harshly treated on the stage, and regarded as a satire on the royal party. He took the failure of his play considerably to heart, but denied that it was intended in any manner as a reflection on the royalists. This assertion, however, gained little credence, nor did he mend matters by the publication of an ode called the "Complaint," in which he bewailed his misfortunes, and styled himself the melancholy Cowley. He now left London, and secluded himself first at Barn Elms, a suburban village, and afterward at Chertsey in Surrey. In his retreat he was at first but slenderly provided for, but by the influence of the earl of St. Albans he obtained such a lease of the queen's lands as secured him a tolerable income. Although very highly esteemed as an author by Johnson, and by Milton even ranked with Shakespeare and Spenser, there is probably no English poet of equal pretensions less read at the present day. His "Essays" have great merit as agreeable specimens of prose composition. He was buried near Chaucer and Spenser in Westminster abbey, where in 1675 the duke of Buckingham erected a monument to his memory.—An edition of his "Works," with his "Life" by Bishop Sprat, was published in 1688 (folio), and his "Select Works," edited by Bishop Hurd, in 1772–'7 (3 vols. 8vo.).

COWLEY, Henry Richard Charles Wellesley, baron, a British diplomatist, born July 17, 1804, nephew of the first duke of Wellington, succeeded his father in the peerage, April 27, 1847. At an early age he entered the diplomatic service, and having been successively employed in the embassies of Vienna, Stuttgart, and Constantinople, he was sent as minister plenipotentiary to Switzerland in 1848, and afterward to Frankfort-on-the-Main, where he acted as minister to the German confederation. In 1852, when Napoleon became emperor, Lord Cowley was chosen to replace Lord Normanby as ambassador to France, and in concert with the earl of Clarendon attended the peace congress of Paris, which opened Feb. 25, 1856.

COWLITZ, Cowlitsk, or Cowelitsk, a S. W. co. of Washington territory, bounded S. W. by the Columbia, S. E. by the Calama, which separates it from Clark co., and intersected by Cowlitz river; area, 1,050 sq. m. Capital, Monticello.

COWPENS, a post village in Spartanburg district, S. C., near the border of North Carolina, in the neighborhood of which a signal victory was gained by the American forces, commanded by Gen. Daniel Morgan, over a British division under Col. Tarleton, Jan. 17, 1781. In the latter part of December, 1780, Morgan was directed by Gen. Greene to occupy the country between the Broad and Pacolet rivers in the Spartanburg district, and Cornwallis, then at Winnsborough, in Fairfield, apprehending that the important post of Ninety-six was menaced, despatched Tarleton with 1,100 choice troops,

comprising 350 of his famous legion and portions of the 7th and 71st regiments, with 2 pieces of artillery, to force Morgan either to fight or retreat into North Carolina. Tarleton commenced his march on Jan. 11, and moving with great rapidity reached the Pacolet on the evening of the 15th. Morgan had intended to dispute the passage of the river; but being inferior in cavalry, he deemed it prudent to retire toward Broad river. Tarleton pressed on in pursuit, and on the morning of the 17th came up with Morgan in an open wood known as Hannah's Cowpens, being part of a grazing establishment belonging to a man named Hannah. The American troops, about 1,000 in number, occupied 2 gentle eminences, on which they were drawn up by Morgan in 2 lines, the 1st composed of Carolina militia, with an advanced corps of volunteer riflemen under the command of Col. Pickens, and the 2d of Maryland regulars and Virginia riflemen under Lieut. Col. John E. Howard. In the rear was a reserve of cavalry, consisting of Lieut. Col. Washington's troop, 80 strong, and about 50 mounted volunteers under Major McCall. Tarleton, disregarding the fact that his troops were fatigued by a long night march, with characteristic impetuosity ordered an attack. The British advanced to the charge with loud shouts, receiving an effective discharge from the American riflemen, who in obedience to Morgan's orders fell back upon the 1st line. The latter stood firm until within bayonet thrust of their opponents, when they also fell back upon the 2d line, composed of continental troops, which was thus compelled to bear the brunt of the fight. Col. Howard at length, fearing that he might be outflanked, attempted to change his front to the right, the order for executing which was misinterpreted into one for a retreat, and the whole line was thrown into some confusion. At this moment Morgan ordered them to retreat to the eminence behind which the cavalry were posted. The British, feeling sure of victory, rushed forward in some disorder, when they were met by a fierce charge from Washington's dragoons. At the same time Howard's troops facing about gave them a deadly volley of musketry, which they followed up so effectively with the bayonet that in a few minutes the British line was broken, and cavalry, infantry, and artillery were in full flight. Tarleton endeavored in vain to reform his troops; a panic had seized upon them, and even his favorite legion, with which he had accomplished so many dashing exploits, galloped away without having crossed a sabre. Tarleton himself, with a small band of horsemen, made a precipitate retreat, hotly pursued by Col. Washington, by whom he was wounded in the hand. The British loss in this action amounted to more than 300 killed and wounded, and between 500 and 600 rank and file prisoners. The Americans had 12 men killed and 60 wounded. The spoils of the victors were 2 field pieces, 2 standards, 800 muskets, 100 dragoon horses, 70 negroes, and some baggage.

COWPER, Edward, an English inventor and improver of machinery, also favorably known as a lecturer on the mechanic arts, born in 1790, died in London, Oct. 17, 1852. During the greater part of his life he was a printer, and some of the most important improvements in machine printing are due to him. Among others may be mentioned the giving a diagonal action to the rollers on the self-acting inking tables. During the latter part of his life he was professor of mechanics and manufacturing arts at King's college. He wrote an elaborate article on a "Button," and delivered lectures on the London crystal palace, in 1851.

COWPER, William, lord chancellor of England, born at Hertford in 1664, died Oct. 10, 1723. He was called to the bar in 1688, the year of the revolution, in which he took part so far as to form a small company of volunteers, and set out to join the prince of Orange. After the settlement of the government he returned to his practice, and soon became the decided leader of the home circuit, with a large practice in the court of chancery. He entered parliament as a whig in 1695, and gained by his maiden speech the reputation of a consummate debater. The whig party having gained the ascendant in 1705, the great seal was committed to him as lord keeper, and the next year he was raised to the peerage and made lord high chancellor. His judicial business was transacted with credit, and his honorable disinterestedness is worthy of remembrance in having abolished the custom of "yearly gifts" from the officers and lawyers of his court, which prevailed there before his time as well as in the other courts of the kingdom, and which had produced to the chancellors some £3,000 per annum. He presided at the impeachment of Sacheverel, and soon afterward upon the defeat of the whigs resigned his office, went into opposition, and remained one of the chiefs of his party in council and debate until the accession of George I., when in 1714 he was again made lord chancellor. For some time he enjoyed the entire confidence of the king, and had an important share in the political direction of affairs during the settlement of the government under the new dynasty and the rebellion of 1715 in favor of the exiled family, but again resigned in 1718, in consequence of the feud between the king and the prince of Wales. He continued to take part in the proceedings of the house of lords as long as he lived. Although a lawyer and a judge of authority and respectable standing, his principal character in history is that of a politician, where he generally appears as the advocate of liberal principles, both in relation to secular and religious matters, but not always free from the errors and inconsistencies of the time. He was celebrated as an orator for his graceful and charming manner and delivery, with which he was said to captivate the hearts of his auditory; but he was nevertheless the mark for much political detraction, and the hero of a curious story circulated all over Europe by

the authority of Voltaire, that he married and lived at the same time with 2 wives, and wrote a little book in defence of the practice. Although there was apparently no other foundation for it than some early irregularities, it gave him the common nickname of "Will Bigamy."

COWPER, William, an English poet, born Nov. 15, 1731, at Great Berkhamstead, Hertfordshire, died at East Dereham, Norfolkshire, April 25, 1800. His father, the Rev. John Cowper, was one of the chaplains to George II. and nephew to the lord chancellor Cowper. His mother died when the poet was but 6 years of age, and the touching lines in which he recalls her memory show the deep impressions she had left on his mind. He was sent early to the day school of his native town, and went afterward to Westminster, where he suffered from the tyranny of older and stronger boys. At 18 he began to study law with a solicitor, Mr. Chapman, in whose house he slept for 3 years, but who set his student the example of paying little attention to his profession. He then took rooms in the Inner Temple, was admitted to the bar, and here for the next 12 years lived indolently, neglecting the law for literature and gay society. He formed literary acquaintances, wrote verses, and contributed several papers to the "Connoisseur." In his 31st year he formed an attachment for his cousin Theodora Cowper, sister of Lady Hesketh; but their union was forbidden by her father, first for prudential reasons, and then because of their consanguinity. Having received an appointment through his uncle, Major Cowper, as reading clerk to the committees of the house of lords, he seemed destined to ease and competence; but his natural timidity and nervousness interposed. He shrank from the thought of appearing before the lords, and when a new office was provided for him by the same kind relative, the clerkship of the journals to the same house, he was seized with a fresh alarm when called upon to stand an examination as to his qualification for the place, and in his mental excitement sought to destroy himself. He soon afterward became insane, and was removed by his relatives to an asylum at St. Albans under the care of Dr. Cotton. During the remainder of his life he experienced several long returns of mental alienation. He fancied himself destined to eternal woe. He shunned the society of his friends and near relatives, to find relief in that of strangers. In all his sufferings, however, his relatives watched over him with tenderness and provided for him a moderate support. At Huntingdon, whither he removed in 1765 from the care of Dr. Cotton, he met with the Unwin family, who received him into their house as a boarder, and for whom he formed a lasting regard. When, on the sudden death of her husband, two years afterward, Mrs. Unwin removed to Olney in Buckinghamshire, Cowper went with her; and here they occupied a house next that of the Rev. John Newton, curate of the parish, for whom he had previously contracted a high esteem. Olney is famous as the favorite residence of Cowper. Here he passed many years of his life, occupied with religious exercises and in active charity among the poor. Here, too, were written those poems that served to lighten his mental suffering, though they could never wholly relieve it. At the age of 50 (1782) he published the 1st volume of his poems, the subjects of several of which had been suggested by Mrs. Unwin. The volume was tolerably well received; but the ballad of "John Gilpin," which he wrote from a story told him by Lady Austen, gave him a wide renown. It was read to crowded audiences in London by Henderson the actor, and one publisher alone sold 6,000 copies of a print of John Gilpin on his famous ride. The ballad had been published anonymously, and lay for 3 years neglected until suddenly it caught the attention of the public. Lady Austen next suggested to him the "Task," which appeared in 1784, and gained general popularity. The amiable, intelligent Lady Austen, and the older and more austere Mrs. Unwin, were now his constant associates; but jealousy, it is said, arose between them, and Lady Austen left Olney in displeasure. He next translated Homer in blank verse, and published it by subscription in 1791. His last literary occupation was a translation of Milton's Latin poems, with a commentary on his works; but this performance the condition of his mind prevented him from completing. His faithful friend Mrs. Unwin having become paralytic, his cousin Lady Hesketh came to take charge of his household; but in 1795 he removed from Olney with Mrs. Unwin to the house of his relative, the Rev. Mr. Johnson, at Tuddenham, and finally to East Dereham. A pension of £300 had been settled upon him by the king, chiefly through the active solicitations of the amiable poet Hayley; but Cowper, when it was announced to him, showed no marks of pleasure. In 1796 Mrs. Unwin died; the poet, it is said, looked in silent agony upon her corpse, and then turning away, never afterward mentioned her name. A slight recovery of his mental powers enabled him in 1799 to revise his Homer, and to write his last poem, the "Castaway," a picture of his own sad fate, but he died of dropsy in the spring of the following year.—Cowper's writings are original, truthful, and striking. In poetry he was one of the first to break away from the despotism of Pope, and invent an original rhythm. He is never melodious, but always natural and at his ease. He loved nature, flowers, animals, and rural life, and paints scenery with great power. His descriptions are sometimes coarse, but always clear and effective. The moral teaching of his poetry is high, and he strove to force upon his material age the noblest conceptions of the spiritual and the divine. With this religious turn of thought he joined humor and forcible satire. He translated Homer with more accuracy than Pope, but his blank verse wants harmony and grace. His prose is excellent, and his let-

ters are not surpassed by any in the language. Here, in his happier moods, all is playful humor, ease, gayety, simplicity, and wisdom. His mind seems to break from its clouds into moments of perfect sunshine. In character he was pure, his disposition amiable; he gained the love and respect of gifted men and virtuous accomplished women; he was charitable and active in doing good; tender and confiding to his friends, and capable of unchanging affection. So good a man might well have looked for happiness both here and hereafter; but it was Cowper's singular fate to pass a lifetime in despair. Hope was an impulse he never knew or never ventured to indulge. His appearance was intellectual and well bred, his manner pleasing, and his whole life that of a tasteful recluse. He cultivated flowers, and watched with interest the progress of his garden. He petted tame leverets and immortalized them in verse. He was careful of his dress, and though afraid of strangers, took pleasure in a narrow circle of well bred, intelligent associates. His clouded mind, his mental agonies, and his generous kindly nature, endeared him to his friends, who loved, pitied, and admired him; sentiments that posterity must continue to share.—The life of Cowper was first written by William Hayley, for an edition of his posthumous writings (Chichester, 1803–'6). It has also been written by Thomas Taylor (London, 1835); by the Rev. T. S. Grimshawe, for an edition of his works and correspondence (London, 1836); by H. F. Cary, for an edition of his poems, including his translations of the Iliad and Odyssey (London, 1839); by Sir Harris Nicolas, for an Aldine edition of his poems (London, 1843); and by Robert Southey, for a complete edition of his works (London, 1833–'37). The last biography and edition are much the best, and have recently been republished, with additional letters, in Bohn's "Standard Library," in 8 vols.

COWRY, the common name of the shell-fish *cypræa*, of the family *cypræidæ*. Many species are met with most abundantly in the warm seas of the eastern hemisphere. Those of special interest are the *C. annulus*, used by the Asiatic islanders to adorn their dress, for sinkers to their fishing nets, and for barter; and the *C. moneta*, or money cowry. The latter is an eastern and Pacific shell, and is an important article of trade, being largely imported into Calcutta and Bombay from the Laccadive and Maldive islands. Their value in Bengal used to be rated at 2,400, then at 2,560, but now more than 3,200 to the rupee, the worth of which is about 50 cents. They are largely imported into Liverpool, about 60 tons being received in 1848, and nearly 300 tons in 1849. Their rates are often quoted upon the price currents of New York and London. They are sent to the western coast of Africa for barter with the natives. A species of this family called the *C. princeps*, "the brindled cowry of the Persian gulf," is very highly prized by conchologists for its rarity and beauty. Only two specimens are known; one is in the British museum, and the other was sold a few years since in London, at the sale of the collection of the late earl of Mountnorris, for £40. A specimen of the *C. umbilicata* was sold in 1850 for £30. The cowries, from the great variety and beauty of the markings upon their smoothly-polished surface, have long been in demand among civilized and uncivilized nations for ornaments to their dress and habitations.

COX. I. David, an English landscape painter, born at Birmingham, April 29, 1793. His paintings, chiefly on Welsh subjects, are in water colors, small, and apparently rapid and careless, but full of the impression and effect of nature. He succeeds best in sketching rain and wind, bursts of sunshine on dark moors, the dank herbage of marshes, and rural scenery beneath the threatening storm. He published in 1814 what is still considered the best "Treatise on Landscape Painting in Water Colors." His son David is also a painter of some ability. II. Francis Augustus, D.D., an English clergyman of the Baptist denomination, born March 7, 1783, died in Sept. 1853. He was graduated at the university of Edinburgh, and commenced his pastoral labors at Hackney, near London, in 1811. Here he principally resided, and beside the care of a large congregation and various other employments, he took an active share in procuring the establishment of the London university. He attained a prominent position in his denomination, and was chosen about 1840 to make an official visit to the United States, for the purpose of drawing closer the bonds of fraternal feeling between the Baptists of the two countries. Dr. Cox was a contributor to the "Eclectic Review" and other periodicals, and published a "Life of Melanchthon," "Female Scripture Biography," and other works. III. Richard, bishop of Ely, born at Whaddon, Bucks, about 1500, died in 1581. He was educated at Cambridge, and when Christchurch college at Oxford was founded by Cardinal Wolsey, was chosen one of its officers, but afterward forfeited this position and was lodged in prison, in consequence of his adoption of the doctrines of Luther. Upon the accession of Edward VI. he became tutor to the king, chancellor of Oxford, canon of Windsor, dean of Westminster, and a privy councillor. When Mary began her reign he fled to the continent; but when Elizabeth succeeded, he returned to England, and was made bishop of Ely, which see he held for 21 years. He took an active part in the preparation of the liturgy. The revision of the Gospels and the Acts of the Apostles, in that edition of the Scriptures called the "Bishops' Bible," was by him. He was also one of the compilers of Lily's "Accidence." IV. Samuel Hanson, an American divine, born at Leesville, N. J., Aug. 25, 1793. In 1811 he commenced the study of the law at Newark, N. J., but abandoned it at the end of one year to take up that of theology, and was ordained by the presbytery of New Jersey, July 1, 1817. In

the autumn of 1820 he removed to New York to assume the charge of the Spring street Presbyterian church. After gaining here the reputation of an ardent and striking preacher, he sailed for Europe in 1833 to recruit his health, and after his return took the chair of professor of sacred rhetoric at Auburn, N. Y., in the autumn of 1834. In May, 1837, he removed to Brooklyn as pastor of the first Presbyterian church, and remained in this connection until 1854, when he was obliged by infirmity of the voice to give up his charge, and retired to Owego, N. Y. Having had the degree of D.D. conferred on him in the summer of 1825 by Williams college, he indignantly repudiated, in a letter to the "New York Observer," Nov. 16, 1825, the "semilunar fardels." Having lent his countenance and sympathy to the foundation of the American anti-slavery society, he was one of the sufferers by a mob excited in opposition, and had his house and church sacked, July 10, 1834. At that time he passed for an agitator upon all topics; and always throwing himself impetuously into the service of every cause which he has espoused, he has successively appeared as the zealous advocate of abolition, temperance, colonization, new school Presbyterianism, the evangelical alliance, &c. Of late years, however, he has changed his views on the slavery question, and has identified himself with the conservative treatment of that question. As a writer and preacher he abounds in quaint conceits and learned allusions, with a substratum of strong common sense and ardent feeling, and holds a high rank in the religious and intelligent community. He was moderator in 1846 of the general assembly of the Presbyrian church, and has frequently been delegated to attend the religious anniversaries in London. He is the author of "Quakerism not Christianity," "Interviews Memorable and Useful, from Diary and Memory," and other publications.

COXCIE, or Coxis, Michael, a Flemish painter, born at Mechlin in 1497, died in Antwerp from the fall of a scaffolding in 1592. He was a pupil of Bernard van Orley, and went afterward to Rome, where he acquired celebrity and was much employed as a fresco painter. He married in Italy, and after his return to his own country his works were in great demand, and he acquired a large fortune by them. Many of them were taken to Spain, and he had 3 palaces or houses full of the most valuable at Mechlin. He is now better known by his copy of the "Adoration of the Lamb," by the brothers Van Eyck, in the church of St. Bavon at Ghent, than by his original productions. This copy was made for Philip II. of Spain, and cost 2 years of constant labor, for which the artist was paid 4,000 florins. It was finished in 1559. Complaining that he could not find a blue good enough to paint the mantle of the Virgin with, the king wrote to Titian for some ultramarine, of which, when it came, Coxcie used to the value of 32 ducats on the mantle alone. The copy was painted with extreme care, and was for a long time kept in the chapel of the old palace at Madrid, whence it was sent to Brussels by Gen. Belliard during the French occupation of Spain. It was in several parts, which are now scattered in the royal gallery of Berlin, in the Pinakothek at Munich, and in the collection of the king of Holland. Without much originality, Coxcie yet conferred a service upon the art in his native country by introducing there the knowledge of the Italian masters and their style. He is distinguished for lightness, grace, and an agreeable individuality. Among his best productions are the illustrations of the fable of Psyche, which were engraved by Agostino Veneziano, and have furnished the models for innumerable paintings on glass.

COXE. I. Arthur Cleveland, D.D., an Episcopal clergyman, son of the Rev. S. H. Cox, born at Mendham, N. J., May 10, 1818. He was graduated in 1838 at the university of New York, took orders in 1841, and has been settled successively at Morrisania, Hartford, and Baltimore, in which last named city he is now (1859) the rector of Grace church. He has written "Christian Ballads," a volume of religious poems (New York, 1840), "Saul, a Mystery," and other poems, beside a volume of travels in England (1856), and a collection of sermons (1855). II. Tench, an American writer on political economy, born in 1756, died in Philadelphia, July 16, 1824. He was the author of "An Inquiry into the Principles of a Commercial System for the United States" (1787), "View of the United States" (1794), "Thoughts on Naval Power and the Encouragement of Commerce and Manufactures" (1806), "Memoir on the Cultivation, Trade, and Manufacture of Cotton" (1807), "On the Navigation Act" (1809), "On the Arts and Manufactures of the United States" (1814). III. William, archdeacon of Wilts, an English historical and biographical writer, born in London in March, 1747, died at Bemerton in June, 1828. He was elected a fellow of King's college, Cambridge, in 1768, and in 1771 was appointed to the curacy of Denham. Shortly after this he commenced a series of extended visits to the continent, in the capacity of private tutor to young members of the nobility, which, with occasional intervals for literary or professional labor, embraced a period of more than 20 years. The result of his observation and researches was given to the world in a number of elaborate books of travel, and of history and biography. In the former department he published between 1779 and 1789 "Travels into Poland, Russia, and Denmark," and "Travels in Switzerland," beside some miscellaneous works on Russian discoveries, on hospitals in northern Europe, and other subjects. In 1798 appeared his "Memoirs of the Life and Administration of Sir Robert Walpole," accompanied by many valuable state papers, of which Pitt observed that it gave him his first correct notion of the character of Sir Robert. His next important publication, "History of the House of Austria" (which forms a part of Bohn's "Stand-

ard Library"), is carefully and impartially written, and is still regarded as a standard authority. It was succeeded by "History of the Kings of Spain of the House of Bourbon," in 1813, "Memoirs of John, Duke of Marlborough," in 1817–'19, "Memoirs of the Administration of the Right Hon. Henry Pelham," published posthumously in 1829, and by a variety of minor publications. He was appointed archdeacon of Wilts in 1805, and during the last 7 or 8 years of his life was afflicted with total blindness.

COYPEL. I. Noël, a French painter, a successful imitator of Poussin, born in 1628, died in 1707. Among his most celebrated pictures are the "Death of Abel" and the "Assumption of the Virgin," the latter in the hotel of the Invalids. II. Antoine, a son and pupil of the preceding, born in 1661, died in 1722. He was inferior to his father, but graceful in the treatment of his subjects, and a man of literary accomplishments. He was appointed painter to the king in 1716. His principal works are the "Assumption," in the church of Notre Dame, "Christ Curing the Blind," and "Christ among the Doctors." Some of his etchings are executed in a masterly manner. The "Numismatic History of the Reign of Louis XIV.," chiefly from his designs, is a work as remarkable of its kind as his frescoes of the chapel at Versailles. III. Noël Nicolas, stepbrother of the preceding, born in 1692, died in 1735, also painted many works for the churches of Paris, of which the best are the ceiling of the chapel of the Virgin in the church of St. Saviour, and the "Assumption" in the same chapel. IV. Charles Antoine, son of Antoine, born in 1694, died in 1752, chiefly excelled as painter of portraits, the best of which is that of Adrienne Lecouvreur.

COYSEVOX, Antoine, a French sculptor of Spanish origin, born in 1640, died in Paris, Oct. 10, 1720, produced several fine statues of Louis XIV., a statue of Condé, and of other eminent persons. Among his best works are the tombs of Mazarin and of Colbert, the monument of Lebrun, and 2 statues of a flute-player and Flora, now in the gardens of the Tuileries.

COZZENS, Frederic Swartwout, an American author, born in New York, March 5, 1818. He was educated in his native city, and has always resided there. In 1853 he collected a series of articles, which he had previously contributed to the "Knickerbocker Magazine," in a volume entitled "Prismatics, by Richard Haywarde." The *nom de plume* which he assumed was the name of one of his ancestors, an English Moravian missionary in America. In 1856 he published the "Sparrowgrass Papers," consisting of sketches which had before appeared in "Putnam's Magazine," describing the rural life of a cockney. Mr. Cozzens is a leading wine merchant, and publishes in connection with his business a periodical entitled the "Wine Press," for which, as well as for other publications, he has written interesting essays on the culture of the grape. In 1858 Mr. Cozzens attended the copyright congress of Brussels as delegate of the New York publishers' association.

CRAB, a crustaceous animal of the tribe *brachyura* and genera *cancer*, *lupa*, and many others, several species of which are common on the coast, and serve, like the lobster, for food. The most common is the *lupa dicantha* of Milne-Edwards, found most abundantly south of Cape Cod, and especially in Chesapeake and Delaware bays. Its feet are flattened, its teeth long and projecting like spines. From the color of its long hands it is sometimes called the violet crab, though the color of the body is greenish. In the summer months it is regarded as a great delicacy on the shores of the Chesapeake. A number of the species of the smallest crabs are known only as they are found in the intestines and maws of the cod, haddock, and other fish, to which they seem to furnish one of the principal sources of food. Another little crab, the *pinnotheres ostreum*, unprotected by a shell of its own, finds a shelter within those of the oyster, mussel, pinna, &c., which it does not appear to molest; indeed, it is supposed by some that it affords aid to the shellfish in securing the prey which nourishes both. This was the opinion of Pliny, and of later naturalists also. Others state that in the case of the pinna, at least, the little crab warns the shell fish of danger when its enemy the cuttle fish approaches to devour it. The little crab is often found with the oysters cooked for the table. Several species of the genus *pagurus* are also unprovided with a shell of their own; but these seek for some empty univalve shell; and an individual finding one which on trial fits his size, he takes possession of it, and drags it about with him on the sands, till his enlarged dimensions cause him to seek a more capacious tenement, or till a stronger crab, driving him out, suddenly slips in, and leaves him to look for another. These are known as hermit or soldier crabs. In Jamaica they pass into the interior several miles from the sea, carrying with them their coverings of marine shells.—Beside the salt-water crabs, there are others, as the thelphusians, that live on the banks of rivers and in humid forests, burrowing in the ground. In Italy and further up the Mediterranean these are eaten, particularly in the season of Lent. There are others also in warm climates of terrestrial habits, one group of which is called *ocypoda*, swift-footed, from their rapid running, which is such, as Cuvier states, that a horseman has some difficulty in overtaking them. The *O. arenaria*, or sand crab, of Catesby, is an American specimen of this genus, found in the West Indies and on the mainland. During the summer they live in holes on the sea-shore just above high-water mark, retiring into them during the day and coming out at night. When disturbed they run very rapidly, threatening at the same time with their elevated claws. At the close of the summer they emigrate in troops into the interior, and, finding a convenient place for passing the winter, dig holes into which they bury them

selves, and so completely hide the entrance to their retreats, that no indication of them is seen upon the surface. In the spring they reappear, and return to the sea-shore. They have a singular habit in their nocturnal excursions of entering into the houses, the doors of which in the warm nights are often left open, and taking possession of small articles of clothing, as cravats, collars, stockings, &c. If disturbed in their pilferings, they scramble away, making a great clattering upon the floor; the articles that disappear with them are usually effectually concealed in their holes. They are often seen in great numbers in the roads, and it is curious to observe their rapid sidelong retreat, as one is riding by on horseback, and when overtaken how they run as rapidly back the other way without turning round. In the Moluccas a crab is described by the name of purse or robber crab (*pagurus latro* of Fabricius), which is said to feed upon fruits as well as flesh, and to climb the palm tree called the *pandanus odoratissimus*, to eat the small cocoanuts it bears. They are seen in great abundance in Lord Hood's island in the Pacific. When met in the road they set themselves in a threatening attitude, making a great snapping with their pincers and retreating backward.

CRAB APPLE. See Apple.

CRABB, George, an English barrister and philologist, born at Palgrave, Dec. 8, 1778, died at Hammersmith, Dec. 4, 1854. Intended for the medical profession, his delicate nervous organization made him incompetent to follow it. He devoted himself to teaching, studied in Germany, and published on his return German text books, which were long in use. In 1821, after having been married 22 years, he was graduated at the university of Oxford, with reputation for mathematical attainments. He was 51 years of age when he was admitted to the bar. His offensive manners prevented his success as a practitioner, but as an author he made several contributions to legal literature, which became standard works. Among these is a "History of English Law." He is most generally known by his treatise on "English Synonymes," explained with copious examples, published in 1816 (7th edition in 1844, after which the book was stereotyped). He was the author also of a historical and of a technological dictionary.

CRABBE, George, an English poet, born at Aldborough, in Suffolk, Dec. 24, 1754, died at Trowbridge, in Wiltshire, Feb. 3, 1832. His father, who was a collector of salt duties, exerted himself to give his son a superior education. At the age of 14 years, having made some progress in the study of mathematics and the classics, George was destined to the medical profession, and was apprenticed to a surgeon near Bury St. Edmund's. Three years later he was transferred to another surgeon at Woodbridge, with whom he completed his apprenticeship. His father was a subscriber to a "Philosophical Magazine," the last page of which, devoted to poetry, he was accustomed to tear off before sending the numbers to be bound. These rejected sheets had first excited the poetical tastes and powers of his son, who, both during his school days and amid the pursuits of surgery, made many ambitious attempts at versifying. While at Woodbridge he competed successfully with a poem on "Hope" for a prize offered by the "Lady's Magazine," to which he continued to contribute. In 1775 his first separate publication, a poem on "Inebriety," was issued anonymously at Ipswich. He soon after repaired to London to pursue his medical studies, but returned within a year, with his pecuniary resources exhausted. Never pleased with his profession, he soon determined to abandon it for literary adventure in London, and, provided with a loan of £5, he worked his way in a sloop from Aldborough to the metropolis, where he arrived in 1780. His first poetical pieces found no publisher; and his first printed poem, the "Candidate," which appeared anonymously in that year, was coldly received, and brought him no profit in consequence of the immediate failure of his publisher. His letters to Lord North, Lord Shelburne, and Lord Thurlow, enclosing some of his poems and asking assistance, received no answer. Threatened with arrest, he applied without an introduction to Edmund Burke, at whose door he left a simple and manly letter, and then calmed his agitation by walking Westminster bridge backward and forward throughout the night. From his kind reception by Mr. Burke begins his success in literature. He was received into the family of the statesman, was introduced to Fox, Reynolds, Johnson, and his other distinguished friends, and had the advantage of his criticism and advice concerning the poem of the "Library," which was published in 1781 (2d edition in 1783), and which was favorably noticed. Lord Thurlow, with tardy generosity, now invited him to breakfast and presented him with a bank note for £100. By Mr. Burke's recommendation, he qualified himself for holy orders, was ordained a deacon in 1781, and a priest in the following year, and after a short experience as curate in his native parish, received the situation of chaplain to the duke of Rutland at Belvoir castle. In 1783 he published the "Village," which had been revised both by Mr. Burke and Dr. Johnson, and obtained immediate popularity, some of its descriptions, as that of the parish workhouse, being copied into nearly all periodicals. Lord Thurlow, declaring that he was "as like to parson Adams as twelve to a dozen," presented him in 1785 to two small livings in Dorsetshire, where, having married a lady who was the object of his early love, he lived in retirement. After the publication of the "Newspaper" in that year he did not resume authorship till 1807. He exchanged his livings in 1789 for others in the vale of Belvoir, where he resided most of the time till after the death of his wife in 1813, when he was preferred to the rectory

of Trowbridge. He assigned the death of his distinguished friends and advisers as his reason for publishing nothing, and passed his time in domestic enjoyment, in various studies of natural history, especially of botany, in educating his sons, in writing three novels which he afterward burned, and in fulfilling his professional duties. In 1807 his "Parish Register," which had been read and approved by Mr. Fox, was received with universal approbation, and was followed in 1810 by the "Borough," and in 1812 by "Tales in Verse." The latter years of Crabbe were occupied with the conscientious discharge of his duties to his parishioners of Trowbridge, by whom he was beloved, with studies of botany and geology pursued with increasing interest, and with occasional visits to London, and associations with a younger generation of poets, among whom were Moore, Rogers, Campbell, Scott, Wordsworth, and Southey. In 1819 he completed his last publication, the "Tales of the Hall," for the copyright of which and of all his previous works he received from Mr. Murray the sum of £3,000. In 1822 he visited Sir Walter Scott at Edinburgh, then in the midst of tumultuous preparations for the king's visit, and the biographer of Scott regrets that the two poets had not rather met among the books, and trees, and simple peasants of Abbottsford. His health began to decline in 1828, but his mind still retained its clearness and cheerfulness. The shops of Trowbridge were closed on the days of his death and funeral, and his parishioners erected a monument to his memory in the chancel of their church. He had spent for many years the principal part of his professional income in charity.—The finest productions of Crabbe, and sure foundations of his fame, are the "Village," "Parish Register," and some of his shorter tales, which are unrivalled for their severe and minute descriptions of humble life. The whole force of his genius, rarely diverted by bright ideal scenes or pictures of elegance and refinement, was bent upon delineating the circumstances and anatomizing the characters of poverty, vice, and misery. He is styled by Byron "nature's sternest painter, yet the best;" and though he flattered the poor by no Arcadian pictures, he was far from being their satirist. The amenities of the refined society which he enjoyed in mature manhood never occupied his imagination so much as the reminiscences of struggle, suffering, passion, and disaster with which his youth was familiar; and it was with deep sympathy that he described the ruined and friendless inmates of the workhouse, explored the haunts of smugglers and gypsies, wrote of erring and crazed maidens, and lingered over the darkest forms and refuse members of humanity. But though his delineations, with their Dutch minuteness and accuracy, always reveal tenderness and benevolence rather than harshness in the poet, they yet sometimes become wearisome and displeasing, failing to excite an interest in the gloomy subjects which they expose. A complete edition of his poetical works in 8 vols., the first of which contained his life written by his son, with his letters and journals, was published by Murray, in London, in 1834, and republished in one vol. in 1847.—George, an English clergyman, eldest son of the preceding, born at Strathern, near Belvoir castle, in 1785, died at Bredfield, Sept. 16, 1857. He was educated at Cambridge, was for many years curate of Pucklehead, and afterward vicar of Bredfield, published in 1840 a work entitled "Outlines of Natural Theology," and is chiefly known for his interesting biography of his father, which first appeared in 1834.

CRABETH, Dirk and Wouter, two brothers, natives of Gouda, in Holland, celebrated masters of painting on glass, lived in the 16th and the beginning of the 17th century. They painted the windows of St. John's church at Gouda, which are considered the most finished productions ever executed in that branch of art, and also the windows of other churches in Belgium and Paris, and probably also Spain. The two brothers were excessively jealous of each other, Wouter being superior in correctness and neatness of design, and Dirk in brilliancy of coloring.

CRACOW, formerly the capital of independent Poland, from 1815 to 1846 of the republic of the same name, now of a western circle of Galicia, and seat of a bishopric, is situated in a plain surrounded by hills, on the left bank of the Vistula, which there becomes navigable, and is crossed by a new massive bridge, connecting the city with the suburban town of Podgorze; lat. 50° 3′ N., long. 19° 55′ E.; pop. about 40,000, of whom nearly ⅓ are Jews. It consists of the city proper and several suburbs, the chief of which are the Kleparz, Stradom, and Kazimierz, the latter on an island of the Vistula, inhabited almost exclusively by the Jews, who have there 7 synagogues. Except this part, which is mostly a narrow and gloomy abode of misery, Cracow, with its old castle, once the residence of the kings, on the top of the Wawel, its large central square, its numerous churches, chapels, turrets, and steeples, offers the aspect of a handsome and picturesque old city; though several conflagrations, of which that of 1850 was one of the most destructive, have changed parts of it, and the ancient fortifications have been converted into modern encircling promenades. The royal castle, whose history is connected with that of the legendary Krakus and his daughter Wanda, of the Piasts and Jagiellos, having been destroyed by 2 conflagrations, restored by King Augustus II., fortified under the direction of Dumouriez, afterward the French general, in 1768, and repaired by the Austrians, has finally been converted by the latter into barracks for the garrison of the city. But the beautiful Gothic cathedral of the ancient residence still contains, in its numerous and splendid chapels, the tombs and monuments of St. Stanislas, whose remains are preserved in a silver coffin, of Casimir the

Great, Jagiello and his wife Hedvig, the 3 Sigismunds, Stephen Bathori, John Sobieski, Copernicus, Prince Poniatowski, Kosciuszko, Dombrowski, Arthur Potocki, and other kings, queens and celebrated men of Poland. Its bell, cast in 1520, its archives and library, as well as the royal insignia, preserved in the vaults, are also shown to visiting travellers as worthy of their curiosity. Beside the cathedral, Cracow has more than 70 Roman Catholic churches, numerous convents and chapels, and one Protestant church. Other remarkable buildings are the episcopal palace, with a museum of Sarmatian antiquities, the city hall, and the Jagiello university. The latter, founded by Casimir the Great, and completed under Ladislas Jagiello, was for centuries one of the most flourishing institutions of Europe, but lost its importance through the influence of the Jesuits, and having been reorganized in 1817, had again to suffer restrictive alterations in 1833. A library containing numerous old books and valuable manuscripts, a cabinet of natural history, a botanical garden and observatory, belong to it. Cracow has also a number of other institutions for public education, arts, sciences, and benevolence. In the vicinity of the city, the hill of Wanda, which commemorates the patriotic suicide of the daughter of Krakus, the Bronislawa (glory of arms), with a mound 150 feet high, erected in memory of Kosciuszko, and Lobzow, a summer residence built by Casimir the Great, attract the attention of travellers and patriots. The commerce of Cracow, though greatly decreased since the fall of independent Poland, and especially since the annexation to Austria, is still considerable. It is still a centre of trade between Russian Poland, Galicia, and Hungary, and a chief depot for Hungarian wines, salt, and wax. The celebrated salt mines of Wieliczka are a few miles distant from Cracow. Railroad lines connect it with Warsaw, Berlin, Vienna, and the interior of Galicia.—The foundation of Cracow is attributed by the legends of Poland to Krakus, a Slavic chief, who is supposed to have lived about the year 700. Under Ladislas Lokietek (the Short), who was crowned here in 1320, it became, instead of Gnesen, the capital of Poland. This dignity it maintained down to the reign of Sigismund III., who made Warsaw the seat of the court and government (1609). The kings of Poland, however, still continued to be crowned in the cathedral of Cracow. It was conquered in 1039 by the Bohemians, in 1241 by the Tartars, in 1655 by the Swedes under Charles X., in 1702 by Charles XII., and in 1768, after having for some time supported the cause of the confederation of Bar, by the Russians. After the fall of Kosciuszko, who made Cracow the starting point of his revolution, it was, on the last partition of Poland (1795), taken by Austria. In 1809 it was annexed, together with western Galicia, to the duchy of Warsaw, which had been created 2 years before by Napoleon. After the fall of this emperor it was erected by the congress of Vienna, together with a small but fertile territory of about 500 sq. m. on the left bank of the Vistula, bounded by Russian Poland, Galicia, and Prussian Silesia, into an independent and neutral republic, under the protection of Russia, Austria, and Prussia. This miniature state, the last remnant of Polish independence, had a representative assembly, which held sessions in the last month of every year, and an executive senate headed by a president, who was elected for 3 years by the assembly, and confirmed by the protecting states. It contained about 150,000 inhabitants, of whom more than $\frac{1}{10}$ were Jews. The latter, however, enjoyed no civil rights, and were also subject to many humiliating mediæval restrictions. Grain, excellent fruits, cattle, coal, iron, and sulphur, and the reviving commerce of Cracow, were the chief sources of wealth. During the Polish revolution of 1830–'31, Cracow was under the influence of the national party, and many of its inhabitants fought in the ranks of the Polish armies. Having become a place of refuge to a small part of the corps of Rozycki toward the close of the war, it was occupied by the Russian general Rüdiger. The republic was now purged by the 3 protecting powers of all revolutionary elements, and finally reorganized in 1833. But new national agitations brought about another military occupation in 1836, this time executed by troops of all the 3 powers. This was followed by the expulsion of more than 500 persons, who were escorted to Trieste, to be transported from that port to America. Scarcely had the troops retired, when new conspiracies, and the assassination of a Russian spy, served in 1838 as a reason for a fresh occupation by the Austrians, which lasted till 1841. The revolutionary outbreak of Feb. 1846, which was prepared by a most extensive conspiracy for simultaneous action in all the provinces of ancient Poland, was for a moment successful in Cracow alone. The Austrians, who had again occupied the city, were driven beyond the Vistula, the restoration of Poland as a democratic republic was proclaimed, and a provisional government organized under Tyssowski as dictator (who died at Washington in 1857). But the early detection of the conspiracy in the duchy of Posen, the easy suppression of the outbreak in Russian Poland, and particularly the great catastrophe in western Galicia, where the peasantry massacred the insurgent nobility with their followers and families, soon annihilated the hopes of the friends of Poland. Three armies were approaching. Thus pressed, the small body of Poles surrendered to the Prussians (March 3), and the republic of Cracow was soon after annexed to Austria by a resolution of the 3 protectors. Thus the stipulation of the congress of Vienna, which guaranteed the "perpetual freedom and independence" of the last small remnant of Poland, was set aside by 3 out of 8 contracting powers, without the consent of the others. The event was announced as a *fait accompli* by Prince Metternich, and remained so in spite of the

protests of the governments of England and France, the clamors and indignation of the western press, and the vehement speeches of Count de Montalembert in the French chamber of peers. The movements of 1848 but slightly disturbed the peace of Cracow. An extensive system of fortifications, undertaken by the Austrians, is now in course of completion.

CRAFTS, Samuel Chandler, governor and U. S. senator of Vermont, born at Woodstock, Windham co., Conn., Oct. 6, 1768, died at Craftsbury, Vt., Nov. 19, 1853, was graduated at Harvard university in 1790, and removed to Vermont soon after the state was admitted to the federal union. He was elected town clerk of Craftsbury in 1792, and held that office for 37 successive years. In 1800 he was appointed assistant judge of Orleans county court, and so continued till 1810, when he was appointed chief judge of the county court, holding that office till 1816. From 1796 to 1815 he was register of probate for Orleans district. In 1825 he was again appointed chief judge of the county court, in which office he remained 3 years, and from 1836 to 1838 he was clerk of the county court. In 1793 he was elected a delegate to the convention which met at Windsor to frame a state consitution. In 1796 he was elected a member of the house of representatives, and was re-elected in 1800, 1801, 1803, and 1805. In 1798 and 1799 he was clerk of the general assembly. In 1828 he was elected governor of Vermont, and reëlected in 1829 and 1830. In 1829 he was a member of the constitutional convention, of which body he was elected president. He was elected a representative in congress in 1816, and held that office for 8 successive years. In 1842 he was appointed by Gov. Paine a senator in congress to fill a vacancy. When the general assembly was convened, he was continued in the U. S. senatorship till the close of the term by the election of that body. With the termination of this office (March 3, 1843) his active public career was closed. In June, 1802, while there were but a few log huts on the site of the present city of Cincinnati, he commenced a tour of observation to the lower Mississippi, and, in company with Michaux the younger, made a botanical reconnoissance of the valley of the great West in canoes and arks at a time when there were no steamboats on that river.

CRAFTS, William, an American lawyer and author, born in Charleston, S. C., Jan. 24, 1787, died at Lebanon Springs, N. Y., Sept. 23, 1826. He was graduated at Harvard college in 1805. Choosing the legal profession, he began to practise in Charleston, and his eloquence made him a most successful advocate, especially in criminal cases. During several sessions he was a member of the state legislature. As editor of the Charleston "Courier," he contributed to that journal a large number of graceful essays suggested by topics of the day. He was a favorite orator on public occasions, and in 1817 delivered the Phi Beta Kappa address at Cambridge. He wrote a few poems, chiefly on local subjects, among which are "Sullivan's Island;" the "Raciad;" a "Monody on the Death of Decatur," an improvisation published on the day after the news of the commodore's death was received; "Kitty," a companion piece to Halleck's "Fanny;" the "Sea Serpent, or Gloucester Hoax," a drama in 3 acts, founded on the reputed capture of the sea serpent at Gloucester, which proved to be a horse mackerel of mammoth proportions; and contributions to the *Omnium Botherum*, a quizzical serial, the object of which was local satire. A selection from his writings in prose and verse, including several of his orations, was published at Charleston in 1828, with a memoir of his life by the Rev. Samuel Gilman.

CRAG, in geology, sandy strata overlying the London clay, found particularly in the counties of Suffolk and Norfolk, England. Two divisions are recognized—the upper, called the red, and the lower, the coralline. The former is mostly made up of red ferruginous quartzose sands; the strata of the latter are more calcareous and marly, and more abound in masses of shells and corals, which are sometimes sufficiently compact for use as building stones. The formation is particularly interesting on account of the fossils with which it is filled, the great proportion of which are of species still living.

CRAIG, a S. W. co. of Va., formed since 1850 out of portions of Giles, Botetourt, and Roanoke counties, and named from Craig's creek, by the sources of which it is drained. The surface is mountainous, and the principal range of the Alleghanies extends along the N. W. border. The valleys are generally fertile, and produce corn, wheat, oats, and hay. Capital, New Castle. Value of real estate in 1856, $852,959.

CRAIK, George Lillie, an English author, born in Fifeshire in 1799. Having studied theology at the university of St. Andrew's, he went to London in 1824, and wrote for the society for the diffusion of useful knowledge the 2 volumes of the "Pursuit of Knowledge under Difficulties," published in Knight's library of "Entertaining Knowledge." He was a principal contributor to the "Penny Cyclopædia" in history and biography, and in 1839 became the editor of the "Pictorial History of England," and wrote those chapters on religion, government, laws, industry, and literature, which were afterward expanded into separate works in Knight's "Weekly Volume" as "Sketches of the History of Literature and Learning in England" (6 vols.), and the "History of British Commerce" (3 vols.). In the same series appeared "Spenser and his Poetry" in 1845, and "Bacon and his Philosophy" in 1846. He wrote in 1847 another volume of the "Pursuit of Knowledge under Difficulties," containing female examples only. He was appointed in 1849 professor of history and English literature in Queen's college, Belfast, and has since written "Romance of the Peerage" (4 vols.), "Outlines of the History of the English Language," the "English of Shakespeare," &c.

CRAIK, James, M.D., the family physician of Washington, born in Scotland in 1731, died in Fairfax co., Va., Feb. 6, 1814. He was with Washington in the expedition against the French and Indians in 1754, and the next year attended Braddock in his fatal campaign. In 1781 he was director of the hospital at Yorktown. To him we owe the anecdote respecting the dangers incurred by Washington, and his remarkable escape, at Braddock's defeat. Fifteen years afterward, while exploring wild lands in the western districts of Virginia, he encountered a party led by an aged Indian chief, who informed him, by an interpreter, that he had made a long journey to see Col. Washington, at whom in the battle of Monongahela he had fired his rifle 15 times, and ordered all his young men to do the same. In fact, Washington had 2 horses killed under him, and his coat was pierced with 4 bullets. After the revolution Craik settled near Mount Vernon, and continued to be the physician of Washington until his death.

CRAMER, John Anthony, a philologist, born in Switzerland in 1793, died at Brighton, England, Aug. 24, 1848. He passed the greater part of his life in England, having received his education at the university of Oxford, where he became principal of New Inn hall, and professor of modern history. He published many valuable works on philological subjects, beside descriptions of ancient Greece, Italy, and Asia Minor.

CRAMER, John Baptist, a musical artist and composer, born at Mannheim, Baden, in 1771, died in England, April 16, 1858, where he passed most of his life in great esteem as a composer and as a performer and teacher on the piano forte. His exercises and studies for the instrument are used in all parts of Europe and in America. His compositions are considered models of clear and simple construction, beauty, and grace.

CRANACH, or Kranach, Lucas, a German painter, whose family name was Sunder, born in Kronach, near Bamberg, in 1472, died in Wittenberg, Oct. 16, 1553. He was court painter to three electors of Saxony—Frederic the Wise, John the Steadfast, and Frederic the Magnanimous. He accompanied the first to the Holy Land in 1493, and shared the imprisonment to which the last was subjected after the battle of Mühlberg, in 1547. In 1533 he was appointed burgomaster of Wittenberg, and thenceforward enjoyed the intimate friendship of Luther, Melanchthon, and the other great reformers, whom he frequently introduced into his pictures. The school of Saxony, of which he was the head, is parallel to that of Albert Dürer, with whom he had much in common, although the earnestness and grandeur of the latter are replaced in Cranach by a graceful and almost childlike simplicity. Like Dürer, however, he was at times too much swayed by the fantastic element, then so prevalent in German art. His works are numerous in Germany, particularly in Saxony, and some good specimens are to be found in Florence. One of the most celebrated is an altarpiece at Weimar, representing in the middle the crucified Saviour, on one side of whom stand John the Baptist, the artist, and Luther; and on the other is the Redeemer, victorious over death and the devil. On the wings are portraits of the elector and his family. The picture has remarkable power in parts, and the portrait of Luther is singularly grand. In the wings of another altarpiece in the city church at Wittenberg, representing the last supper, he has introduced Luther, Melanchthon, and Bugenhagen, performing various religious duties. In mythological subjects he was not less successful, and his nude female figures have sometimes much grace and beauty of form. He also excelled in portraits, and has left accurate likenesses of some of the most notable men of the time. As an engraver he was inferior to Dürer, but his wood cuts are highly esteemed. Christian Schuchardt is the author of *Lucas Cranach des Älteren Leben und Werke* (Leipsic, 1851), and the editor and proprietor of an illustrated publication, with designs of Cranach's work, of which the 2d instalment (*Sechs Blätter mit sieben Nachbildungen von Werken Lucas Cranach d. Ä.*) appeared at Weimar in 1858.—His son, Lucas the younger, who officiated also as a burgomaster of Wittenberg, and who died in 1586, formed his style on that of his father and of Dürer, and attained great excellence as a painter.

CRANBERRY, the small, red, acid fruit of the *vaccinium macrocarpon*, and other shrubs of the same genus, distinguished by slender creeping stems, small evergreen leaves whitened beneath, and erect pedicels terminated by a pale rose-colored nodding flower, with a 4-parted corolla. The cranberry shrub grows best in lowlands, where the decay of organic matter furnishes the different organic acids. It is indigenous on both continents, wild in many parts of North and South America, in England and Ireland, in the marshy grounds of central and northern Europe, and on the wastes of Siberia. The American cranberry is larger than the English, and of richer flavor. The 3 principal varieties recognized in the markets are the cherry, bugle, and bell cranberries. The best of the cherry variety are very dark colored. Cape Cod is noted for its cranberry grounds; its climate and soil are both favorable to their growth, and the product is large and of the finest quality. The estimation in which this fruit is held both in Europe and America has caused many attempts, generally with little success on uplands, to produce it by artificial cultivation. Recently a wild upland cranberry has been discovered on the Neepegon coast of Lake Superior, where it flourishes on the poorest soils. The fruit is of a pale red color, smaller, softer, and sweeter than the lowland varieties, and well suited for jellies and preserves. The lowland berries succeed well on beach sand, or on soil composed of beach sand and peat. On heavy soils the vines

become luxuriant, but do not fruit well. A loamy soil is fitted for a cranberry ground by having beach sand applied to it; lowlands are improved for this purpose by being coated with sand. Taking off the sod and exposing the soil to a winter's frost, ameliorates its condition and rids it of weeds. Stagnant water kills the vines. If they are grown on swampy ground, its surface should be drained. The vines may be flooded in autumn and the water drawn off in the spring, which saves them from danger by frost, but makes them blossom later. If vines are taken up in the autumn to be planted again in spring, they should be protected in a cellar during the winter. A southerly aspect and shelter from cold winds are desirable. The vines should be chosen with great care, some of them being unfruitful; the best may be distinguished by the wiry texture of the wood, and the greenish brown color of the leaves. The poorer plants are more vigorous, brighter, greener, and have a more bushy foliage than the best. The vines should be planted in the spring, or in the autumn if the "patch" can be well flooded in winter. The transferring of the sods which bear the vines is going out of practice. A better method is to use cuttings from 4 to 6 inches long, the middle of which is covered in the soil, and the ends left projecting; or 2 or 3 cuttings may be planted together with a dibble. Vines have been cut into pieces 2 or 3 inches long by a common hay cutter, sown broadcast, and harrowed in. Propagation from seed is not to be depended on, the seed not germinating readily except in favorable localities; the seedlings are easily injured; there is much loss of time; and even in the third year little fruit is borne. The vines should be planted in rows 2 feet apart. The weeds should be kept down for 2 seasons, after which the vines will begin to take full possession of the soil. Cranberry vines are sometimes burned (but not when the ground is very dry) to destroy the worm. Flooding is also a remedy for this. The fruit ripens in the vicinity of New York about the middle of October. The persons who pick the berries are usually paid by the bushel. The vines should be picked clean. When gathered before they are ripe (as is sometimes done to save them from frost), or if the dew be on them, they do not keep well. The cranberry rake may sometimes be used to advantage; it is made of bent sheet iron, whose lower edge is a row of teeth shaped like the letter V; when drawn over the ground the plants escape, but the fruit is gathered. The berries may be rolled over an inclined plane to separate the good from the bad. Leaves, straws, prematurely ripe and diseased fruit, should be removed. Cranberries for Europe are packed in water in small kegs, and sometimes in sealed bottles filled with water. By the American aborigines poultices were prepared from cranberries to extract the venom from wounds made by poisoned arrows.

CRANCH, William, an American jurist, born in Weymouth, Mass., July 17, 1769, died in Washington, Sept. 1, 1855. He was the only son of the Hon. Richard Cranch of Quincy, Mass., who emigrated to the United States from Devonshire, England, in 1746. The father was for many years a judge of the court of common pleas in Massachusetts, and at one time a state senator. He was so well read and learned, though educated as a watchmaker, that the elder Adams said in 1815, in a letter to the Rev. Dr. Morse, that he was "a man who had studied divinity, and Jewish and Christian antiquities, more than any clergyman now existing in New England." From his mother, a woman of rare accomplishments and virtues, William Cranch received the beginning of his education, including instruction in the elements of algebra and Latin. He was graduated at Harvard college in 1787, commenced the study of the law, and was admitted to the bar in July, 1790. After practising for 3 years in the courts of Massachusetts and New Hampshire, he removed in 1794 to the district of Columbia, where he passed the remainder of his life. In 1800 he was appointed one of the commissioners of public buildings, and on Feb. 27, 1801, was nominated to the senate by President Adams, and by that body confirmed, as one of the assistant judges of the U. S. circuit court for the district of Columbia, Gov. Thomas Johnson of Maryland and James Marshall (brother of Chief Justice Marshall) sitting with him as associate judges. In 1805, upon the resignation of Chief Justice Kiety, who had been made chancellor of Maryland, Judge Cranch received the appointment of chief justice of the court from President Jefferson, and in virtue of that office became sole judge of the district court of the United States for the district of Columbia; a court of the same jurisdiction as that of the United States district courts in other parts of the country. These honorable positions Judge Cranch held until Sept. 1, 1855, the day of his death. For 55 years he was judge of a U. S. court, for more than 50 years chief justice; and in all this period of time, notwithstanding the facilities of appeal to the supreme court of the United States, and, in the district of Columbia, upon judgments of a much smaller amount than those rendered in the U. S. circuit and district courts in the states, only 2 of his own decisions were overruled or sent back for amendment by the highest court in the country. In all the courts of the country and to all the members of the bar Judge Cranch is well known as the reporter of the decisions of the U. S. supreme court. In this office he was preceded by Mr. Dallas, and succeeded by Mr. Peters. He also made full and accurate reports of the cases decided in the circuit court of the district of Columbia from 1801 to 1841, which were published in 6 large volumes a few years before his death. In conformity with an act of congress he also prepared a code of laws for the district of Columbia, but this code, like that prepared by Philip Doddridge, M. C. from Virginia, some years later, was neglected by congress. As a judge he was always fearless, independent, wise.

and just. His proximity to the federal authorities brought him more than once into conflict with the executive department, and upon questions involving the rights and integrity of the judicial service. In all such conflicts he proved an able and upright judge. His legal acquirements were extraordinary, and he studied his cases with a patience and research that never grew weary. Among the last services imposed upon him by congress, was the final hearing of patent causes after an appeal from the commissioner of patents. He was alike familiar with the modern lights of jurisprudence and with all the black-letter authorities. Long after he had reached the age of threescore and ten years he still gave to study 12, 14, and even 16 hours a day. He could not only toil like a very Hercules in his profession, but he loved that profession and all its labors with his whole heart. He also had a fondness for art and for music, and with the latter he had a practical acquaintance which he enjoyed through life, especially sacred music, with all the earnestness of youthful enthusiasm. He was eminently a religious man, an example of Christian charity and all the amenities of life. During his long career he possessed the respect of all who knew his abilities and services, and the confidence of all who knew him as a man. His habits of life were singularly simple, his manners modest and reserved, and his character child-like and confiding. His wife, Nancy Greenleaf, of Boston, died 12 years before him. They had 13 children, of whom the sons were liberally educated, while the daughters enjoyed every advantage of instruction which the federal capital could afford, all upon the father's salary of $2,500 and $2,700 a year, out of which they also were able to live respectably and bestow something in charity to the poor.

—Christopher Pearse, son of the preceding, an American artist and poet, born at Alexandria, D. C., March 8, 1813. He was graduated at Columbian college, in Washington, in 1831, studied for 3 years in the divinity school of Harvard university, became a licentiate, but gradually withdrew from the clerical office, and in 1842 determined to devote himself to landscape painting. He resided in New York in the practice of his art from that time till 1847, when he visited Italy for 2 years. He went again to Europe in 1853, and has since then lived in Paris; and his productions have given him a prominent position as an artist. Mr. Cranch was one of the contributors to the "Dial," edited by R. W. Emerson and others, and some of his best poems were published in that periodical. In 1854 a volume of his poems appeared at Philadelphia. His latest publications are two stories, entitled the "Last of the Huggermuggers" (Boston, 1856), and "Kobboltozo" (1857), the latter of which is a sequel to the former. He continues to write occasionally for various American journals and magazines.

CRANE, a wading bird of the order *grallæ*, family *ardeidæ*, and subfamily *gruinæ;* under this subfamily are included the genera *grus*, *scops*, and *balearica*. The genus *grus*, which includes the typical cranes, has the bill longer than the head, straight, sharp-pointed, compressed on the sides, and slightly curved at the tip; the wings are long, the tertials lengthened and pendent; tail short; tarsi very long and slender, covered with transverse scales; toes rather short, the outer united at the base to the middle one, the lateral ones equal; hind toe short and elevated; claws short and strong. The cranes are large birds, frequenting marshes, muddy flats, cultivated and open plains, migrating to warm climates in winter, and returning to the north to breed. They fly usually at night in large flocks, following a leader in 2 diverging lines, at a great elevation, and sometimes uttering loud cries. Their food consists of reptiles, fish, mice, and other small animals, insects, seeds, roots, and grain. The common crane of Europe is *G. cinerea* (Bechst.). The American crane (*G. Americana*, Linn.) is a good example of the genus. It has the bill dusky, and yellow toward the base; the head small, neck very long, body rather slender, tibia bare to a large extent; the bare parts on the top and sides of the head carmine, with small black hairs; feet black; plumage pure white except the primaries and their coverts, which are brownish black. The length to the end of the tail is 54 inches, and to the end of claws 65; extent of wings 92, bill 5½, tarsus about 11 inches. Young birds are of bluish gray color, with the feathers tipped and margined with yellowish brown, and the abdomen grayish blue; in this state the bird was described as *G. Canadensis*. This species, called whooping crane from the loud noise it makes, is by some considered specifically distinct from the true *G. Canadensis* (Linn.), to which the name of sand-hill crane has been given. The cranes are found in the western and southern states from the middle of October until about the middle of April, when they retire to the north. They are very shy, and difficult to approach from the acuteness of their sight and hearing; when wounded, they should be approached with caution, to avoid the blows of their sharp and powerful bills. They roost either on the ground or on high trees, according to circumstances. The nests are made among the high grass, of coarse materials, flat, about 18 inches in diameter, but little elevated above the surface; the eggs are 2 in number, bluish white, and are sat upon by both birds. They become gentle in captivity, feeding on vegetable substances. The genus *scops* embraces the Numidian crane (*S. virgo*, Linn.), ash-colored, with a black neck, and 2 white tufts of elongated slender feathers covering the ear; this is often kept in captivity, and is quite gentle. The genus *balearica*, peculiar to Africa and the islands of the Mediterranean, has the bill shorter than the head, thick and strong; the cheeks are naked, and the base of the bill and the throat beneath are wattled. The crowned crane (*B. pavonina*, Linn.) is a slender, graceful bird, about 4 feet high, ash-colored, with a black

belly, white wings, and fulvous rump; the naked cheeks are bright rose color, and the hind head is crowned with a tuft of yellow feathers or hairs, resembling the flower stems of broom corn, which may be extended at pleasure; it is also often kept in captivity for its beauty and docility; its voice is remarkably shrill. In its wild state it feeds on fish.

CRANE, a machine for raising heavy weights, and moving them short distances. In its simplest form it consists of an upright post with a horizontal beam called a jib, framed in or near its top, and braced by a stick called a stay, which is framed in the post and the jib. It is held upright, with freedom to turn round, by a pin in each end of the post, one working upon a solid support below, and the other in a beam above; or the upper support may be in a collar encircling the post and secured to a stationary object, as a wall or another post. A pulley is set in or suspended from the further extremity of the jib, by which the weight is taken up, the fall of the tackle passing around the drum of a winch attached to the lower end of the post. Such cranes are employed in founderies and upon piers, where large blocks of stone or other heavy materials are shipped or unshipped, and are set upon some barges to be always at hand for moving their heavy freight. Their construction is, however, generally a modification of the simple form described. The horizontal jib has often a narrow rail upon its top, upon which a flanged wheel traverses, supporting the pulley. This admits of the weight being brought nearer to the post, so that it may be placed upon any part of the circular area included in the sweep of the jib. Cranes are often made with the jib set at an inclination of 45° or thereabouts, and stepped at its lower end in a framework of iron, which carries also the winch, and may be turned around the post which it encircles. In these the foot of the post is set strongly in mason work, and no support is required to steady it at top. The jib is kept up by tension bars placed above it and extending horizontally from its extreme end to the top of the post. A convenient crane for laying small stone, employed in constructing the dry dock at Brooklyn, was made with a boom 30 feet long, working upon a horizontal iron bolt attached to the frame of the winch. The working part of the winch, its pinion with a crank at each end of the axle, and the wheel driven by the pinion, with the barrel upon its axis, were set upon the side of the mast opposite to the boom, and the fall passed up to the top 40 feet from the ground, and thence over the end of the boom to the pulleys suspended below it. The mast worked upon a pivot stepped upon a stone foundation, and its upper end was stayed by guys. The boom could be lowered or raised by a pulley passing from its extremity to the top of the mast, the fall coming down and made fast at its foot. In some cranes, made to lift very heavy weights, the foot of the jib, instead of resting upon the crane post, is set against a circular rail let into the masonry, thus relieving the post of a great portion of the strain. Cast iron has been much employed for some years past, instead of timber, for the construction of cranes; and Mr. Fairbairn, of England, has introduced the use of plates of wrought iron, riveted together and arranged in tubular form, on the principle adopted in the building of the Britannia tubular bridge. His crane, designed to raise 12 tons, has been tested with 20, and is supposed capable of bearing 60. It sweeps a circle of 53 feet radius. The under side of the jib is of cellular construction to resist pressure, and there are long plates, and T iron on the upper side to resist tension. The jib being curved like the neck of a crane, allows a large boiler or other article to be raised to the top.—The power employed to work cranes is usually that of men turning the winch. In some situations they are conveniently connected with machinery running by steam or other power, and their movements are controlled by a lever brought to bear with as much friction as may be required upon the barrel of the winch by a rope held in the hand of the man who manages the machine. They have also been made to work by the pressure of a column of water upon a movable piston, a valve in the supply pipe being used to control the movement. Steam, also, has been applied to work a small engine connected directly with the barrel of the winch.—The most powerful of all cranes ever built are those contrived by Mr. Albert Bishop of New York, and generally known as Bishop's boom derrick. Derrick is a name commonly applied to cranes used on shipboard. Several of these have been in use since the year 1853 in New York harbor; the stationary ones are for moving boilers and heavy machinery in or out of steamships. One was built upon a scow, that admits of its being floated about wherever required for raising sunken vessels. On Sept. 27, 1858, the first one of the kind built in England was launched in Bow creek, London, which far exceeds in capacity those made in the United States. It is built upon a huge iron hull of 5,000 tons measurement, 257 feet long, and 90 feet wide. This is stayed by trusses of wrought iron and tie rods, that give it greater strength than that of any other vessel ever put together, not excepting the Great Eastern. The propelling power is furnished by 2 pairs of oscillating engines of 160 horse power each, with Barran's patent cup surface boilers; and 2 other oscillating engines, of 30 nominal horse power, are provided for working 10 sets of crabs, independently of each other. Their combined hoisting power is rated at 1,000 tons clear of the water; and the load can be swung upon an arc the radius of which is 60 feet, and moved in or out upon this radius. The post is a stand like a tripod, except that it has 4 legs. These are of wrought iron, strongly braced with iron, and their cap is 80 feet above the deck. This is a huge iron saucer containing iron balls, upon which the cross or yard called the boom is supported, and

rolls around; this, too, is of wrought iron, 120 feet long and weighing 80 tons. Upon its centre stands a wrought-iron cylinder called the king post, 50 feet high, 7 feet in circumference, and weighing 60 tons. From the top of this 10 tension braces of iron rods pass down on one side to the boom, along which they are arranged like the supporting wires of a suspension bridge, and a smaller number pass to the end of the boom on the other side; from this end powerful rods are let fall to the deck, where they are secured to a circular railway, that admits of their moving as the boom is swung round. Along the suspension arm of the boom are placed 10 heavy pulleys, the falls of which pass down to the crabs or winches in the base of the stand. The tackles of these concentrating below in one resemble the arrangement of the web of the spider, where numerous strands are brought to combine their strength at one point. These tackles connect with the great chains employed in lifting sunken ships. The weight of iron in the hull is 750 tons, and in the derrick itself about 250 tons, making 1,000 tons, independently of the weight of all the machinery. The total cost was £45,000. The machine is intended to go out to sea, and to be employed near Liverpool as well as London, until others are constructed for each place. The paddles for propelling the vessel are very small, arranged upon an endless chain, and are compared to the legs of a caterpillar. In 1857 there were on the English coast 1,141 wrecks reported, and there is no doubt a very large proportion of these vessels could have been raised, if such machines had been available.

CRANE, William M., a commodore in the U. S. navy, born at Elizabethtown, N. J., Feb. 1, 1776, died in Washington, March 18, 1846. He was the son of Gen. William Crane, who served as colonel in the revolutionary army. He entered the navy as midshipman in May, 1799; was made a lieutenant in July, 1803; served before Tripoli under Commodore Edward Preble, and was present at all the attacks made upon the city. He was serving on board the Chesapeake at the time of her action with the Leopard. At the commencement of the war with England he was appointed to the command of the brig Nautilus of 14 guns, in which he was unfortunately captured in July, 1812, by a British squadron, soon after sailing from New York. On his exchange he was ordered to the lakes, where, in command of the Madison and Pike, in the squadron of Com. Chauncey, he served with distinction for the remainder of the war. From 1815 until his death, Com. Crane was very constantly employed in important service. During one cruise of over 4 years in the Mediterranean, he commanded successively the Independence ship of the line, the Erie sloop, and the frigates Constellation and United States. In 1827 he was appointed to command the American squadron in that sea, the Delaware ship of the line bearing his flag. While on this service he acted as joint commissioner with Mr. Offley, U. S. consul at Smyrna, to open negotiations with the Ottoman government, preliminary to a commercial treaty, which was concluded soon afterward. In 1841 he was appointed navy commissioner, and in 1842, when the navy department was reorganized, was made chief of the bureau of ordnance and hydrography, which he administered until near his death.

CRANK, an axle bent twice at right angles, or it may be 4 times, so as to return upon its original line, in which case the axle may be supported on each side the elbow. When it is made to revolve, a rod playing loosely upon the elbow will be carried forward and back; thus an alternating motion is obtained from a rotary; and on the same plan an alternating motion may be converted into a rotary motion. Watt applied it to the steam engine, taking the idea from the crank of the knife-grinder's machine, by which the alternating motion given to the treadle with the foot causes the wheel to rotate. It has continued in one form or another to be indispensable in almost every kind of steam engine.

CRANMER, Thomas, the first Protestant archbishop of Canterbury, born at Aslacton, Nottinghamshire, July 2, 1489, died March 21, 1556. His family is said to have been ancient, though by some authorities his father is called a yeoman. Having acquired the rudiments of knowledge at Aslacton school, he was sent at the age of 14 to Jesus college, Cambridge, where he remained 16 years. He was not only an accomplished scholar, but versed in pursuits that belong especially to active men of the world; and he lost his fellowship through marriage. His wife dying soon, he turned his attention to the church, and in 1523 was made doctor in divinity, appointed theological lecturer of Jesus college, and examiner of candidates for holy orders. While married, he had been common lecturer of Magdalen (then Buckingham) college. When on a visit to Mr. Cressy, at Waltham, 1529, he met the secretary and almoner of Henry VIII., who pressed him to give his opinion on the question of the king's divorce, Henry being anxious to get rid of Catharine of Aragon, in order that he might wed Anne Boleyn. Cranmer said that the opinion of the learned men of Europe should be taken on the question whether, according to the canon law and the Bible, a man could marry his brother's widow; and that the pope could not resist that opinion if it should be pronounced in favor of the king, while if it were against him the king would himself have to submit. This was told to Henry, who was struck by it, and he ordered Cranmer to come to court. The personal interview that followed was very satisfactory to Henry, who required Cranmer to reduce to writing what he had to say in favor of the divorce, made him a royal chaplain, and put him in the household of Anne Boleyn's father. Cranmer completed his work on the divorce, bringing his chief arguments against that papal dispensing power under which Henry had mar-

ried his brother Arthur's widow, to the royal satisfaction; and then was appointed to superintend the execution of the plan he had suggested. He began at Cambridge, where he encountered much opposition. Oxford was more pliant. On the continent he succeeded better, and many learned and pious men gave such judgments as were pleasing to Henry and his agent. He was also appointed to accompany Lord Wiltshire, Anne Boleyn's father, and others, on a mission to Bologna (1530), where the emperor then was, and to the pope. Clement VII. had for several months previously resisted all solicitations to pronounce judgment on the cause, but at length had been induced by the influence of Charles V. to sign a brief forbidding Henry to marry before the publication of his sentence. On the arrival of the ambassadors, the operation of the brief was suspended; the pope received them cordially, conferred an office on Cranmer, and promised to do whatever his conscience would permit in favor of Henry. The emperor took a more decided stand against the demands of the embassy, and was gracious only to Cranmer, who was really the most efficient member of the divorce party. When Lord Wiltshire returned home, Cranmer went to Germany, for the purpose of working on the minds of the Lutheran clergy, and to perform certain diplomatic duties. He was not successful, but the Lutherans converted him. Though yet a Catholic clergyman, nominally, he married the niece of the celebrated Osiander of Nuremberg, an excellent woman. Love had probably much effect on his mind, and tended to change his religious belief. He was made archbishop of Canterbury in 1533, soon after his return to England. Undoubtedly he desired not this promotion, which exposed him to great danger, and the *nolo episcopari* in his case meant something; but Henry was not the sovereign to digest a refusal, and Cranmer, before swearing obedience to the pope, made a private protest substantially declaring he did not consider the oath binding. He immediately proceeded with the divorce, and declared the marriage between Henry and Catharine null and void from the beginning. The queen refused to appear in his court. It is not true that he married Henry and Anne, as he was not even present at the ceremony, and knew not of its occurrence until a fortnight had elapsed; but he delivered the crown and sceptre to Anne at her coronation. When the pope had excommunicated Henry, Cranmer became an active agent in the reformation, and urged forward measures calculated to make the breach complete, his principles and his fears alike dictating that course. Yet he was always opposed to cruelty, and, provided his own safety was assured, would have been content that all others should live and prosper. He tried hard to save More and Fisher. His personal enemies he forgave with a readiness that somewhat lessens admiration, because it suggests that he had small sense of either favors or injuries. When Anne Boleyn was arrested, he was ordered to go to his episcopal palace, and there to remain, an act intended to frighten him into taking some part in the queen's degradation and murder. The king and his instruments knew his timid nature, and that his high office and pure personal character would help gloss over a foul transaction. At first, the primate was disposed to show some spirit, and he wrote a letter to Henry which was favorable to Anne, though not strikingly so; but before the letter was sent, he was summoned to the star chamber, where he had an interview with some of the high officers of the crown, and others, and their communications caused him to add a postscript to the effect that he was persuaded of the queen's guilt. Mr. Froude, who would, to borrow a saying of that age, find Abel guilty of the murder of Cain, in his zeal to show that whatever Henry VIII. did was of necessity right, draws from this postscript the utterly illogical inference that the evidence against Anne placed before Cranmer was conclusive; whereas it is probable the primate was frightened by the persons who had been appointed to work upon his timorous nature. His feelings were ever good, but he had no courage. After the scandalous trial and condemnation of Anne, she was taken to Lambeth, where Cranmer, sitting in judgment, pronounced her marriage null and void from the first (1536). The archbishop had his share in the persecutions that were carried on by Henry, and in some instances took part in sending to death persons who believed what soon afterward he came to believe himself, if he did not believe it at the time he condemned them. When Cromwell suspended the power of all the prelates and ordinaries in the kingdom, in virtue of his power as vicar-general, and because of the general visitation that was to be made, Cranmer set the example of submission, and placed the church at the feet of the king, having previously contended that the king alone had the power of appointing spiritual officers. He seems to have been ready to go as far as Erastus himself in maintaining the authority of the civil power. The suppression of the monasteries was supported by him, but he was desirous that some of the property seized should be used for the purposes of religion and education, instead of being given to mercenary courtiers. He took an active and prominent part in placing the Bible in the hands of the English people in their native tongue. In 1534 he carried through the convocation a resolution that the Bible should be translated, and the holy volume appeared in 1540, Cranmer's portrait being conspicuous in the frontispiece. Through his influence the creed, the Lord's prayer, and the commandments were taught in English. Yet the Protestant doctrines were far from being established in England, and in 1539 the famous "six articles" were adopted, in opposition to Cranmer's advice and exertions. They were Catholic in character, and

one of them bore hard upon Cranmer. He was married, and the 3d declared that it was not permitted to priests to marry and have wives after ordination. On this point Cranmer contended strongly, and Henry, who liked him as well as he was capable of liking any one, bore with his opposition, but would not abandon his purpose. He then submitted, and sent his wife and children to Germany, where they remained until Henry's death. After this, Cranmer was less prominent at court than he had been, and though he continued to have the king's favor, he was once on the eve of being arrested. He supported the project of marrying Henry to Anne of Cleves, received that lady after her arrival in England, and presided in convocation when that body declared the marriage dissolved (1540). He interceded for Cromwell, but ineffectually. It was by him that Henry was informed of the alleged criminality of his 5th queen, Catharine Howard (1541); and as she belonged to, and was in the hands of, the Catholic party, which aimed at the primate's destruction, it is not uncharitable to suppose that he was a willing informer. It shows the estimation in which he was held by the king, that he was selected by him for consoler when he was dying, and that Henry's last earthly act was to wring his hand as evidence that he put his trust in God through the Saviour. By the royal will, Cranmer was appointed a member of the council of regency that was to rule during the minority of Edward VI., who was but 9 years old (1547.) During the "boy king's" life, Cranmer's influence was great, and was directed to the establishment of that ecclesiastical polity which has ever since endured in England, with the brief interval of Mary's reign, and which now, after the lapse of 3 centuries, affords no indications of decay. He was the founder of the church of England, and of most that is peculiar in the nature of that venerable institution. Most of his actions of that time will bear criticism, but not all. Against the prohibition of the canon law he had a prominent part in the legal murder of Lord Seymour of Sudely, at the instigation of that lord's brother, the protector Somerset. In the harsh treatment of the Catholic prelates he was the principal agent. When it was found necessary to overcome Edward's natural repugnance to the burning of "heretics," Cranmer was employed to convince him that such conduct was proper. He sentenced persons to the stake for the very opposite belief to that for which he had taken part in condemning others in the reign of Henry; and when he was reminded of his horrible inconsistency by one of his victims, the effect was to irritate him against her. This was worse than his assisting at Henry's condemnation of Lambert, which is considered one of the worst deeds of that iron age. Cranmer was an adherent of Somerset in the contests that divided Edward's court, and by the protector he was supported in his ecclesiastical reforms. When Edward resolved to leave the crown to Jane Grey, Cranmer was reluctantly induced to sanction the act, which was as absurd as it was illegal. He adhered faithfully to her, and fell with her. He had nothing to hope from Mary, and his last official act was to serve at the funeral of Edward. The next day, Aug. 9, 1553, he was ordered to confine himself to his palace at Lambeth, and to furnish an inventory of his movables. He bore himself meekly, but he denied, in language worthy of Latimer, that he had consented to the performance of the mass in Canterbury cathedral. For this he was summoned before the council, and on the 13th of October was committed to the tower, on the charges of treason and sedition. Having been attainted by parliament, and it being resolved to proceed against him for heresy alone, he was sent down to Oxford with Latimer and Ridley, to go through the form of disputing with Catholics on the contested points of religion. All were condemned, of course, though the Protestants were not so much as heard. To the demand of the commissioners before whom they were then taken, whether they would return to the old faith, they answered in the negative. Cranmer was then cited to appear at Rome within 80 days, and as he could not do so, he was condemned as contumacious. At first he was firm, but the terror caused by that form of death to which he had sentenced others, and by which Ridley and Latimer had suffered so much, overcame him. He faltered, and then recanted, but not until, in a moment of courage, he had written to the queen in behalf of Protestantism. He signed 6 recantations, and so acted as to show he was the victim of abject fear. But all this was of no avail. Mary hated him because of what he had done against her mother and herself, and it must be allowed that her conduct was natural. Gardiner and Bonner hated him because of the personal oppression they had suffered at his hands. Both queen and bishops were resolved upon his degradation, and equally that it should not save his life. He was ordered to prepare for death. He then was guilty of the falsehood of saying that his recantations had been freely made, and he begged for a short delay in order to give further proof of his repentance. This granted, he made his last confession, in which he declared that he had been the greatest of persecutors, and compared himself to the penitent thief; nor was there any abjectness to which terror is capable of driving the coward, of which he was not guilty. He concluded with begging pardon of his oppressors, humiliating himself before the queen. Had Mary and her associates been equal to the enjoyment of refined vengeance, they would have granted him life and immediate liberty; but they determined that he should know he had degraded himself in vain, and so taste a double portion of the bitterness of death. On March 21, 1555, much to his astonishment, he was directed to prepare himself for the stake. A paper consisting of an abstract of his recan-

tations was given him, which he was to read at the stake. He transcribed and signed it, and kept a copy, which he altered, and made a disavowal of all his recantations. After listening to a sermon in the church of St. Mary, he boldly spoke out, and declared himself a Protestant, saying he died in his former faith, believing neither in the papal supremacy nor transubstantiation. He apologized for his recantations, and declared that the hand which had signed them should first burn. He was burned opposite Baliol college, and when the flames were rising around him he thrust his right hand into them, and is said to have held it there until it was consumed, crying aloud: "This hand hath offended—this unworthy right hand." He showed no unmanly weakness in that terrible hour, repeating, with his eyes cast upward, the words: "Lord Jesus, receive my spirit!" and then expired.—The principal authorities for the career of Cranmer are Strype's "Memorials," the "Lives" of him by Todd and Le Bas, the historical works of Burnet, Hallam, Turner, Lingard, Froude, and Macaulay. Mr. Froude appears to doubt if he suggested the plan of proceeding with respect to the divorce question in which his career as a courtier and a statesman is commonly supposed to have originated; and Lord Macaulay has spoken of him as severely as he speaks of Marlborough. The "Life and Times of Thomas Cranmer," published at Boston in 1841, is a valuable American contribution to the history of the founder of the English church.

CRANTARA (Gaelic, *crean tarigh*, the cross of shame), a military signal employed by the Scottish highland chiefs. It was a firebrand or wooden cross, which, after being dipped in the blood of a goat, was sent by a swift-footed herald to the nearest hamlet, where he delivered it without uttering a word, save the name of the place of rendezvous. The fleetest runner of that hamlet was instantly despatched with the signal to the next, whence it was borne to a third, and so on, till every village within the chief's domain had received the summons. The last time the crantara was circulated in Scotland was during the rebellion of 1745.

CRANTOR OF SOLI, an academic philosopher, and the 1st commentator on Plato, flourished at the close of the 3d century B. C. He studied under Xenocrates and Polemo, and was the author of several works, all of which have perished. Most of his writings related to ethical or metaphysical subjects. One of his most celebrated productions was a treatise on "Grief," of which Cicero made liberal use in his "Tusculan Questions," and in the *Consolatio*, composed by him on the death of his daughter.

CRANWORTH, Robert Monsey Rolfe, baron, late lord high chancellor of England, born at Cranworth in Norfolk, Dec. 18, 1790. He was educated at Cambridge university, and in 1816 was called to the bar, where he soon acquired a lucrative practice. In 1834 he was appointed solicitor-general, and again in April, 1835, retaining the office until 1839, when he was made one of the barons of the exchequer. In Dec. 1850, he was appointed vice-chancellor and raised to the peerage as Baron Cranworth. In Dec. 1852, he was appointed lord high chancellor by Lord Aberdeen, and held the great seal until the formation of the Derby ministry in 1858, when he retired from office.

CRANZ, David, a German missionary and historian, born in Pomerania in 1723, died at Gnadenfrei, in Silesia, June 6, 1777. He became in 1747 secretary to Count Zinzendorf, entered a community of Moravians, went in 1761 as missionary to Greenland, and after his return in 1766 was successively pastor at Rixdorf and at Gnadenfrei. He wrote a *Historie von Grönland* (Barby, 1765; 2d edition, with additions, in 1770), and a *Brüder-Historie*, or history of the Moravian Brethren, published at Barby in 1772, and continued by Hegner, 1791–1816.

CRAPE, a delicate transparent fabric, made of raw silk with the gloss removed. Crapes are either crisped or smooth. The crisped which are double require that the silk should be spun harder than for the single, as the degree of twist regulates the crisping. All crapes are woven and dyed with the silk in the raw state. In finishing, they are stiffened with gum water. Crapes of superior quality are manufactured at Lyons in France, and at Yarmouth and Norwich in England. Bologna, however, claims the invention.

CRAPELET. I. Charles, a French printer, born at Bourmont, Nov. 13, 1762, died in Paris, Oct. 19, 1809. He came to Paris at the time when great attention was beginning to be paid to the improvement of typography in finish and elegance. He practised his profession there for 20 years, and his editions are highly esteemed for their correctness. The most remarkable productions of his press are 12 copies, in letters of gold, of the *Oiseaux dorés* of Audibert. II. Georges Adrien, a printer and author, son of the preceding, born in Paris, June 13, 1789, died at Nizza, Dec. 11, 1842. He maintained the reputation of his father, and the works which he published are esteemed for correctness and beauty of execution. Among them there are editions of La Fontaine, of Montesquieu, Voltaire, Rousseau, and Sismondi's *Histoire des Français*. The idea of publishing a collection under the title of *Anciens monuments de l'histoire de la langue Française* originated with him. He wrote an account of the progress of the art of printing in France and Italy in the 16th century, and its influence upon literature (8vo. 1836), and was the author of "Souvenirs of London," and of a history and description of that city, beside several translations from the English.

CRASHAW, Richard, an English poet and divine, born in London, died in Loretto about 1650. The son of an Anglican clergyman, he was educated at the Charterhouse, London, till in 1632 he went to Pembroke hall, Cambridge,

where he was graduated in 1633, and became fellow of Peterhouse in 1637. In 1634 he published anonymously at Cambridge a volume of Latin poems under the title of *Epigrammata Sacra*, in which occurs the celebrated verse on the miracle at Cana:

Nympha pudica Deum vidit et erubuit.
(The modest water saw its God and blushed.)

The English verse (which often has "conscious" instead of "modest") has been attributed also to Milton and Dryden. Crashaw was afterward admitted to holy orders, and lived for several years in St. Mary's church, near his college, occupied with religious offices, and with composing devotional poems. He is spoken of as now "offering, like a primitive saint, more prayers by night than others usually offer in the day." At this period he was noted as an eloquent and powerful preacher. In 1644, for refusing to accept the covenant, the parliamentary army ejected him from his fellowship, and he removed to Paris, where he became a Roman Catholic. Cowley sought him there in 1646, and finding him in great poverty, obtained in his behalf the favor of Henrietta Maria, queen of Charles I. of England, who gave him letters of recommendation to dignitaries of the church in Italy. He went to Rome, and became successively secretary to one of the cardinals, and a canon in the church of Loretto. His English poems, entitled "Steps to the Temple, Sacred Poems, with other Delights of the Muses," were published in London in 1646 (2d edition in 1648). A posthumous volume appeared at Paris in 1652 under the title *Carmen Deo nostro*. Several of his pieces are admirable translations from Latin and Italian. He was an admirer of mystical writings, especially of those of St Theresa, and his poems are remarkable for the beauty, force, and passion with which they treat religious subjects. He has also left some miscellaneous poems of remarkable beauty. One of the finest of Cowley's compositions is a monody on his death. Editions of his collected works appeared in 1670 and 1785. His complete works, edited by W. B. Turnbull, were published in London in 1858.

CRASSUS. I. Lucius Licinius, celebrated as the greatest orator of his age, born in 140 B. C., died in 91. When 21 years old he distinguished himself by the prosecution of C. Carbo. As consul of the year 95, with Quintus Mucius Scævola, he contributed to the enacting of a law expelling all allies, not citizens of Rome, from the city, which rigorous measure was one of the sources of the social war. Sent as proconsul to the province of Gaul, his administration was distinguished for strict justice. While censor in 92, he caused the schools of the Latin rhetoricians to be closed, as pernicious to the morals of the people. Shortly before his death he vehemently defended the laws proposed by the tribune Marcus Livius Drusus against L. M. Philippus, one of the consuls. Crassus was fond of elegance and luxury; his house on the Palatine hill was remarkable for its splendor, and adorned with works of art. In Cicero's *De Oratore* he figures as one of the speakers, and is supposed to express the opinions of the author. II. Marcus Licinius, one of the first triumvirs, killed near Carrhæ in Mesopotamia, 53 B. C. He was the descendant of a family several members of which had attained high honors in the republic, and borne the surname of *Dives* (rich). His father, who was consul and censor, was in the civil war a zealous partisan of Sylla, and died by his own hand after the victorious return of Marius and Cinna in 87. Young Crassus escaped to Spain, whence he went to Africa after the death of Cinna, and from there to Italy (83) to fight against the Marian party. Enriched with the spoils of the defeated and proscribed party, his avaricious and speculative spirit found ample means to augment his wealth to an immense amount by purchases at auction, by farming, mining, and letting out houses and slaves, and thus fully to deserve the family surname. His riches and hospitality gave him influence and favor with the people, which paved his way to civil and military distinctions, though he was possessed of no remarkable talents. In 71 he was prætor, and received the command against the revolted slaves under Spartacus; he rapidly raised 6 legions, and defeated Spartacus in a bloody battle on the river Silarus, in which that terrible enemy of Rome was slain. Crassus received an ovation, being crowned, as conqueror of slaves, with a wreath of laurel instead of myrtle, and was elected, together with Pompey, consul of the following year. Rivalling the influence of his great colleague, he bribed the people of Rome by extraordinary banquets and distributions of corn, but was finally reconciled with his rival, and united with him and Cæsar in forming the first triumvirate (60 B. C.). Cæsar, who received the province of Gaul, a field for vast conquests, lulled by some minor undertakings the attention of his colleagues, who supported him by the influence of their fame and wealth. The compact was renewed, and Crassus was again elected with Pompey consul for the year 55. According to the new terms, Cæsar was to continue his government in Gaul, Pompey received Spain, and Crassus Syria. Lavish preparations betrayed his intention of entering upon a great expedition against the Parthians, which promised to become a source of boundless conquests and riches. In anticipation of these, his joy is said to have been childish; and the opposition of the tribunes, as well as various omens which alarmed the people, could not deter him from his undertaking. He marched through Macedonia and Thrace to Asia, crossed the Euphrates (54 B. C.), ravaged Mesopotamia, but returned to Syria, where he spent the winter, before starting on a new campaign in 53. He recrossed the Euphrates, following the false advice of an Arabian chief, and was attacked by Surena, the general of Orodes, king of the Parthians, near Carrhæ, supposed to be the biblical Haran. The Romans were defeated with immense slaughter. Crassus retreated to the town, but was compelled by a

mutiny of the soldiers to accept the invitation of the enemy to a conference, in which he was killed. The circumstances of this event are variously related. His head was sent to the Parthian king, who is said to have poured into his mouth melted gold, saying: "Now be satiated with what thou covetedst through life."

CRATER (Gr. κρατηρ, a bowl), the opening on the tops or sides of volcanic mountains, through which the lava and ashes are ejected. The crater of Etna, like many of the most ancient volcanoes, does not retain the bowl-like shape to which the name owes its origin; that of Vesuvius, however, preserves its primitive form.

CRATERUS, a general of Alexander the Great, received after the death of that conqueror, in 323 B. C., together with Antipater, the government of Macedonia and Greece. He assisted Antipater in the Lamian war, and also against the Ætolians and Perdiccas, and fell in a battle against Eumenes (321).

CRATES. I. A comic poet of Athens, flourished about 450 B. C., and was contemporary with Cratinus. Eminent as an actor, he often performed the principal parts in the plays of Cratinus. As a comic poet he was the first Athenian who ventured to follow the example of Epicharmus so far as to bring drunken characters on the stage. Aristotle in his "Poetics" bears testimony to the excellence of his works. Little, however, is really known of them. Meineke, who has made a careful analysis of the statements of ancient writers on the subject, gives the titles of 14 which were ascribed to him. Fragments of 8 of these are still extant. II. A Cynic philosopher, born at Thebes, early removed to Athens, where he became the pupil of Diogenes, and afterward one of the most eminent in that school of philosophers. He flourished about 320 B. C. According to Diogenes Laertius, he lived a Cynic of the straitest sort. Fearing that the quiet of philosophical pursuits would be disturbed by the cares of wealth, of which he had an abundance, he is said to have thrown his money into the sea; or, according to another account, to have placed it in the hands of a banker, with the condition that if his sons should have the misfortune to be fools, they should inherit the property, and that otherwise it should be distributed to the poor. "For," said Crates, "if they are philosophers, they will not need it." III. An Athenian philosopher, the pupil and friend of Polemo, and his successor in the chair of the academy, flourished in the first half of the 3d century B. C. He contributed little to the progress of philosophical investigation, and is known mainly as the instructor of Arcesilaus and others. IV. An eminent Greek grammarian, called also by Suidas a Stoic philosopher, founded the celebrated Pergamene school of grammar, and became the great rival of Aristarchus, of the Alexandrian school. From his work on Homer, he is said to have been called Ὁμηρικος. He wrote commentaries on Hesiod, Euripides, and Aristophanes. Only a few fragments of his works are preserved.

CRATINUS. I. A comic poet of Athens, mentioned by Quintilian and Horace as one of the 3 great masters of the old comedy. He was a native of Attica, born about 520 B. C., died about 445 B. C. His private life seems to have been marked by many irregularities and excesses. Suidas calls him the "wine-bibber," as Aristophanes and Horace, indeed, had done before him. He was already far advanced in life before he entered upon his dramatic career. The "Archilochoi," supposed to have been his earliest production, was not exhibited till he was upward of 70 years of age; but he lived to achieve much for his profession, and at the advanced age of 97 died at the height of his fame, having just triumphed over Aristophanes himself. He found the Greek comedy a mere plaything, employed to excite merriment and laughter, and at once converted it into a terrible weapon for the chastisement of public and private vice. Horace particularly commends the public spirit and the impartial justice with which he exercised his censorship over the morals of his age. The uniform testimony of ancient writers places Cratinus in the first rank as a comic poet. His great rival, Aristophanes, was fully aware of his power. In the "Knights" he compares him to a torrent carrying every thing before it, and tells his fellow citizens that Cratinus was entitled to a high place in their regard, to a choice seat at the Dionysia, and to a public support in the Prytaneum. According to the best authorities he wrote but 21 dramas, 9 of which were successful in the Dionysiac contest. Not a single one of his dramas is now extant; only a few fragments remain to attest the excellence of his admired productions. II. A poet of the middle comedy, contemporary with Plato the philosopher, sometimes confounded with his elder and more celebrated namesake just mentioned. Eight plays are ascribed to him.

CRATIPPUS. I. A Greek historian contemporary with Thucydides. He continued the work of the great historian, and brought it down, according to Plutarch, to the time of Conon. The well-known words of Dionysius: "He wrote what Thucydides left unwritten," evidently show that Cratippus not only continued the history of Thucydides, but also supplied whatever omissions he thought he found in it. II. A celebrated Peripatetic philosopher. He was born at Mytilene, on the island of Lesbos, where he established a school of philosophy; but afterward having repaired to Athens, he became the instructor of Brutus and of M. Cicero, the son of the great Roman orator. Cicero himself pronounces high encomiums upon him in the *De Officiis*, declaring him the ablest of the Peripatetics whom he had ever known, and equal at least to the best of the school. Though highly esteemed by the ancients, he never produced, so far as we can learn, any important philosophical work. Cicero tells us that he believed in inspiration and in dreams, but rejected all other kinds of divination. He is supposed to have been the au-

thor of the work on dreams cited by Tertullian in his work *De Animâ*.

CRAVEN, a S. E. co. of N. C.; area estimated at 1,000 sq. m.; pop. in 1850, 14,709, of whom 5,951 were slaves. It borders on Pamlico sound, and is intersected by the Neuse river, navigable throughout the county. The surface is low, swampy, and in great part covered with pine forests, the turpentine and lumber procured from which are among the chief articles of export. The agricultural products in 1850 were 174,366 bushels of corn, and 92,788 of sweet potatoes. This county was formed in 1729, and was at first a precinct of Albemarle county. It was named in honor of the earl of Craven, one of the lords proprietors of the soil. Capital, Newbern.

CRAVEN, Charles, secretary to the proprietors of South Carolina, and governor of the colony from 1712 to 1716. He was the hero of the Yamassee war in 1715. That tribe of Indians having united the savages from Cape Fear to the St. Mary's, for the destruction of the colony at Ashley river, Gov. Craven immediately proclaimed martial law, laid an embargo on all ships to prevent the departure of men or provisions, and at the head of 1,200 men, a part of whom were faithful blacks, met the Indians in a series of desperate encounters, and finally drove them beyond the Savannah.

CRAVEN, Elizabeth. See Anspach.

CRAWFISH, a macrourous or long-tailed crustacean, of the order *decapoda*, and genus *astacus;* this genus is fluviatile, while the lobster, belonging to the same family but to the genus *homarus*, is marine. The body is elongated and somewhat compressed, and the abdomen large; it is covered by a corneous envelope or carapace, terminating anteriorly in a wide, short, flattened beak, which covers the base of the eye pedicles. There are 2 pairs of antennæ: the 1st pair of moderate length, with 2 terminal filaments; the external, or 2d pair, being much longer, with a large lamellar appendage on the upper surface of its pedicle. The mouth apparatus consists of 2 mandibles, 2 pairs of jaws, and 3 pairs of jaw feet, moving horizontally. The legs are 5 pairs, the 1st the largest, and ending in a 2-bladed nipper or claw, by which objects are seized in the pursuit of prey, and in self-defence; the 2d and 3d pairs are also didactylous, but smaller, and the 4th and 5th are single-pointed. The 5th thoracic ring is simply articulated to the preceding ones. The abdomen is of about the same width for its whole length, presenting on each side a series of laminæ prolonged so as to encase more or less the base of the false or swimming feet; the last segment is very wide, forming, with the 2 laminæ from the 6th ring on each side, a large caudal fin, nearly even when expanded, the external plate having a transverse joint at its posterior 3d, the middle plate being round at the end, with a tooth on each side posteriorly. The sternum forms no plastron, as in the crab; the pincers of the 1st pair of feet are not so large in proportion, and are without the angle seen in the lobster. The swimming feet are 5 pairs, long and narrow; in the females all end in wide leaf-like plates, with ciliated edges; in the males the 1st pair are styliform. The gills are very numerous, disposed in tufts, and arranged in rows at the base of the walking feet, and within the carapace; they are separated by cartilaginous plates, whose motions serve to introduce and expel the water, which issues at an aperture on each side of the mouth. According to Milne-Edwards, the duodenum has a great number of internal villosities, no valve between it and the rectum, the latter smooth, and no cæcal appendage, the opposite of which is the case in the lobster. The eyes have compound facets, and are supported on movable pedicles arising from the 1st segment of the head, and may be in a measure withdrawn into cavities answering the purposes of orbits. The organs of generation are distinct in the two sexes; the number of eggs is very great, and they are carried for a time attached to the false feet, under the tail. Like other decapods, the crawfish changes its shell annually, coming out with a new and tender one, which becomes hard in a few days; at each moult the animal increases considerably in size, and the change appears to be continued through life; the shell, which is an epidermic covering, consists of chitine united to calcareous salts. This genus also has the power of reproducing claws and feet which have been lost by accident. Their food is almost exclusively animal, both living and dead matter being eagerly devoured; fish, mollusks, aquatic larvæ, terrestrial insects, and sometimes their own species, form the principal sources of their subsistence. Their enemies are also many; mammals frequenting the water, aquatic birds, voracious fishes, and even insect larvæ, destroy great numbers of them, especially in their young state. They are considered luxuries on the table, and those who will not eat them catch a great many for bait for white perch and other fishes; they are caught in nets, and may be easily taken from holes and under stones. In some of the Russian rivers they attain a large size, and are caught for the sake of the calcareous masses found in their stomachs before the period of moulting; these concretions, the famous "crabs' eyes" and *yeux d'écrevisses* of the old pharmacopœias, consist of carbonate and phosphate of lime, and are no better than prepared chalk for the correction of stomachal acidity, for which they were formerly much employed. They delight in clear and running streams, but are common in lakes and ponds; they conceal themselves by day, and feed by night. The color is generally a light yellowish brown. The European crawfish (*A. fluviatilis*, Fabr.) has the large claws studded with granulations, and the beak with a tooth on the side near its internal third. Among the American species are the *A. affinis* (Say), and *A. Bartonii*

(Bose.), found in the southern and western rivers; in these the claws and the carapace are less granular. Other species are described in South America and Australia by Milne-Edwards. Crawfish swim rapidly by means of the tail, whose strokes propel them backward; they crawl well on the bottom, and are sometimes seen at a considerable distance from streams, using holes filled with water, and occasional pools, as places of retreat. From their propensity to eat carrion, Audubon calls them "little aquatic vultures." They are fond of burrowing in the mud, and from this habit are often great pests, undermining levees and embankments, frequently to the serious loss of the miller and the planter; it is stated that on account of the depredations of these animals, the owners of the great dam in the Little Genesee river have been once compelled to rebuild it. In the Mammoth cave of Kentucky some of the crawfish are blind; they have the eye pedicles, but no facets, only simple integuments covered with hairs; very probably, as in the case of the blind fish of the same cave (*amblyopsis spelæus*), internal rudiments of a visual organ would be found, especially as it is said that some of these crustacea have well developed eyes, as also do the crickets which live in the cave; the non-development of the external eye may be owing to the absence of the stimulus of light through several generations. There is no evidence that the species within and without the cave are different, and it is altogether probable that the progeny of the blind crawfish would have eyes, if raised under the ordinary influences of sunlight. The popular name of the crawfish is "fresh-water lobster."

CRAWFORD, the name of counties in several of the United States. I. A N. W. co. of Penn., bordering on Ohio, intersected by a number of creeks; area, about 975 sq. m.; pop. in 1850, 37,849. It has an undulating surface, and a soil of good quality, but better adapted to grazing than to tillage. Iron ore and lime marl are found in considerable quantities. Lumber is abundant, and forms one of the chief articles of export. Grain, potatoes, hay, and dairy produce, are the other staples. In 1850 the harvest amounted to 387,556 bushels of Indian corn, 142,414 of wheat, 418,751 of oats, and 165,662 of potatoes. There were 1,267,436 lbs. of butter made. The public schools numbered 9,906 pupils; there were 63 churches, 5 newspaper offices, 140 saw mills, 15 flour and grist mills, 3 woollen factories, 2 iron founderies, 16 tanneries, and various other mills, factories, &c. The county was organized in 1800, and named in honor of Col. William Crawford, who was killed by the Indians at Sandusky, Ohio, in 1782. Capital, Meadville. II. A W. co. of Ark.; area, 585 sq. m.; pop. in 1854, 4,658, of whom 530 were slaves. It borders on the Indian territory, and is bounded on the S. by Arkansas river, here navigable by steamboats. The surface is mountainous, and some of the highest summits in the state are in this county. Boston mountain is estimated to have an elevation of 2,000 feet. Stone coal and other minerals are found in several parts. The productions in 1854 were 360,669 bushels of Indian corn, 20,025 of wheat, 69,600 of oats, and 329 bales of cotton. In 1850 there were 6 churches, 2 newspaper offices, and 405 pupils attending public and other schools. Capital, Van Buren. III. A central co. of Ga.; area, 289 sq. m.; pop. in 1852, 8,912, of whom 4,803 were slaves. It is bounded S. W. by Flint river, and drained by several creeks. The land is uneven, and of various qualities. In the north it is moderately fertile, and in the south sterile. The arable land produces cotton, grain, and sweet potatoes; the rest of the surface is chiefly covered with pine forests. In 1850 the county yielded 7,477 bales of cotton, 339,426 bushels of Indian corn, 35,284 of oats, and 93,100 of sweet potatoes. There were 20 churches, and 367 pupils attending public schoools. Named in honor of William H. Crawford, U. S. senator from Georgia. Capital, Knoxville. Value of real estate in 1856, $1,172,600. IV. A N. co. of Ohio; area, 412 sq. m.; pop. in 1850, 18,177. The surface is level, but elevated, and the soil of moderate fertility. The southern part is occupied by pastures, and the principal production of the northern is wheat. In 1850 the county yielded 275,653 bushels of Indian corn, 133,153 of wheat, 16,000 tons of hay, and 108,874 lbs. of wool. It contained 39 churches, and the public schools numbered 4,740 pupils. Capital, Bucyrus. V. A S. co. of Ind., bordering on Ky., bounded S. by the Ohio river, and drained by Blue river; area, 280 sq. m.; pop. in 1850, 6,524. The valleys of the streams are productive, but nearly all the rest of the land is rugged and sterile. Coal, iron, and limestone are the most valuable minerals. Lumber, flour, pork, and beef are exported in considerable quantities. The productions in 1850 were 183,930 bushels of Indian corn, 2,009 of wheat, 37,397 of oats, and 918 tons of hay. There were 11 churches, and 1,418 pupils attending public schools. Capital, Leavenworth. VI. An E. co. of Ill.; area, 420 sq. m.; pop. in 1855, 10,152. It is separated from Indiana on the E. by the Wabash river, and drained by Embarras river and its N. fork, the former passing through the S. W. part, and the latter flowing along the W. boundary. The surface is occupied in great part by fertile prairies. In 1850 the productions were 453,955 bushels of Indian corn, 16,943 of wheat, 5,001 of oats, and 1,411 tons of hay. There were 7 churches, and 620 pupils attending public schools. Named in honor of William H. Crawford, U. S. senator from Georgia. Capital, Palestine. VII. A S. E. co. of Mo.; area, 1,380 sq. m.; pop. in 1856, 7,672, of whom 237 were slaves. It is intersected by Maramec river, and drained by 2 of its branches. The surface is much diversified, and in many parts hilly. It is occupied by tolerably fertile prai-

ries and tracts of excellent timber. The valleys and river bottoms are generally very fertile, but the county is less remarkable for its agricultural productions than for its great mineral wealth. The hills contain very rich mines of copper and iron, the latter being extensively worked. Lead is also found in various localities, and stone is obtained in the vicinity of the iron district. The productions in 1850 were 297,133 bushels of Indian corn, 26,482 of wheat, 48,440 of oats, and 597 tons of hay. There were 7 churches, and 280 pupils attending public schools. Capital, Steelville. VIII. A S. W. co. of Wis., separated from Iowa by the Mississippi river, bounded S. E. by the Wisconsin; area, 612 sq. m.; pop. in 1855, 3,323. The surface is hilly, and occupied partly by prairies. The productions in 1850 were 9,655 bushels of Indian corn, 9,522 of wheat, 16,644 of oats, and 8,688 of potatoes. There were 4 grist mills, 9 saw mills, 1 newspaper office, 1 church, and 226 pupils attending public schools. Organized in 1818. Capital, Prairie du Chien. IX. A N. co. of the S. peninsula of Mich., recently erected, and not included in the census of 1850. It is drained by the sources of the Au Sable river. X. A newly formed and thinly settled co. in the W. part of Iowa, intersected by Boyer and Soldier rivers; area, about 600 sq. m., very little of which is under cultivation; pop. in 1856, 235. The productions that year were 878 bushels of wheat, 470 of oats, 11,135 of Indian corn, 1,080 of potatoes, 3,867 lbs. of butter, and 310 of wool.

CRAWFORD, George W., an American statesman and lawyer, born in Columbia co., Ga., Dec. 22, 1798. He was graduated at Princeton college, in New Jersey, in 1820, and on his return to Georgia became a law student in the office of the Hon. Richard Henry Wilde in Augusta, and was admitted to practice in 1822. In 1827 he was elected attorney-general, which office he retained until 1831. In 1837 he was elected a representative in the legislature from Richmond co., and, with the exception of one year, he continued to represent that county until 1842. In 1843 he was elected a representative to congress, but the same year was nominated by the whig convention as their candidate for governor, and elected by a large majority. His administration gave great satisfaction, and he was reëlected in 1845. In 1849 Mr. Crawford was appointed secretary of war in President Taylor's cabinet, which office he held until the death of the president, when he resigned. He has since lived in retirement at his home in Richmond co.

CRAWFORD, Nathaniel Macon, D.D., an American divine, born near Lexington, Oglethorpe co., Ga., March 22, 1811, was graduated at Franklin college (university of Georgia), Aug. 5, 1829. He studied law with his father, the Hon. William H. Crawford, and was admitted to the bar, but never practised. In 1837 he was elected professor of mathematics in Oglethorpe university, Ga., which office he held until the close of 1841. In 1843 he was licensed to preach, and was ordained in the Baptist ministry in 1844. He was pastor of the Baptist church in Washington, Ga., during the year 1845, and of the Baptist church in Charleston, S. C., in 1846. From 1847 to 1854 he filled the chair of Biblical literature in Mercer university at Penfield, Ga. In December, 1854, he was elected to the presidency of Mercer university, and held the office during the years 1855 and 1856, when he resigned. He filled the chair of mental and moral philosophy in the university of Mississippi during the spring session of 1857. In September of that year he resigned this position, and accepted a professorship in the western Baptist theological seminary at Georgetown, Ky., where he remained until July, 1858. In the mean time, having been reëlected to the presidency of Mercer university, and strongly solicited to return to that institution, he did so, and is now (1859) its presiding officer. In 1857 he was elected president of the Bible revision association. Dr. Crawford has written many articles for periodicals, and several small works on some of the tenets of his church. In 1858 he published a volume of 442 pages entitled "Christian Paradoxes," which has been favorably received by the denomination and the press generally. He is considered one of the first pulpit orators of the Baptist church in the South.

CRAWFORD, Quintin, an English translator and author, born at Kilwinning, Sept. 22, 1743, died in Paris, Nov. 23, 1814. He went in early life to the East Indies, where he served in the war against Spain. After the peace he became president of the company of the Indies at Manila, and in a short time gained a considerable fortune. Returning to Europe in 1780, he travelled in Italy, Germany, and Holland, and finally established himself at Paris, where he formed valuable collections of books and paintings. Obliged to leave France at the revolution, he resided successively at Brussels, Frankfort, and Vienna, but returned as soon as he was able to Paris, to the task of restoring the collections which had been dispersed and sold in his absence. After the rupture of the peace of Amiens, he was allowed to remain at Paris, through the protection of Talleyrand and the empress Josephine. He was the author of a "History of the Bastile, with a Disquisition upon the Prisoner of the Iron Mask," "Essays on French Literature," "Historical Essay on Swift, and his Influence on the English Government," "Sketches relating to the History, Learning, Religion, and Manners of the Hindoos," and other works, some of which are published in English and some in French.

CRAWFORD, Thomas, an American sculptor, born in New York, March 22, 1814, died in London, Oct. 10, 1857. In early childhood he manifested an extraordinary fondness for art, and from the time when he could guide a pencil correctly until the age of 14 his leisure hours, and many of those which should have been em-

ployed in study, were devoted to drawing and sketching, or to explorations of print shops and picture auctions. His father placed him at a drawing school, and finding him averse to a mercantile or professional life, allowed him to enter the establishment of a wood carver. In this occupation his talent developed rapidly, and at the age of 19 he entered the studio of Messrs. Frazee and Launitz, monumental sculptors in New York. At the same time he attended the schools of the national academy of design. His ambition, however, prompted him to enter a higher walk in his art, and at the expiration of 2 years, during which he executed several monumental designs, and worked upon portrait busts of Chief Justice Marshall and others, he adopted the advice of his friend Launitz, and departed for Italy. He arrived in Rome in the summer of 1835 with a slender purse, but with what to an enthusiastic art student was of more value than money, a letter of introduction to Thorwaldsen, with which he had been furnished by Launitz. The Danish sculptor received him kindly, and invited him to work in his studio, an offer which Crawford accepted forthwith. For several years he labored with an earnestness which excited in his friends mingled feelings of admiration and anxiety. He indulged in no relaxations, and seemed indifferent as to his health or physical wants, but was wholly absorbed in the study of his art. Such devotion could not fail to attract attention, and the young sculptor began to be intrusted with commissions for portrait busts and copies in marble. The sums received for these barely sufficed for his support and the purchase of the necessary materials; but he was glad to work for any remuneration, feeling that he was in no position to refuse, and that excellence could only be attained by incessant labor. As an illustration of his enthusiasm and physical energy, it is stated that during 10 weeks in 1837 he modelled 17 busts to be put in marble, and copied in marble the figure of Demosthenes in the Vatican. In 1839, having previously executed a few original pieces, he designed his "Orpheus," the work which first brought him into notice in America, and which elicited the warm commendation of Gibson and Thorwaldsen, the latter of whom, it is said, called it the most classic statue in the studios of Rome. Mr. Charles Sumner, who saw it in Rome in the latter part of that year, was so struck with its merits, that on his return to Boston he procured, by subscription, the means of sending Crawford an order for a copy in marble. Its reception in America, where it was exhibited with others of Crawford's works, formed an era in the life of the artist, from which dates the commencement of the reputation he subsequently enjoyed. The statue is now in the possession of the Boston Athenæum. Crawford was now enabled to give more attention to ideal composition, and the numerous designs in mythology and sacred history which he undertook indicated a steady gain in executive skill and confidence. To this period may be referred his more purely classic subjects and his scriptural bass-reliefs, remarkable for the spirit and propriety of their treatment. His industry seemed to increase with the favorable turn in his fortunes. He fitted up large studios in the piazza Barberini, which soon became a favorite resort of strangers from the number of striking original works always to be seen there. In 1844 he visited America, and was married to Miss Louisa Ward, daughter of the late Samuel Ward, of New York. During the next summer he modelled a remarkable bust of Josiah Quincy, sen., for the library of Harvard university, and returned to Europe with numerous commissions for new works. In 1849 he made a 2d visit to the United States, and within a few days after reading in a Richmond newspaper the proposals for the monument to be erected to Washington by the state of Virginia, he prepared and despatched his model, which was unanimously adopted as the best offered. From the period of his return to Rome in 1850 until he was incapacitated for work, he was chiefly engaged on that series of grand historical and allegorical pieces which attested the finest development of his artistic powers. One of the most remarkable of these was the bronze statue of Beethoven, which he was commissioned by Mr. Charles C. Perkins, of Boston, to execute for the Boston music hall. The completion of this work at the foundery in Munich was celebrated by a musical festival, at which the royal family of Bavaria and an immense concourse of people were present. It was deposited in its destined place with no less ceremony. The artist declined to receive any remuneration for his personal labor in this work. The colossal equestrian statue of Washington, 25 feet in height, was subsequently cast in Munich under the artist's personal superintendence, and arrived in Virginia in the beginning of 1858. The people of Richmond testified their enthusiasm by dragging it to Capitol hill, where it now stands. Its pedestal rests upon a star-shaped elevation with 6 points, on which are to be placed statues of Patrick Henry, Jefferson, Lee, and other illustrious Virginians. None of the latter were completed at the artist's death, but will be finished from his designs. The admiration which these works excited in Europe procured his admission to the royal academies of Munich and St. Petersburg, and the academy of St. Mark in Venice. Crawford had meanwhile received an important commission from congress to furnish marble and bronze statuary for the new capitol at Washington, and among the most remarkable of his designs were those which he prepared for the pediment and the bronze doors. In the former the figure of liberty, who is supported on either side by allegorical representations of the arts, commerce, civilization, &c., is particularly fine. In the latter are representations of law and justice. The grandest work of this series, however, and perhaps of all which he has designed, is the colossal statue of the genius of America, which is destined for the pinnacle of the capitol dome.

It is a majestic and graceful female figure draped to the feet, and wearing an expression of conscious power and magnanimity. This work, the model of which received the sculptor's last touches, is yet to be cast in bronze. As an illustration of the versatility of Crawford, it may be mentioned that while engaged on these works he executed his touching group of the "Babes in the Wood," and the "Hebe and Ganymede," beside various portrait busts, including one of James Otis for the chapel in the Mt. Auburn cemetery, near Boston. In 1856 he revisited America, leaving his family there, and returned alone to Rome. A cancerous tumor on the brain soon after manifested itself, and he was obliged to renounce the practice of his art. He was successively removed to Paris and London for the benefit of medical treatment, and died after an intensely painful illness. The industry of Crawford finds few parallels among ancient or modern sculptors. During his artistic career he finished upward of 60 works, many of them colossal, and left about 50 sketches in plaster and designs of various kinds, most of which will be finished by his assistants. His chief mythological subjects are the "Genius of Mirth," the "Muse," "Autumn," "Cupid," "Flora," "Io," the "Peri," "Apollo," "Homer," "Diana," "Vesta," "Sappho," the "Archer," "Paris presenting the Apple to Venus," "Mercury and Psyche," "Jupiter and Psyche," "Psyche Found," "Nymph and Satyr," a series of 4 bass-reliefs, "Boy and Goat," &c. His Scriptural compositions included "Adam and Eve," "David and Goliath," "David before Saul," the "Shepherds and Wise Men before Christ," a group of 24 figures; "Christ disputing with the Doctors," 12 figures; "Christ ascending from the Tomb," and "Christ raising Jairus's Daughter;" the "Daughter of Herodias," "Repose in Egypt," "Eve Tempted," "Eve with Cain and Abel," "Lead us into Life Everlasting," a single figure of Christ, "Christ blessing little Children," and "Christ at the Well of Samaria." Among his miscellaneous works, in addition to those mentioned, are the group of the "Dancers," 2 life-size statues of children, which have had much popularity, statues of Channing, Washington Allston, Henry Clay, and busts of Commodore Hull, Charles Sumner, Kenyon the English poet, Mrs. Crawford, the latter a masterpiece of finish, and many others.

CRAWFORD, William Harris, an American statesman, born Feb. 24, 1772, in that part of Amherst co., Va., afterward erected into Nelson co., died in Elbert co., Ga., while on his way to attend the court of which he was judge, Sept. 15, 1834. His father, Joel Crawford, was of Scotch descent, and a frontier farmer in moderate circumstances. Following the tide of emigration then setting southward along the Blue Ridge, he removed in 1779 to Edgefield district, S. C., and settled on Stevens's creek, which enters the Savannah some 30 miles above Augusta. He was a whig in his political principles, and when in 1780 the British overran the states of Georgia and South Carolina, he was taken prisoner, and thrown into Camden gaol, from which imprisonment he was released on the security of some of his loyalist neighbors. In 1783, the revolutionary war being concluded, he removed across the Savannah river into Georgia, and settled on one of its tributaries, Kiokee creek, in the present county of Columbia. The elder Crawford died a few years after, leaving his family in reduced circumstances. The young Crawford had early displayed an aptitude for learning, and by attendance at such schools as the neighborhood afforded, had qualified himself to act as teacher. Upon this occupation he entered at the early age of 16, and followed it at intervals for several years, thus assisting his mother in the support of the family. Dr. Waddell having established his classical academy in Columbia co.—the same at which John C. Calhoun and William Lowndes were not long after pupils—young Crawford resolved to improve the opportunity thus afforded. He entered this academy in 1794, then 22 years old, and remained there 2 years, the latter portion of the time acting as usher. He then became assistant teacher and afterward principal of an academy in Augusta, and having pursued in the mean time the study of the law, was in 1798 admitted to the bar. The following spring he removed to Lexington, Oglethorpe co., and commenced practice. Soon after his admission to the bar he assisted in compiling the first digest of the laws of Georgia. Both his physical and mental endowments were well calculated to insure him success as a lawyer. He was of a very strong constitution, was 6 feet 3 in height, was every way finely proportioned, and, though not graceful in his manners, of easy and agreeable address. He was quick in his perceptions, rapid in combination, and clear and distinct in his opinions, which he maintained with unshaken firmness. He did not go much into detail or incidents, but rested on a few strong points. He indulged in no rhetorical flourishes, and his speeches, always to the purpose, seldom exceeded half an hour in length. In 1802, the then leader of the bar on that circuit having been elected to congress, Mr. Crawford succeeded to his place. The next year he was himself elected to the state legislature, of which he continued a member for 4 years. In 1804 he was married to Susannah Girardin of Augusta, after a 7 years' engagement, which he now first felt himself in a pecuniary position to fulfil. Upon his marriage, which proved a very happy one, he settled on a small estate near Lexington called Woodlawn, where, except when engaged in the public service, he continued to reside for the remainder of his life. By this marriage he became the father of 5 sons and 3 daughters. The only measure of general interest in which he appears to have participated as a member of the state legislature, was a resolution introduced by him and adopted by both branches, urging Jefferson to stand for the presidency a third time. In the

local affairs of the state he took an active interest, and gave such evidences of his ability, that in 1807, on the resignation of Abraham Baldwin as United States senator from Georgia, Mr. Crawford was chosen to fill his place. But he did not reach this elevation without going through what may be considered as at that time almost the ordinary routine of public life in Georgia. He had been engaged in two duels. In the first, which grew rather out of professional than political differences, he killed his opponent, a Mr. Van Allen, a lawyer, lately from New York, and a cousin of Martin Van Buren. His second duel, in which he was himself wounded in the wrist, was fought with Gen. John Clark, who remained for 20 years his bitter political opponent, and the head of a political party warmly opposed to him. Mr. Crawford reached Washington at a very important crisis. The restrictions upon commerce, growing out of Napoleon's decrees and the British orders in council, had thrown the country into a great excitement, which was soon still further increased by the embargo policy recommended by President Jefferson, and adopted by congress. Mr. Crawford had been elected to the senate as a supporter of the administration; but though the embargo was warmly urged as an administration measure, he showed his independence by voting against it. It was impossible, however, if he wished to maintain his political associations, to persevere in this opposition, and at the next session of congress he both spoke and voted against its repeal. The calm and sound judgment of Mr. Crawford, and the moderation of his political views, recommended him to the esteem and confidence of Mr. Gallatin, of whose policy as secretary of the treasury under President Madison he became the exponent in the senate. It was in this character that, in 1811, having then been reëlected to the senate, he sustained with much ability the proposal of Mr. Gallatin for renewing, upon certain conditions, and under certain limitations, the charter of the first bank of the United States. Upon this question the contest was very severe. In addition to those old democratic champions, Smith of Maryland, Leib of Pennsylvania, and Giles of Virginia, the opposition in the senate was led on by the impetuous young Henry Clay, at that time a vehement advocate of the doctrine of the unconstitutionality of a United States bank. After a warm debate the enacting clause of the bill was struck out by the casting vote of Vice-President Clinton, a similar bill in the house being indefinitely postponed by one majority. That session was exceedingly stormy. Toward the close of it a collision took place between John Randolph and Eppes, the son-in-law of Jefferson, both members of the house, which drew out a challenge from the latter. Mr. Crawford, probably from his experience as a duelist, was invited to act as one of the seconds, in which capacity he successfully exerted himself to bring about an explanation without any fighting. When, in March, 1812, Vice-President Clinton was disabled, by the sickness of which he soon after died, from acting as president of the senate, Mr. Crawford was chosen president *pro tem.;* an appointment the more important as after Clinton's death, in case the office of president became also vacant, Mr. Crawford as president of the senate would have succeeded to it. In common with Madison, Gallatin, and other older members of his party, Mr. Crawford was opposed to the policy of war with Great Britain, and in that point of view he was more consistent than some others in warmly opposing any augmentation of the navy. But Madison and Gallatin having yielded to the demands of the younger and more ardent section of the party, Mr. Crawford went with them and voted for the war. In 1813, having just refused the secretaryship of war, Mr. Crawford was appointed minister to France as successor to Joel Barlow. The political confusion of that country, incident upon the downfall of Napoleon, was not very favorable to diplomatic discussions, but he had the opportunity of witnessing some of the most remarkable occurrences of modern history. He also took a warm interest in the negotiations at Ghent, and was decidedly in favor of peace if it could be obtained, without any mention of the impressment question, and that too even without waiting for definite instructions to that effect from Washington. He first received the news of peace at the house of Madame de Staël, where it was communicated to him by the duke of Wellington, with whom he had formed a friendly acquaintance. During his residence in France he acquired the friendship of Lafayette, who appointed him agent for his American lands, and with whom after his return home he carried on a confidential correspondence. In 1815 he asked a recall, and the senate having refused to confirm Gen. Dearborn, whom after the peace Madison had nominated as secretary of war, Mr. Crawford, while still on his voyage home, was appointed to fill his place. The next year, on the retirement of Alexander J. Dallas, he was appointed secretary of the treasury. There were those who desired to support him as a candidate for the presidency instead of Monroe; indeed, he received a large vote in the congressional caucus; but upon Monroe's accession he continued to hold the secretaryship of the treasury, having J. Q. Adams and J. C. Calhoun as his colleagues in the cabinet. The course of events, and especially the experience of the late war, had led a portion of the democratic party to alter their views very essentially as to the powers and duties of the federal government. Abandoning that strict limitation of federal authority, power, and patronage, of which Jefferson had been the champion, many among them had begun to favor a liberal interpretation of the powers of the government, and a generous expenditure of money, especially in facilitating trade and intercourse between the states by means of internal improvements. John C. Calhoun was at this time an active champion

of these new views. They were opposed by Crawford, both in his character of a statesman and as the head of the treasury, at that time limited in its resources, and driven to loans even in time of peace. He was for adhering to the old Jeffersonian policy, and was denounced in consequence in Calhoun's newspaper organ at Washington as a "radical." Thus sprang up a warm political and even personal hostility between these two able men, entered into also by their respective states, between which a strong feeling of jealousy, and even antipathy, transmitted from colonial times, was not yet entirely extinct. This feeling of hostility was aggravated upon the coming up of the question of a successor to Mr. Monroe. Mr. Crawford, ever since the withdrawal of his claims at the former election in favor of Monroe, had been considered as in some sense the destined successor. He was nominated as such by a congressional caucus, held Feb. 14, 1824. That caucus, however, was but thinly attended, and failed to command general respect. All the other candidates, Calhoun, Jackson, Adams, and Clay, joined against him; and among other violent assaults upon him, was one in the house of representatives itself, introduced just at the end of the session, based on certain charges made by Ninian Edwards, late a senator from Illinois, and just appointed minister to Mexico, to which country he was then on his way. Instead of allowing these charges (which involved official misconduct as secretary of the treasury, and had already been brought forward in a Washington newspaper) to lie over till after the presidential election, which seemed to be the object of those who had introduced them, Mr. Crawford and his friends demanded an investigation at once. This was granted, and a committee was appointed, of which Daniel Webster, Edward Livingston, and John Randolph were members. Mr. Crawford, though sick in bed at the time, dictated a conclusive reply, and the affair ended in a unanimous report of the committee declaring the total futility and falsity of the charges, and in the resignation by his accuser of his diplomatic appointment. The disorder under which Mr. Crawford was laboring was paralysis, brought on, it is stated, by the improper use of lobelia for an attack of erysipelas during a temporary absence from Washington. His sickness was long and severe, and though perhaps it had little influence on the vote given for him as president (he obtained all the electoral votes of Virginia and Georgia, 5 in New York, 2 in Maryland, and one in Delaware, 41 in all), it wholly destroyed any chance of his election by the house, and removed him henceforth from the political arena. Mr. Crawford continued for some time a great invalid. He could not see to write, and had not the physical ability to encounter any labor. He was assisted in preparing his last treasury report by Asbury Dickins, then a clerk in his department, who had also assisted in preparing his defence against Edwards. He gradually improved, but never fully recovered. J. Q. Adams offered to continue him as secretary of the treasury, but he declined, and returned home to Georgia. Notwithstanding his political rivalry with Mr. Clay, he still remained on friendly terms with him, and in a letter written in 1828, assured him that as between Jackson and Adams he should have decided as Clay did. Mr. Crawford's pecuniary means were not large, and a vacancy occurring in May, 1827, on the bench of the northern circuit, the same in which he had formerly practiced, he accepted a temporary appointment from Governor Troup to fill it. In November following he was chosen by the legislature for the remainder of the vacant term, in which position (the judges holding office for 3 years only) he was continued at two subsequent elections in 1828 and 1831. During his time there was no court for the correction of errors in Georgia. There was a convention of the circuit judges annually to consult on questions submitted by each other, but no judgment could be rendered, the action of the convention being wholly advisory. During the 7 years that he presided as judge of the northern circuit, Mr. Crawford acted as chairman of this convention. Though his disorder affected him both physically and mentally, and though sometimes annoyed by the "silly speeches" of counsel, he made a much better judge than would have seemed possible to those familiar with his paralyzed state. He was strongly opposed to the nullification movement. To the last, he retained his social temper and admirable conversational talent. He loved to tell anecdotes, and told them well. He was a hearty laugher, negligent in his dress, simple in all his arrangements, and totally regardless of artificial dignity. He was extremely affectionate to his children, teaching them himself, romping with them, arguing with them, and accustoming them to treat him familiarly and confidingly. In the family, Woodlawn was familiarly known as Liberty hall. His wife and several children survived him. In religion, he inclined to the Baptist persuasion, and though not zealous was a sincere believer. He is generally regarded as the greatest of the citizens of Georgia.

CRAWFORDSVILLE, a prosperous town of Union township, and capital of Montgomery co., Ind. It is finely situated in a fertile and undulating region on the banks of Sugar creek, and contains a number of imposing private and public edifices. It is remarkable for its educational advantages, and is the seat of Wabash college, founded in 1835, and regarded as one of the best institutions of the kind in Indiana. The original college buildings, together with a library of 3,000 volumes, were destroyed by fire in 1838. Crawfordsville also contains a county seminary, a female academy, and 2 newspaper offices. A railroad connects the town with Lafayette, 28 miles distant. Pop. in 1853 estimated at 2,500.

CREAM OF TARTAR. The chemical composition of this useful salt is: tartaric acid two equivalents, = 132; potassa one, = 47.2; and

water one, = 9. It is a bitartrate of potassa purified from the crude tartar or argol, which collects in a crystalline deposit upon the bottom and sides of wine casks during the fermentation of the wine. As the saccharine matters which hold this in solution are converted into alcohol, the salt is precipitated in a crude state, together with some tartrate of lime and the coloring matter of the wine. Red wines give a red color to the crude article. When the crude salt is dissolved in boiling water, and this is allowed to cool, crystals of the cream of tartar are deposited and form a crust on the bottom of the vessel, cold water holding in solution only $\frac{1}{30}$ of its weight of the salt, and boiling water $\frac{1}{18}$. The crust is redissolved in boiling water, and 4 or 5 per cent. of pipe clay is added. On evaporating the solution, the clay precipitates with the coloring matter, and the salt of tartar is deposited in white crystals. These are bleached by being spread upon cloths for some days and dried, and then constitute the cream of tartar of commerce. It is usually sold as a powder, and in this state is liable to have been mixed with various substances used for its adulteration, as chalk, clay, gypsum, sand, flour, &c. It is therefore better to purchase it in the crystalline form in which it is received from the French manufacturers. It is, however, never pure, always containing a small percentage of tartrate of lime. Cream of tartar is much used in medicine, as well for its agreeable cooling properties when made into a drink, as for its more powerful qualities as a cathartic when administered in large doses. A refreshing beverage called imperial is prepared by dissolving half an ounce in 3 pints of boiling water, and adding 4 ounces of white sugar and half an ounce of fresh lemon peel. Cream of tartar and tartrate of antimony compose the medicine tartar emetic. Rochelle salt is prepared by adding cream of tartar to carbonate of soda, by which a tartrate of potassa and soda is produced. When decomposed by heat, cream of tartar is converted into a pure carbonate of potassa. Mixed with half its weight of nitrate of potash and deflagrated, it forms the flux called black flux, used for crucible assays. White flux is prepared with two parts of nitre to one of cream of tartar. In making bread, cream of tartar is often usefully employed, mixed with half its weight of carbonate of soda. The excess of acid produces a slow effervescence, and the escape of carbonic acid gas, distending the dough, causes it to rise.

CRÉBILLON, Prosper Jolyot de, a French tragic poet, born at Dijon, Jan. 13, 1674, died in Paris, June 17, 1762. His father placed him in the office of an attorney who happened to be an enthusiastic lover of the drama, and encouraged his young clerk to devote himself to dramatic literature. His first tragedy, *Idoménée*, performed in 1705, though not a masterpiece, was superior to the weak imitations of Racine and Corneille current at that time. His next play, *Atrée*, appeared in 1707, and produced an impression by its gloomy plot and energetic style. *Electre* succeeded in 1709; and 2 years later, *Rhadamiste et Zénobie*, which is still considered his best production. The mainspring of Crébillon's plays is terror, and it must be conceded that he uses it with power. His next tragedy, *Xerxès*, was a failure; and *Sémiramis*, performed in 1717, and *Pyrrhus*, in 1726, were little more successful. He now kept aloof from the stage for 22 years. Having squandered his large earnings and lost his father and his wife, he retired to a miserable garret, where his sole companions were dogs, cats, and ravens, and where he lived neglected by all his friends, except his son, who tried in vain to withdraw him from his isolation. In 1731, however, the French academy elected him one of their number; and the new academician wrote a poem as his reception discourse. Some 14 years later, Mme. de Pompadour, who was dissatisfied with Voltaire, thought of bringing Crébillon into competition with him. The old dramatist received a pension of 1,000 livres, and was encouraged to resume his former calling. He now completed his tragedy of *Catilina*, which was, Dec. 12, 1748, performed in a style of unusual splendor at the king's expense, and warmly applauded by the court party, while his superiority over Voltaire as a tragic poet was loudly proclaimed. The latter, smarting under what he considered an insult, replied by undertaking subjects already treated by his rival, and handling them in a manner evincing a greater degree of skill, if not of genius. Crébillon's last effort was his *Triumvirat*, which he wrote when over 81, and which was received with forbearance and respect. Among French tragic poets Crébillon ranks next to Corneille, Racine, and Voltaire.—Claude Prosper Jolyot de, a French novelist, the son of the preceding, born in Paris, Feb. 14, 1707, died there, April 12, 1777. His character afforded a striking contrast to that of his father. He was a gay companion, full of wit and humor, and he wrote a series of novels which were in accordance with the licentiousness of the age, and brought him not only great fame but also a wife; Miss Stafford, a young, handsome, rich English lady, of noble birth, having been so much pleased with them as to cross the channel, and to offer her hand, which was at once accepted by the lucky author. Crébillon's novels, notwithstanding their popularity during the 18th century, are now but little read. The least objectionable is entitled *Les égarements du cœur et de l'esprit*. He was also a ready and witty song-maker, and aided in the establishment of the lyric society known as *Le caveau*.

CRÉCY, or Cressy (anc. *Crisiacum*), a village of France, in the department of Somme (Picardy), 11 m. N. of Abbeville; pop. 1,785. The village is situated on the small river Maye, a tributary of the Somme, in the midst of a grain and grass-growing country. It has tanneries, soap and oil manufactories, and considerable trade in wood from the adjoining for-

ests. An annual fair is held here, Aug. 25 and 26. The objects of interest are the tower of Edward III., the valley of Cleves, and the stone cross of the king of Bohemia. Cardinal John Lemoine was born here.—Crécy owes its celebrity to the famous battle fought, Aug. 26, 1346, between the English under King Edward III. and the French under King Philip of Valois, in which the French army was destroyed. The English, on one of their plundering expeditions into Normandy, had penetrated within sight of Paris, and were retreating to the coast when the French army came upon them. Some discrepancy exists in the estimate of the respective forces. Froissart, whose statement is followed by Hume and others, makes the English 30,000 to 40,000, and the French 100,000 to 120,000. Turner, in his "History of England during the Middle Ages," says the English army was in 3 divisions: the 1st, under the Black Prince, Edward prince of Wales, comprised 800 men-at-arms, 2,000 archers, and 1,000 Welsh; the 2d, under the earl of Northampton, 800 men-at-arms, and 1,200 archers; and the reserve, under the king, not engaged in the battle, 700 men-at-arms and 2,000 archers. Allowing for retainers, the total number may be computed at 17,000. It is difficult to comprehend how a greater number of fighting men could be assembled on the coast with the imperfect means of transport then at command. Reducing the estimate of the French in the same ratio, we may assume the battle to have been fought between 17,000 English and 50,000 to 60,000 French. Even these numbers give it the magnitude of a great battle. Edward saw the danger to which a hasty retreat would expose him in face of the enemy's superior force; he therefore determined to make a stand, in hopes to check their further advance. Selecting a rising ground near Crécy, he drew up his army on the ascent, and threw up trenches on his flanks, with a wood in his rear which he also secured by intrenchment. Villani alleges that Edward had 6 pieces of artillery, which he posted so as to sweep the enemy's advance. Artillery had been recently invented, and was known both in France and England, but does not appear to have been in use in the field until the present occasion. Philip was confident that he had only to force the English to an engagement to destroy them utterly; hence he neglected precautions, and advanced his troops pell-mell from Abbeville, with little attention to order or discipline. His advanced guard of Genoese bowmen began the attack, but rain having fallen, their arrows fell short. The English, taking their bows from their cases, sent a shower of clothyard shafts that drove the Italians back on the cavalry of the duke d'Alençon, who, enraged at their cowardice, ordered his troopers to cut them down. The English artillery opened fire, and the prince of Wales (aged 15) charged with his men-at-arms on the struggling mass. An opportune movement of the French retrieved their fortunes, and for a long time the battle hung doubtfully. Lord Cobham despatched Sir Thomas Norwich to the king requesting him to send the reserve to the assistance of the prince. "No," said Edward; "tell my boy he must win his spurs." This speech invigorated the English. They again charged. The duke d'Alençon was killed; the French line was broken, and the Welsh, rushing into the *mêlée*, with their long knives stabbed the horses and butchered those who fell. Philip made a final effort to recover the day, but without effect. The rout had become a flight. Edward's reserve, and indeed the whole English army, pursued the fugitives, sparing none, till darkness put an end to the bloodshed. Next morning the English were guilty of an act which disgraces their victory. Fog having come on, many parties of French were wandering in search of the main body; the English set up on the eminences the French standards they had taken, and all who were allured by the signal were massacred. Thirty thousand French perished, including 2,600 knights and gentlemen, and 4,000 men-at-arms. Beside the duke d'Alençon, the king's brother, the kings of Bohemia and Majorca, the dukes of Lorraine and Bourbon, the counts of Flanders, Aumale, Blois, Vaudemont, the archbishops of Nimes and Sens, and many other French lords and German barons, were slain. Froissart relates the singular fate of King John of Bohemia. Being old and blind, he ordered the bridle of his horse to be tied on each side to the horses of two cavaliers of his train, and thus guided, charged into the battle, where he fell, together with his attendants. His crest, consisting of 3 ostrich feathers, with the motto *Ich dien* (I serve), was, according to the custom of chivalry, adopted by the Black Prince, and is still the crest of the prince of Wales. The English loss was, comparatively small. In brief, this battle broke, for a time, the power of France, and enabled the English in the following year to become masters of Calais.

CREDI, Lorenzo, a Florentine artist, born about 1453, died about 1536. He was a fellow pupil of Leonardo da Vinci in the school of Verocchio, and so closely followed his style that some of his copies of Leonardo's works are scarcely to be distinguished from the originals. His "Holy Families," of which he painted a great number for private collections, are gracefully designed and highly finished. His most esteemed works are a "Madonna and Child with Saints Julian and Nicholas," now in the Louvre, and the "Birth of Christ," at Florence.

CRÉDIT MOBILIER, a joint stock company founded in Paris, upon the principle of limited liability, under the sanction of the government, by a decree dated Nov. 18, 1852, with a capital of 60,000,000 francs, divided into shares of 500 francs, payable to bearer, for the transaction of general banking business, and with the professed object of aiding the progress of public works, of promoting the development of national industry, and of consolidating into a common stock the shares and bonds of trading compa-

nies. According to M. Isaac Péreire, one of the original founders of the company, "it is to play, with respect to the fixed capital employed in industry, a part analogous to that which banks of discount fill with respect to its circulating capital." It is authorized to subscribe for or to acquire public securities as well as shares and bonds in industrial enterprises, particularly railways, canals, mines, and other public works; to issue its own bonds for an amount equal to its subscriptions and purchases, and, after the complete issue of the original capital of 60,000,000 francs, to issue its bonds equal to 10 times this amount, *i. e.* to 600,000,000 francs. By the terms of its charter, the company has unlimited power to engage in the most extensive operations, the only restriction being not to sell in advance public securities, nor to buy them on time. The following was the status of the company on Dec. 31, 1857:

ASSETS.

	Francs.
Rents, debentures, railway and other shares	83,063,991 41
Investment in various securities, continuations and advances on shares, debentures, &c.	49,841,450 12
Premises and furniture	1,449,436 50
Balance on hand and dividends due, Dec. 31, 1857	7,261,925 28
Total	141,616,803 31

LIABILITIES.

	Francs.
Capital	60,000,000 00
Deposits, current accounts	68,546,431 62
Bills payable, and sundries	3,911,264 65
Interest and dividends	3,025,373 75
Reserve fund	2,000,000 00
Balance of profit and loss account	4,133,733 29
Total	141,616,803 31

Showing a decrease in operations of about 40,000,000 francs compared to Dec. 31, 1856, and of about 50,000,000 francs compared to Dec. 31, 1855. The net profits of the company show considerable fluctuations. They were, in 1853, 3,500,000 francs; 1854, 9,800,000; 1855, about 28,000,000; 1856, about 15,000,000; and in 1857, only 4,133,733 29. M. Péreire, in his financial statement of Dec. 31, 1857, attributes the unfavorable result of 1857 mainly to the financial crisis, and the violent fall of the Crédit Mobilier shares at the beginning of 1858 to the attempt upon the emperor's life.—Among the most famous enterprises of the Crédit Mobilier, from the time of its foundation, may be mentioned the consolidation of the Paris gas and omnibus companies; the creation of the company of the *grand hôtel du Louvre* in the rue de Rivoli, and of the maritime company of clippers; the immense operations in railways in Spain, Russia, Switzerland, and Austria; loans to an aggregate amount of about 1,500,000,000 francs to French railway companies; and various other colossal transactions. By one of the most eloquent opponents of the company, M. Berryer, it has been characterized as "the greatest gambling house which the world has ever seen."—Prominent among the continental institutions which, with some modifications, have been formed after the model of the Crédit Mobilier, is that of Geneva, founded with the assistance of that of Paris in 1853, and that of Vienna, established in the early part of 1856. The Germans have been most active in founding similar companies, and not less than 3 books on that established at Vienna were published in 1857, and another book in the same year on that founded in Leipsic in 1856.

CREEKS, or MUSKOGEES, a southern tribe of North American Indians, now established in the Indian territory, who occupied prior to their removal the territory S. of the Alleghanies and S. W. of the Savannah, including the whole of the present state of Georgia and the greater part of Alabama. The Muskogee tradition, of immemorial antiquity, is that a long time ago some strange wandering clans of Indians from the northwest found their way down into Florida, into what was afterward known as the country of the Seminoles. Meeting with plenty of game, they established themselves there in the vicinity of the powerful Appalachian tribes, by whom they were styled Seminoles, signifying wanderers or lost men. Increasing in numbers and power, they excited the jealousy of their neighbors; wars ensued, and finally the Seminoles became masters of the country. The game of the region in process of time became insufficient, and emigrations followed. They spread northeastward almost to Cape Fear, and westward as far as the Tallapoosa and Coosa rivers, branches of the Alabama, where they were encountered by the powerful Alabama nation. They gained the friendship of this tribe, and incorporated it into their own body. They now distinguished themselves from their ancestors, the Seminoles, by the name of Muskogees, the English name of Creeks being afterward given them from the character of much of the country in which they were found. Other accounts make the Seminoles to have wandered from the Muskogees, who were settled in the country N. of Florida. Though spread over a fourfold wider territory than the Choctaws, they did not surpass them in population, their fighting men numbering about 4,000. They were famed as brave warriors, and extended their power and importance rather by the union of subject tribes than by increase of their original stock. By a liberal and protective policy long exercised toward vanquished and declining tribes, they encouraged their incorporation with themselves. The Alabamas and Coosades were the first who adopted the ceremonies and customs of the Creeks, and became part of the nation. The Natchez, or Sunset Indians, from the Mississippi, united with them some time prior to the revolution, after being driven out of Louisiana. Subsequently the Shawanese joined them in large numbers. The confederacy was divided into the upper and lower Creeks, the former having their principal seat upon the head waters of the Alabama, the latter near the junction of the tributaries which form the Appalachicola. In 1705, the Creeks aided the English Carolinians against the Spaniards of Florida. In

1715 they supported the Yamassees in the attack upon South Carolina, which was defeated by the efficient conduct of Gov. Craven. In 1721 the Savannah was fixed as their eastern boundary, though they permitted the English to maintain a post on the Altamaha. In 1733 Oglethorpe met them on the bluff of Yamacraw, on the Savannah, and they agreed in formal council to yield to the colonists all the lands below tide water between the Savannah and the Altamaha, except 3 islands on the coast. Six years later Oglethorpe again visited them at Cowetas, on the Chattahoochee, and by a new treaty they acknowledged themselves subject to the king of Great Britain, ceded to the English, with some reservations, the coast from the Savannah to the St. John's as far into the interior as the tide flows, and were confirmed in the possession of the rest of the territory between those rivers and between the sea and the mountains. During the war of the American revolution, the Creeks adhered to the British. After the conclusion of peace, the Georgians claimed that by treaties concluded in 1783, 1785, and 1786, this tribe had ceded to that state a considerable tract of their lands W. and S. of the Oconee. The Creeks, having an able chief in M'Gillivray, whose father was a Scotchman, denied the validity of these treaties, and, though they had always been allies of the English colonists against the Spaniards, now entered into close relations with the Spanish government of Florida. This was the period of their greatest power, when they numbered 6,000 warriors. British gunsmiths had long resided among them, so that they were well supplied with arms, which they could skilfully employ. In 1787 war broke out between them and the Georgians, who suffered severely. In 1789 they first entered into negotiations with the United States, and were disposed to acknowledge the president as their "great father" instead of the British king, but abruptly broke off the conference when they found that the commissioner did not propose to restore their lands. Mutual depredations prevailed on the frontier between the Creeks and Georgians, till the boundaries were settled by a treaty in 1796, according to which the tribe was to receive an annuity of $6,000, and to be provided with 2 blacksmiths, in exchange for permitting certain posts and trading houses in their territory. They had of late years made some progress in civilization, and, though still for the most part hunters, cultivated corn and sweet potatoes, and had a few slaves. In 1813 the example of Tecumseh, who visited them, excited them anew to war. Young men began "to dance the dance of the Indians of the lakes," and old men regretted and wished to revive the original savage simplicity of the nation. The upper Creeks especially betrayed a hostile disposition, and had long caused apprehensions on the part of the whites in Alabama and Georgia. On Aug. 30, 1813, Weatherford, a half-breed chief, at the head of 1,500 warriors, surprised Fort Mimms on the Alabama, and but 17 persons out of a garrison of 275 survived the carnage. Four invading columns, amounting to more than 7,000 men, were speedily organized in Tennessee, Georgia, and the Mississippi territory, to avenge the massacre. Gen. Jackson, the first in the field, captured 2 villages (Oct. 28 and Nov. 2) in the "hickory ground" between the Coosa and the Tallapoosa, in the latter of which no quarter was given. On Nov. 9 the savages were again defeated by him with great loss at Talladega, and soon after they were successively routed by each of the other 3 invading forces, which, however, failed to meet in the heart of the Creek country. In Jan. 1814, the fiercest party of the savages, called Red Sticks, attacked Gen. Jackson on his march, and obliged him to fall back to Fort Strother, from which he had advanced. He soon after received reenforcements, attacked on March 24 the main body of the Red Sticks at the great bend (also called the great horse-shoe) of the Tallapoosa, and ended the Creek war by a defeat and massacre from which not more than 20 warriors were believed to have escaped. A treaty was concluded on Aug. 9, by which the Creeks surrendered a large part of their finest territory. In 1818 they made 2 large additional cessions, for which they received $20,000 down, and an annuity of $10,000 for 10 years; and in that year they joined Gen. Jackson in the campaign against the Seminoles. On Feb. 12, 1825, they ceded all their lands in Georgia; but corruption being proved on the part of their agent, M'Intosh, he lost his life and the treaty was abrogated. By a new treaty, Jan. 24, 1826, they ceded all their lands in Georgia E. of the Chattahoochee, and on Nov. 15, 1827, all their remaining lands within the actual limits of Georgia. On March 2, 1832, they ceded all their lands E. of the Mississippi, and agreed to emigrate at the option of the United States. On Feb. 14, 1833, the federal government fixed their boundaries in the Indian territory, and agreed to patent their lands, in fee simple, during their existence as a nation and occupancy of them. Under this arrangement they have been removed. They occupy a fine country, next N. of the Choctaws and Chickasaws, on the northern side of the Canadian river. They have entirely abandoned the chase, and devote themselves to the cultivation of the soil and the raising of stock, the latter being a profitable pursuit. Few are engaged in trade or indicate any aptitude for the mechanic arts. They retain more of the government by hereditary chieftainship and circles than any other of the transferred tribes, and in their new locality are still divided into upper and lower Creeks. They have a written constitution; and the members of their council, which has an annual session, and their principal chief, are elected by the free citizens. They are owners of slaves, and are said to owe to them much of their advancement in agriculture. By the census of 1856, the entire tribe numbered

14,888, showing a great decrease during the preceding 20 years, their aggregate in 1833 having been 22,664, exclusive of about 1,000 slaves. There is a fund of $200,742, held in trust by the United States for the benefit of Creek orphans.

CREEPER, a bird of the order *passeres*, tribe *tenuirostres*, and family *certhidæ;* to the subfamily *certhinæ*, containing 5 genera, and to the genus *certhia* (Linn.), belongs our common brown creeper (*C. familiaris*, Linn.). The bill is moderate, slender, curved, with compressed sides and acute tip; the wings are moderate and rounded; the tail long and graduated, with the ends of the feathers rigid and acute; tarsi shorter than the middle toe; all the toes long and slender, with curved and sharp claws. There are 2 species, one inhabiting Asia, and the other Europe and North America; those who consider the American bird different, because found here, without being able to give any specific characters for it, may call our bird *C. Americana* (Pr. Bonap.). The creepers are found wherever trees are thick, climbing up the trunks with the aid of the tail, running along and on the under surface of branches in search of insects concealed in the bark. The upper parts of our species are reddish brown, the head darker, the rump lighter; all the feathers have a central dull whitish streak; wings deep brown, the coverts tipped with dull yellow, and the secondaries barred with the same; lower parts and band over eye silvery white; sides tinged with brown; webs of the quills, except of the outer three, crossed with a dull yellowish band; tail yellowish brown; length of bird 5½ inches, extent of wings 8½; the female is smaller and darker. It is extensively distributed over this country, alighting on all kinds of trees, preferring the tallest, in company with the smaller woodpeckers and nut-hatches. It breeds in holes in trees, often taking the abandoned nests of woodpeckers and squirrels; the eggs are 6 to 8, of a yellowish white color, with irregular purplish dots, especially at the larger end. It feeds on ants, larvæ, small insects, and particles of lichens, in the winter coming into the orchards near houses. It is an exceedingly active and restless bird, shooting down from the top of an examined tree to the base of another, which it ascends as before. To the same family belong the tree-creepers (*dendrocolaptinæ*), larger birds, with long curved bills, peculiar to South America; their habits are the same as those of the genus *certhia*. The black and white creeper is the *mniotilta varia* (Lath.), of the family *luscinidæ*.

CREFELD (Ger. *Krefeld*), a flourishing town of Rhenish Prussia, the principal seat of silk manufacture in Prussia, connected by railway with Cologne and Düsseldorf, 12 m. from the latter city; pop. about 40,000. Its most important public edifices are a Roman Catholic church, 2 Protestant churches, a synagogue, an orphan asylum, and a deaf and dumb institution. The silk manufacture was introduced in the 17th century by a colony of Huguenot refugees. It employs about 2,500 looms in the town and its vicinity; and the annual products are estimated at $5,000,000. There are also manufactories of woollen, cotton, and linen fabrics in Crefeld, as well as potteries, tanneries, and distilleries. It was formerly a place of considerable strength, and its walls are still standing.

CREICHTON, John, an Irish soldier of fortune, born in the county of Donegal in 1648, died in 1733. He entered the horse guards of Charles II., and displayed great zeal and activity in the campaign of that corps against the Covenanters of Scotland. When James II. was succeeded on the throne by William III., he attempted to excite a rebellion, but was imprisoned at Edinburgh. After several years he was permitted to return to Ireland, where in his old age he met Swift, who was interested in his history, and urged him to write a narrative of his adventures. His "Memoirs," revised by Swift, appeared in 1731, and contain curious Scottish particulars relative to the reign of Charles II. and James II., and interesting notices of characters and events which served as materials for Sir Walter Scott in the composition of his "Old Mortality."

CREIGHTON, John Orde, a commodore in the U. S. navy, born in the city of New York, died at Sing Sing, March 18, 1846. He entered the navy as midshipman in June, 1800, and served under Commodore Preble before Tripoli. In 1807 he became a lieutenant, and was attached to the frigate Chesapeake in June of that year, when she fought the British ship Leopard. He was afterward attached to the frigate President, and was first lieutenant of that ship in her action with the British ship of war Little Belt, May 16, 1811. In 1813 he commanded the brig Rattlesnake, was promoted to the rank of master commandant in that year, and to that of captain the year following. In 1829–'30 he commanded the squadron on the coast of Brazil.

CRELL, or Crellius, Johann, a theologian of the school of Faustus Socinus, born near Nuremberg in 1590, died in Cracow, June 11, 1633. He removed to Poland in 1612, and officiated at Cracow as rector of the Unitarian divinity school, and afterward as preacher. He made some valuable contributions to theological literature, among others a German translation of the New Testament. He also wrote a reply to Grotius's *De Satisfactione Christi*.—There were 2 other Socinian theologians of the same name: Christoph, who died Dec. 12, 1680, and his son Samuel, born in 1657, died June 9, 1747.

CRELL, Nikolaus, prime minister of Christian I., elector of Saxony, born in Leipsic about 1550, beheaded at Dresden, Oct. 9, 1601. Anticipating great danger to the cause of the reformation from the sectarian conflicts among the Protestants, he recommended an approximation to Calvinism (Crypto-Calvinism), with a view of putting an end to their conflicts and of presenting a united front against the Roman Catholics; but by order of Christian's successor, the intolerant regent Frederic William, he was doomed to 10 years' imprisonment and finally put to death.

CREMA, a town of Lombardy, in the province of Lodi-Crema, on the Serio, 25 m. E. of Milan; pop. about 9,000. It is well built and fortified, and has several handsome churches and palaces, as well as manufactories of lace, hats, thread, and silk. Crema was founded in the 6th century by some fugitives whom the oppressions of Alboin, the first Lombard king of Italy, had driven from their homes. During the wars of the Guelphs and Ghibellines it was destroyed by Frederic I., but was afterward rebuilt. In 1797 it was captured by the French.

CREMERA, now Aqua Traversa, a small river of Etruria which falls into the Tiber, a short distance above Rome. On the banks of this river the 300 Fabii encamped, when, after marching from Rome, they undertook to wage war against Veii, and here they were surprised by their enemies, and cut off, 477 B. C.

CRÉMIEUX, Isaac Adolphe, French minister of justice in 1848, born of Jewish parents at Nimes, April 10, 1796, studied law at Aix, and was admitted to the bar of his native town in 1817. His success there established his reputation at Paris, where, however, he was not fortunate in his first important forensic effort as counsel for Guernon-Ranville, a minister of Charles X., who had been arraigned as one of the authors of the fatal ordinances of July, 1830. Overcome by the excitement of the occasion he fainted, and was unable to continue the defence. But he soon regained his prestige in the courts, and after having purchased from Odilon Barrot his office and function as advocate, he defended Armand Marrast, Raspail, and other eminent republicans prosecuted by the government, with great ability before the court of appeal. In 1842 he took his seat in the chamber of deputies on the extreme left as deputy from Chinon. He opposed the game laws, supported free trade principles, and by his systematic attacks on the policy of the government contributed not a little to pave the way for the revolution of 1848. When this at last broke out, he told Louis Philippe and his queen, whom on the day of their flight he met in the place de la Concorde, that there was no hope left, and recommended them to leave France immediately. He then proceeded to the chamber of deputies, inclined to support the regency of the duchess of Orleans; but when this was rejected, he proposed a provisional government, of which he became a member, the ministry of justice being intrusted to his charge. On June 7, 1848, he left the government in consequence of a prosecution against his friend Louis Blanc, but remained as a member of the constituent assembly. On Dec. 10, 1848, he voted for Louis Napoleon's election to the presidency, without however ceasing to advocate in the legislative assembly the views of the extreme republican party. When the day of the *coup d'état* came (Dec. 2, 1851), he was arrested, but soon released; he has since resumed his practice as a lawyer. His appearance is unprepossessing, but his eloquence is remarkable and full of oriental vivacity. He is wealthy and hospitable. His *salon* is a favorite resort of musicians, he being himself a great amateur. He is also distinguished as a zealous defender of his Jewish brethren, among whom he earned great popularity by accompanying Sir Moses Montefiore to the East in behalf of the persecuted Jews of Damascus in 1840.

CREMNITZ. See Kremnitz.

CREMONA, a province of the Austrian crownland of Lombardy, bounded N. by the provinces of Brescia and Bergamo, E. by Mantua, S. by the Po, and W. by the Adda. Its greatest length is about 45 m., its breadth about 15 m. Area, 523 sq. m.; pop. about 200,000. The principal products are flax, wine, oil, cattle, and horses. It produces wine to the extent of about 2,000,000 gallons annually. Silk is the most important manufacture. The province formed part of the duchy of Milan until 1800, when, conquered by the French, it constituted the eastern part of the department of Alto-Po until 1814, when it came into possession of Austria. It is divided into 9 districts and 186 communes; contains 11 small towns and 162 villages.—Cremona, the capital, pop. about 37,000, 45 m. from Milan, contains 45 churches, of which the cathedral is the most remarkable, rivalling, in the opinion of Lanzi, the pictorial magnificence of the Sistine chapel, and containing many works of art. The greatest architectural celebrity, however, of Cremona is the Torazzo, or belfry tower, ending in a spire, the highest of all the towers in N. Italy, reaching the elevation of nearly 400 feet, with about 500 steps to ascend to its summit. There are also many sumptuous palaces, with fine picture galleries, and a *campo santo*, now used as the repository of the archives, which contains an underground vault and a curious mosaic pavement. Cremona is the seat of a bishop, of the provincial authorities, and courts of law; contains a citadel, a gymnasium, a lyceum, an academy of fine arts, infant schools (founded here in 1829, previous to their establishment in any other Italian town), and schools opened at certain hours on Sundays and other holy days. It carries on an extensive trade by means of the Po, and the various canals communicating with that river. Cremona was a Roman colony, founded in 219 B. C.; it was often attacked by hostile Gallic tribes, and was destroyed by them in 193. In A. D. 69 it was plundered and burned by the troops of Vespasian, who subsequently rebuilt it. In later periods it was often conquered, and had many misfortunes; last of all in 1849, when it was bombarded by the Austrians.—Cremona is the general name applied to the violins made at Cremona, by the Amati family and Stradivarius, in the 17th and 18th centuries. They excel all others in purity of tone, and bring enormous prices. The name is also erroneously given to a stop in the organ which is intended to imitate the krumhorn, a species of cornet.

CRENIC ACID, Crenates (Gr. κρηνη, a

spring or fountain), an acid and its compounds, so named by Berzelius from having been first found by him in spring water, being among the products of vegetable decomposition, and constituents of humus. This acid and the apocrenic acid associated with it differ from the extract of mould or geine of Berzelius in containing nitrogen. Liebig, Graham, and other distinguished chemists, do not recognize the existence of this substance. The following description is given of it as obtained by Berzelius: a sour, yellow mass, reddening litmus, soluble in water and alcohol; forming salts (crenates) with bases, which salts are soluble in water, but not in alcohol; obtained from ochreous sediments, by boiling with caustic potash, saturating with acetic acid, and precipitating with acetate of copper the crenic acid as a crenate of copper. This is decomposed by sulphuretted hydrogen, and purified by washing with alcohol. Its formula is given as $C_{24}H_{12}O_{16}$, or $C_7H_8NO_6$.

CREOLE, a corruption of the Spanish word *criollo*, which signifies one born in America or the West Indies, of European ancestors. In this sense, all the native white people of the United States are creoles. But the word in its English use has undergone both a limitation and an extension. It is limited to persons born within or near the tropics; and it is made to include persons of all colors. Thus the term creole negro is employed in the English West Indies to distinguish the negroes born there from the Africans imported during the time of the slave trade. The application of this term to the colored people has led to an idea common in some parts of the United States, though wholly unfounded, that it implies an admixture, greater or less, of African blood. The creoles of the West Indies and the adjacent coasts of the continent are distinguished by marked physical peculiarities from their European ancestors. Bryan Edwards, who had ample opportunities for observation, and who is a very competent observer, describes them, in his "History of the West Indies," as obviously a taller race on the whole than the European, but in general not proportionately robust. He had known several who were full 6 feet 4 inches in height, but they wanted bulk to come up to the idea of masculine beauty. This peculiarity, however, it is to be observed, is not confined to the creoles of the tropics. The same remark has been made respecting the descendants of Europeans born in the United States and in Australia. The creoles are distinguished (and this is an exclusive peculiarity of them) for the freedom and suppleness of their joints, which enables them to move with great ease, agility, and grace. From the same cause they excel in penmanship, and in every thing requiring flexibility of movement. The effect of climate is likewise obvious in the structure of the eye, the socket being considerably deeper than among Europeans, thus affording a protection against the glare of the sun. Their skin feels considerably colder than that of Europeans—a circumstance observed in a still stronger degree of the negroes, and going to show an effort of nature to protect their bodies against the heat. Even though living in the same way with Europeans, they are rarely subject to those inflammatory disorders, the yellow fever included, which prove so often fatal to the former. This is particularly true of the creole women of the West Indies, who live in general very quiet and regular lives, and who in their diet are abstemious even perhaps to a fault. Simple water or lemonade is the strongest beverage in which they indulge, and a vegetable mess at noon, seasoned with Cayenne pepper, constitutes their principal meal. To a stranger newly arrived, they appear as if just risen from a sick bed. Their voices are soft and spiritless, every step betrays languor, while their cheeks lack entirely the bloom of the rose. They have, however, in general beautiful black hair, and the finest eyes of any women in the world—large, languishing, and expressive. They are also noted for their fine teeth. The early display of mental powers in young creole children, and their superiority in this respect over European children of the same age, has been noted by all travellers. It is difficult, however, to rear white children in that climate; though perhaps the difficulty arises in no small degree from the mode of living indulged in.. The peculiarities of the white creole are to be found also in the mixed race, with more of force and vivacity on the part of the latter, the women especially, as being less enervated by the climate. A high degree of tenderness and compassion, and great adhesiveness of affection, characterize the creole women of all colors. There may be observed also a marked distinction between the creole negroes and those imported from Africa. The former are more slender, agile, and graceful, though not less strong or capable of labor, with quicker perceptions and more volatile dispositions. If the white race deteriorates by its transfer to the West Indies, the black race evidently improves physically as well as mentally. How far the native-born whites of the high tropical tablelands of Mexico and South America resemble or differ from the white natives of the lower and hotter regions, no traveller seems yet to have accurately noted.

CREON. I. A mythical king of Corinth, in whose reign Jason returned to Greece with the sorceress Medea. Visiting Corinth on his way home, the hero beheld the beautiful Creüsa, the only daughter of the king, and became enamored of her. Creon promised to give her to him in marriage if he would divorce Medea. Jason consented to do so, and the king at once ordered Medea to quit his dominions. The sorceress begged to be allowed to remain for a single day, and when this request was granted she prepared in the interval a magical robe, which she sent as a present to Creüsa, who, unconscious of danger, put it on, and was burned to death. Creon, who had kissed her while in the agony of death, also caught fire and perished.

II. A king of Thebes, who, alarmed by the ravages of the Sphinx, offered his crown and his sister Jocasta to any one that could solve the enigma propounded by the monster. Œdipus, having succeeded in doing so, ascended the throne and married Jocasta, not knowing that she was his mother. The fruit of this marriage was 2 sons, Eteocles and Polynices, who, after their father's death, having long been at enmity, finally slew each other in single combat. Creon, now resuming the government, ordained that Polynices should remain unburied, and that any who infringed this decree should be buried alive. Antigone, sister of Polynices, buried her brother in disregard of this edict, and was imprisoned in a cave. Here she instantly killed herself, whereon Hæmon, her lover, rushed to her prison-house, and slew himself on her corse.

CREOSOTE, an oily, colorless liquid, of a burning and bitter taste, and a peculiar smoky odor. It was first obtained by Dr. von Reichenbach, in 1830, among the products of the distillation of wood, and named from the Greek κρεας, flesh, and σωζω, to preserve, in reference to its peculiar antiseptic properties. It possesses neither acid nor alkaline reaction. It boils at the temperature of 397°, and does not freeze at 17° below zero. At 68° its specific gravity is 1.037. It evaporates without residue, leaving upon paper a temporary greasy stain, and upon the skin a white spot. In concentrated form it acts as a caustic. It may be inflamed from a candle, and then burns with much smoke. It is but partially soluble in water, but is itself a powerful solvent of the resins, fats, indigo, camphor, &c. Its composition is variously stated. According to Ettling it consists of carbon 77.42, hydrogen 8.12, and oxygen 14.46. Its most remarkable quality is that for which it was named. Meats are preserved by soaking them in a dilute solution of creosote for a quarter of an hour, and then draining off the water and drying. Hams and tongues acquire a very delicate flavor after being immersed for 24 hours in a mixture of 1 part of pure creosote with 100 of water or brine. A process has been patented in England for impregnating salt with the volatile products of wood tar; meats prepared with it are both smoked and salted. It is the creosote in pyroligneous acid and in the smoke from wood that gives to these the property of curing meat. Either crude pyroligneous acid or wood tar may be used to furnish creosote. The liquid distilled off the latter divides into 3 layers, the lowest containing the creosote. The acetic acid also present in it is removed, after separating this layer from the other, by means of carbonate of potash. The oil which after some time collects upon the liquid is distilled, producing a heavy liquid, with other lighter fluids. The latter is agitated with phosphoric acid, and again distilled to remove ammonia. It is then mixed with solution of caustic potash of specific gravity 1.12, which dissolves the creosote, but leaves the eupione insoluble. This is decanted off. The liquid is then left for some time exposed to the air till it acquires a brown color. Sulphuric acid is then added, which sets the creosote free, so that it may be decanted; but it requires to be again treated with caustic potash and sulphuric acid, and the process repeated until the creosote, on exposure for some time to the air, ceases to turn brown. It still requires, after thorough washing with water, to be distilled from hydrate of potash, or from a strong solution of caustic potash. The first portions that come over are water, and are rejected. Creosote is known to be impure by turning brown on exposure to the air; strong acetic acid also detects its usual impurities, dissolving with the creosote, and leaving them floating on the surface. As a medicine, creosote has been much used, both as an external application and in doses inwardly administered. It is introduced into ointments and applied to wounds, burns, ulcers, and scaly eruptions. It checks hemorrhage, nausea, and vomiting, and applied to an aching tooth, often instantly relieves the pain. It has been successfully given in diarrhœa, cholera morbus, cholera infantum, &c.; indeed, there is hardly a substance in materia medica that has been administered to such a great variety of diseases, and, in many of them, with such decidedly favorable results. In an overdose it is a poison, and no antidote is known; emetics and stimulants are the only treatment. A few drops of creosote added to a pint of ink will prevent mouldiness.

CRESCENDO, in music, an Italian term signifying that the notes over which it is placed are to be gradually swelled. It is common to designate it by the following sign <.

CRESCENT (Lat. *crescere*, to increase), originally an epithet applied to the moon in its first quarter, when its disk is enlarging and its horns are acute. Any figure or likeness of the new moon was afterward termed a crescent, which became a favorite form for ornaments. The Syrian Astarte and the Greek Artemis were often represented with it placed horizontally over their brows, having its horns turned upward. An ivory crescent was worn as a sort of buckle for the cothurnus by wealthy Athenians, and Roman matrons enlarged it as a decoration for the hair. Throughout antiquity the crescent was especially a Byzantine symbol, and it appears on Byzantine imperial medals from the time of Augustus. When the Turks became masters of Constantinople they adopted this symbol, inscribed it upon their standards, banners, and mosques, and named their dominion the empire of the crescent.—In 1448 a military order of the crescent was instituted by René of Anjou. It was composed of 50 noble knights, each of whom wore an enamelled crescent on the right arm, from which was suspended a number of small wooden columns equal to that of the combats in which he had been engaged. In 1799, after the battle of the Nile, the sultan Selim III. presented to Nelson a splendid cres-

cent adorned with diamonds. It became a favorite ornament of the English admiral, who often declared himself a knight of the crescent. This circumstance induced the sultan to found in 1801 the order of the crescent, to be conferred as an honor upon foreigners who had deserved well of Turkey.

CRESCENTINI, Girolamo, a masculine soprano singer, born near Urbino, Italy, in 1769, died at Naples in 1846. He was received with the utmost enthusiasm all over Europe, especially in Vienna. He was a great favorite with Napoleon I., who engaged him for his private chapel in Paris in 1806; but subsequently he returned to Naples, where he taught music with great success, and published collections of exercises in musical vocalization.

CRESCENZI, Pietro de', a Bolognese nobleman, born about 1230, died in 1320, the author of the most valuable work on agriculture of the middle ages, entitled *Opus Ruralium Commodorum*, which contained not only the personal experiences and observations of the author, but the best information that could be gained from the agriculturists of antiquity. It has been translated into several modern languages, and the best Latin edition is that of Gessner, 2 vols., Leipsic, 1735.

CRESPEL-DELLISSE, Louis François Xavier Joseph, a French scientific agriculturist, born in Lille, March 22, 1789, established the first important manufactory of beet-root sugar in his native city, in 1810, in concert with Messrs. Dellisse and Passy. Subsequently he founded nearly 20 agricultural establishments in various parts of France, of which he made his refinery at Arras the centre.

CRESS, the name of several species of plants, with acrid or pungent leaves, most of which belong to the natural order *cruciferæ*. The water cresses (*nasturtium* and *sisymbrium*) are the most common varieties. They grow abundantly on the brinks of rivulets and small ponds, may be eaten as a salad, and are valued as antiscorbutic medicines.

CRESSON, Elliott, an American philanthropist, born March 2, 1796, died Feb. 20, 1854. He was a successful merchant in Philadelphia, where he resided all his life, and a member of the society of Friends. His benevolent disposition was especially turned toward the Indian and negro population of the United States. At one time he proposed to become a missionary among the Seminoles of Florida, and afterward engaged in establishing the first African colony of liberated slaves in the territory of Bassa Cove. In the winter of 1838–'39 he made the tour of the New England states as agent of the national colonization society, and the next winter was spent in a similar mission in the southern states. He everywhere recommended his measures with the eloquence of sincere conviction, and met with much favor and success. He sailed to England in Dec. 1840, where he spent 2 years in advocating the project of colonization, as also 3 years from 1850 to 1853. His time and labor were contributed without pay, and by his will he distributed his estate to a great variety of charities. He bequeathed in this way an amount of $122,000, mostly to institutions already established, but a bequest of a landed estate of over $30,000 was to establish a home for aged, infirm, or invalid merchants or gentlemen, who may have become unable to procure the comforts appropriate to their condition in life.

CRESSY. See Crécy.

CREST (Lat. *crista*), originally the reddish caruncle and tuft of feathers which rise on the heads of some birds, as the cock. It also designates the plume or other ornament worn by warriors and cavaliers on the top of the helmet or casque. By Herodotus the invention of martial crests is attributed to the Carians, whose painted bucklers, and casques mounted with feathers, gained them the appellation of cocks. The crests of the Homeric heroes were often bunches of horse hair, and both the Greeks and Romans esteemed the capture of an enemy's crest an honorable feat of war. Crests, made of the feathers of the ostrich or heron, or of painted wood or parchment, were worn by knights at mediæval jousts and tournaments. When the shield was not borne, they afforded the principal criterion of nobility.

CRESWICK, Thomas, an English landscape painter, born at Sheffield, Yorkshire, in 1811. His first pictures, consisting of views in North Wales and Derbyshire, were exhibited at the royal academy in 1828. His pictures are generally elaborate, with admirably pencilled foliage and atmospheric effects, and a precision of drawing never degenerating into stiffness. He was elected an associate of the royal academy in 1842, and an academician in 1851. His pencil is discernible in several recent illustrated works.

CRETACEOUS GROUP (Lat. *creta*, chalk), a series of stratified rocks forming the upper division of the secondary formation, distinguished as containing the last strata of which the fossil animal remains are wholly of extinct species. The group is subdivided into upper and lower; the former is often called from its principal member the chalk, and the latter for the same reason the greensand. The group underlies the tertiary beds of the London and Paris basins, rising up toward the straits of Dover on each side, along the coast of which its white chalk cliffs form prominent objects in the scenery. The formation is represented in New Jersey by beds of yellowish limestone and of greensand, which contain fossil shells, some of which belong to the same species, and most of them to the same genera, with those found in the cretaceous rocks of Europe. The same genera of fish also are common to the group of the two countries. The formation is traced through the eastern part of North Carolina and central part of Georgia, and after sweeping round the southern termination of the Alleghanies in Alabama passes through that state and Mississippi northward into Tennessee and Kentucky. It is recognized

near Council Bluff on the Missouri, in Texas, upon the Andes near Bogota, S. A., and also in Hindostan. Thus at widely separated points in the ancient seas of 4 continents were similar deposits produced during the same geological period, characterized by the animal remains they include, of the same general type, and often of the same species. For relations of this group to those which precede and succeed it, see GEOLOGY; and for further details regarding its members, see CHALK, GAULT, and GREENSAND.

CRETE. See CANDIA.

CRETINS (called in Carinthia, *Tockem;* in Styria, *Tosten;* in Austria, *Trotteln;* in the Tyrol, *Talken;* in Saltzburg, *Totteln;* in Würtemberg, *Fexen;* in Sardinia and some other countries, *Lallen;* and in many portions of Germany, *Gescheipf*), persons in whom partial or complete idiocy is combined with great bodily deformity. The most vivid and accurate description of their appearance is that given by Berchtold Beaupié in his *Dissertation sur les Cretins:* "Who is this melancholy being who bears the human form in its lowest and most repulsive expression? I see a head of unusual form and size, a squat and bloated figure, with a stupid look, with blear, hollow, and heavy eyes, with thick projecting eyelids, and a flat nose. His face is of a leaden hue, his skin is dirty, flabby, covered with tetters, and his thick tongue hangs down over his moist livid lips. His mouth, always open and full of saliva, shows teeth which are going to decay. His chest is narrow, his back curved, his breath asthmatic. I see indeed arms and legs, but his limbs are short, misshapen, lean, stiff, without power and without utility. The knees are thick and inclined inward, and the feet flat. The large head drops listlessly on the breast, the belly resembles a bag, and the integuments are so loose that they cannot retain the intestines in its cavity. This loathsome idiotic being hears not, speaks not, and only now and then utters a hoarse, wild, inarticulate sound. Notwithstanding his greediness, he is scarcely able to support life. One passion alone seems sometimes to rouse him from his usual insensibility; it is the sexual instinct in its rudest brutality. At first we should be inclined to take this being for a gigantic polypus, something in imitation of a man, for it scarcely moves; it creeps with the painful heaviness of a sloth; and yet it is the monarch of the earth, but dethroned and degraded. It is a cretin." The name cretin is of uncertain origin; Viréy derives it from *Chrétien*, Christian, because the inhabitants of the countries where cretinism prevails were very generally disposed to regard the cretins as incapable of sinfulness ("souls without sin," they call them), and hence regarded them as favored of God, or "good Christians." Blackie, however, whose essay on this subject gives evidence of very thorough research, derives it from the Romance or Grison *cretina*, a corruption of the Latin *creatura*, a creature. This unfortunate class are far more widely distributed than has been generally supposed. Throughout the whole sub-Alpine region in Europe, as well as in some of the more level regions, they are found, and often in great numbers. The goitre or bronchocele, so prevalent throughout the whole of the Alpine countries, is often accompanied by cretinism, and is, with very few exceptions, always found on the cretin. Switzerland, and especially the cantons Valais, Vaud, Uri, Aargau, Grisons, and Glarus, seems to be the home of this frightful deformity. It is endemic in portions of Rhenish Prussia, Baden, Sardinia, Bavaria, upper Austria, along the banks of the Danube, particularly in Judenburg, Bruck, Gratz, Marburg, and Cilly, in Würtemberg, Denmark, Norway, in the Alpine departments of France, in portions of Turkey and Russia, and in the highlands of Scotland. In Africa, it has been found prevalent along the northern slope of the Atlas range. In Asia, the districts around the base of the Himalaya range furnish great numbers of cases, as well as China, Chinese Tartary, and Sumatra. In South America, cretins are found in considerable numbers on the eastern or Atlantic slope of the Andes, and scattered cases occur along the Alleghany, Green mountain, and Hoosic ranges in the United States. In some parts of Canada cases have also been observed. The number of cretins in the sub-Alpine districts of Europe, whether considered actually or relatively to the population, is frightfully large. In some localities in Switzerland, Rhenish Prussia, and the Alpine districts of France and Savoy, the number is so great, that in whole villages not an able-bodied man can be found.—The causes of cretinism are involved in some obscurity, though within the past 20 years many of the ablest medical men in Europe have been investigating the subject with great care. The localities in which it is most prevalent in the Alpine districts are low-lying valleys, narrow, and exposed to the direct rays of the sun but for a few hours each day, and usually having but one outlet. In these, the air is often stagnant and the heat intense; the water is also in some cases charged with mineral impurities, especially the salts of lime; the food of the inhabitants is often scanty in quantity, and inferior in quality; they are in many cases grossly intemperate, and intermarriage with near relatives, and those affected with goitre or incipient cretinism, is common. In other countries it occurs on open plains, but in other respects under circumstances analogous to those already named. Whatever may be the obscurity in regard to the causes of this fearful disorder, there is none in regard to the indications to be fulfilled in its treatment. The life of the cretin is usually short; few are found above 30 years of age, and any treatment having in view the improvement of their health must, to be of benefit, be applied to the young. The recovery of a patient beyond the age of 12 years is almost hopeless. The first thing to be accomplished is the removal of the young cretin, as soon as possible after the disease exhibits itself (for in many of the cases cretinism is not developed till the period of dentition, and

sometimes even not until the 6th or 7th year), to a pure bracing atmosphere. It has been ascertained that on the Alps it seldom occurs at an elevation of 3,000 feet above the level of the sea, and never at the height of 4,000 feet. Hence, those who have attempted its treatment in Europe have preferred elevated locations. The treatment requires an abundance of pure water, for drinking, washing, and bathing; warm and cold baths and douches; friction of the skin with brushes and stimulating liquids, to rouse its action; warm clothing; gymnastic exercises of the simplest character, passing on to those more difficult and fatiguing as they can be borne; the administration of some of the mineral tonics; nourishing and abundant, but simple food; iodine in some form, cod-liver oil, and the administration of some of the phosphates to give more firmness to the bony structure. Galvanism and electro-magnetism are also of benefit. As the essential nature of the disease seems to be a combination of rachitis (rickets) with retarded mental development, the bodily treatment must resemble as far as possible that ordinarily adopted in the treatment of rachitis and other scrofulous affections. The effort to develop the mind must follow, and with considerable interval, the attempt to restore the body to a healthy condition. The method of training for this purpose is similar to that employed in the instruction of idiots. The measure of success has been somewhat greater than with idiots, partly perhaps from the fact that instruction has usually been commenced at an earlier period, and partly because the mental paralysis (if we may be allowed the expression) was less profound than in the case of the idiot. The idea of restoring the cretin to health and to the exercise of his mental faculties had occurred to several individuals, and had been made the topic of some essays in the early part of the present century, by Fodéré, Wenzel, Viréy, Abercrombie, and others; yet no systematic effort for the purpose was made till 1839, when Dr. Guggenbühl undertook the establishment of an institution for the care and cure of cretins. He located this institution on the Abendberg, in the canton of Bern, in 1840, and has devoted his life to the work of their training. That, like the good abbé de l'Épée, whom in many respects he resembles, his enthusiasm may at times have led him to regard the intellectual progress of his pupils as beyond what they had actually attained, and to mistake answers learned by rote for the results of mental activity, is very possible; but, granting all that his detractors say to be true, he has undoubtedly restored many of this abject and degraded class to intelligence, activity, and life. There are now 5 other institutions on the continent expressly for the treatment of cretins, aside from those intended for the instruction of idiots and imbeciles not affected with cretinism. They are Dr. Erlenmayer's at Bendorf, with 25 or 30 pupils; Dr. Zemmer's at Mareaburg, with about 60 pupils; Dr. Müller's at Winterbach, with about the same number; a small one at Ecksberg, in Bavaria; and another in the valley of Aosta, in Piedmont, occupying the old lepers' hospital at the monastery. These all owe their origin to the example of Dr. Guggenbühl, but they have hardly attained to his measure of success. Some of the idiot schools also admit a few cretins; but the entire provision for their instruction in Europe furnishes accommodation for not more than 250 children, while at the lowest estimate there are more than 50,000 cretins on the continent. Several of the smaller governments of Germany have, however, taken the preliminary steps for the organization of cretin hospitals.

CREUSE, a department of central France, traversed by the river Creuse, from which it derives its name, and by other streams, none of which are here navigable; area, 2,133 sq. m.; pop. in 1856, 278,889. It is very mountainous, and contains granite, coal, gypsum, and potters' clay. The soil is poor, except in the N. E. part; agriculture is backward; the climate is damp and changeable; and the domestic animals are of an inferior breed. The crops of grain are insufficient for domestic consumption. Fruit, rape seed, and hemp, however, are raised abundantly, and quantities of honey are collected. The chief manufactures are carpets, tapestry, coarse woollen goods, cotton, leather, paper, glass, and porcelain. There are no canals, but the department is traversed by a railway from Châteauroux to Limoges. It is divided into 4 arrondissements, 25 cantons, and 261 communes. Capital, Guéret.

CREUTZ, Gustaf Filip, count, a Swedish poet and diplomatist, born in Finland in 1726, died in 1785. His poems were published in 1795, including *Atis og Camilla*, a pastoral epic in 5 cantos. While Swedish ambassador to Paris, he concluded, April 3, 1783, a commercial treaty with Benjamin Franklin, as representative of the United States. On his return to Stockholm he was appointed minister of foreign affairs, and chancellor of the university of Upsal. Gustavus III. purchased his library, which is now in the palace of Haga, and on April 26, 1786, the king in person pronounced his eulogy, before a chapter of the Swedish order of the seraphim, of which Creutz was a member.

CREUZER, Georg Friedrich, a German philologist and antiquary, born at Marburg, March 10, 1771, died in Heidelberg, Feb. 16, 1858. He was the son of a bookbinder, commenced his studies in his native city, and completed them at the university of Jena. After his return to Marburg he was appointed to a professorship of Greek, and subsequently of rhetoric, poetry, and Greek literature, which, however, he soon gave up, having accepted in 1804 the professorship of philology and ancient literature at the university of Heidelberg. Here he remained industriously engaged as a teacher till 1845, and as an author to the end of his life. The philological seminary, which was founded at Heidelberg in 1807 according to his

plans, has since exercised a marked influence upon that branch of science in Germany. His literary fame rests chiefly on his "Symbolics and Mythology of the Ancient Nations, and particularly of the Greeks" (4 vols., Leipsic, 1810–'12; 3d edition, 4 vols., Leipsic and Darmstadt, 1837–'44). This work, which contends for a bold and mystical theory as to the extreme antiquity and oriental origin of the Greek mythological, or rather theological systems, drew upon the author a series of critical attacks from G. Hermann, J. H. Voss (in the "Letters on Homer and Hesiod," and in the letter to Creuzer "On the Essence and Treatment of Mythology"), Lobeck, and a host of minor writers. The most remarkable of his other publications are: the edition of Plotinus's *Opera Omnia* (3 vols., Oxford, 1835); those of Cicero's *De Natura Deorum*, *De Divinatione*, *De Legibus*, *De Republica*, &c., executed in conjunction with G. H. Moser; "Historical Art of the Greeks" (Leipsic, 1803); *Dionysus, seu Commentationes de Rerum Bacchicarum Originibus et Causis* (2 vols., Heidelberg, 1808); "Sketch of Roman Antiquities," (2d edition, 1829); "Contributions to the History and Antiquities of Rome" (1836; French, in the *Mémoires de l'institut royal*, 1840); "Contributions to the Gallery of Ancient Dramatists" (1839); his autobiographical works entitled "From the Life of an Old Professor" (1848), and "Paralipomena of the Life of an Old Professor" (1858); "Contributions to the History of Classical Philosophy" (1854). A collection of his "New and Corrected Works" (1837–'54) contains a new edition of his German writings. Several of his works have been translated into foreign languages.

CREUZNACH, a Prussian town and watering place in the district of Coblentz, picturesquely situated on the river Nahe, 8 m. from Bingen, pop. about 9,000, with extensive salt works in the neighborhood, and saline springs, which are chiefly used for the cure of scrofulous diseases. In the vicinity are the ruins of the castle of Ebernburg, destroyed by the French toward the end of the 17th century, in former times a place of refuge for Ulrich von Hutten, Melanchthon, and other friends of Franz von Sickingen, to whom it then belonged.

CREWE, a market town of Cheshire, England, 32 m. S. E. of Liverpool, and important as a diverging point of 5 lines of railway, leading to Manchester, Birmingham, Chester, and other large towns. Pop. in 1851, 4,491.

CRIBBAGE, a game at cards played by 2 persons with a full pack of 52 cards. The points constituting the game, 61 in number, are scored by pegs on a board perforated with the necessary number of holes, called the cribbage board. The advantage lies with the dealer, who makes up a 3d hand for himself, called the crib, partly out of the hand of his opponent, to offset which the latter at the commencement of the game is entitled to score 3 points. There is a variety of this game called 3-handed cribbage, played by 3 persons with a triangular board. Four-handed cribbage is played by 4 persons in partnership of 2 and 2, as in whist.

CRICHTON, James, commonly called the "admirable Crichton," born probably in the castle of Cluny, in Scotland, Aug. 19, 1560, died in Mantua, July 3, 1583. He was of high descent, his father being lord advocate of Scotland, and his mother being a Stuart of the lineage of the reigning family. He was educated in Perth, till at the age of 10 he was sent to the university of St. Andrew's, then reputed the first school of philosophy in Scotland. Aldus Manutius mentions Rutherford, Buchanan, Hepburn, and Robertson as eminent scholars who were his masters. His ardor in study and progress in knowledge were astonishing. In his 12th year he took the degree of bachelor of arts; in his 14th, that of master; and, though the youngest of all, he was then esteemed the third scholar in the university. Before his 17th year, according to the current narrative, he had mastered the whole circle of science, could speak and write 10 languages, had excellent skill in painting, drawing, riding, fencing, dancing, singing, and playing on musical instruments, and possessed extraordinary physical beauty, symmetry, and strength. He soon after repaired to Paris, and according to Sir Thomas Urquhart, who is supported by no other authority, immediately determined, in compliance with mediæval scholastic usage, to challenge the philosophers and scholars of the city to a public disputation. To this end he affixed placards to the gates of the different schools, halls, and colleges of the university, and to the pillars before the houses of men of learning, inviting all learned persons to meet him on that day 6 weeks, before 9 o'clock in the morning, at the college of Navarre, where he would "be ready to answer to what should be propounded to him concerning any science, liberal art, discipline, or faculty, practical or theoretic, not excluding the theological or jurisprudential habits, though grounded but upon the testimonies of God and man, and that in any of these 12 languages: Hebrew, Syriac, Arabic, Greek, Latin, Spanish, French, Italian, English, Dutch, Flemish, and Slavonian, in either prose or verse, at the discretion of the disputant." The interval he passed in hawking, hunting, tilting, throwing the lance, games of chance, and other amusements of the gay city, provoking the satire of the students by his nonchalance; but on the appointed day he encountered the gravest philosophers and divines in presence of over 3,000 auditors, acquitted himself with marvellous learning during a disputation of 9 hours with the most eminent doctors, and was presented by the rector amid the acclamations of the assembly with a diamond ring and a purse full of gold. From this time he was known by the epithet of "the admirable." On the very next day he entered a tilting match at the Louvre, and bore off the ring from all competitors. After serving two years in the civil wars and distinguishing himself alike for

martial and mental prowess, he proceeded to Italy, and was in Rome in 1580. There, according to Dr. Mackenzie, who is but partially supported by Boccalini, he gave another demonstration of his talents and knowledge in a disputation before the pope and all the highest dignitaries of the church and the universities. His challenge was: *Nos Jacobus Crichtonus, Scotus, cuicunque rei propositæ ex improviso respondebimus.* He soon proceeded to Venice, where a Latin poem addressed to Aldus Manutius the younger gained him the friendship of that celebrated printer, and where he was intimately associated with Sperone Speroni, Lorenzo Massa, and Giovanni Donati. He was presented to the doge and senate, and delivered before them an oration which was equally applauded for its brilliant eloquence and consummate grace. He also disputed on questions of divinity, philosophy, and mathematics, with so much ability that Imperiali says "he was esteemed a prodigy of nature." After residing for 4 months in Venice, where he suffered a severe illness, he went in 1581 to Padua, the fame of whose university was then spread throughout Europe. In honor of his arrival the learned men of the place were convened in the house of a person of rank, and Crichton, being presented to them, began his performances by an elegant poem in praise of the city, the university, and the persons present. He then during 6 hours disputed with the doctors on topics of science, especially on the errors of Aristotle and his interpreters, delighting the assembly as much by his modesty as by his wonderful learning and judgment. In conclusion he gave an extemporaneous oration in praise of ignorance, with so much ingenuity, says one of his biographers, that he reconciled his audience to their inferiority. Some one having charged him with being a literary impostor whose attainments were only superficial, he caused a placard to be posted, in which he undertook to refute innumerable fallacies of Aristotle and the schoolmen, and to answer his antagonists, on any topic which they might propose, either in the common logical way, or according to the secret doctrine of numbers and mathematical figures, or in any one of a hundred different spècies of verse. The trial, before an audience containing many competent judges of such pretensions, was held in the church of St. John and St. Paul, where for 3 days the young man maintained his propositions with such spirit and energy before an immense concourse of people that he is said to have obtained praises more magnificent than were ever before heard by men. This, the last of his scholastic contests, was styled by Aldus Manutius, who was a spectator of his triumph, a "miraculous encounter." He proceeded from Venice to Mantua, where, according to Sir Thomas Urquhart, as much a fabler as a historian, he fought a famous gladiator, who had foiled the ablest masters of fence in Europe, who had marked his way to Mantua by blood, and had recently slain the 3 best swordsmen in that city. Crichton, having challenged him, is said to have shown such dexterity in the fight that he seemed but to be in play, and at length to have pierced the heart of his opponent while "his right foot did beat the cadence of the blow." There is other evidence that Crichton was attracted to Mantua, and that the duke of that city made him preceptor of his son, a riotous and passionate youth. For the amusement of his patron, he composed a comedy, in which he himself represented 15 different characters with wonderful effect, and which was esteemed one of the most ingenious satires ever made upon the follies of mankind. This was the last display of his extraordinary talents and endowments, and immediately preceded his tragic death. On a night of the carnival he was assailed in the street by 3 armed persons in masks. Turning upon them with his sword, he at length disarmed the principal aggressor, who proved to be his pupil, the son of the duke. Crichton immediately fell upon his knee, and presented his sword to the prince, who instantly pierced him through the body. In consequence of this event the court of Mantua went into mourning for 9 months, and it was said that the elegies and epitaphs written on his memory and affixed to his hearse exceeded in bulk the works of Homer. Though his splendid reputation and career are linked with romance, and though the 4 Latin odes and the few prose fragments which alone remain of his compositions do not convey an impression of remarkable powers, yet the historical evidence is sufficient to prove that he was a very extraordinary person in respect of capacity and energy, and that he possessed wonderful proficiency in science, literature, and gentlemanly accomplishments.—Sir Thomas Urquhart's "Discovery of a Most Exquisite Jewel" (London, 1652) was written about 70 years after Crichton's death, and abounds in extravagant opinions; his unsupported testimony is therefore not authoritative. Dr. Mackenzie, in his "Lives of Scotch Writers," quotes from Pasquier an account of the exploits at Paris of a wonderful youth, which might have applied to Crichton, but that the year 1445 is given as the date of his appearance. Neither Tytler, Pennant, nor Dr. Johnson (81st "Adventurer") made rigorous examination of the ancient authorities. The chief contemporary evidence is given by Aldus Manutius, who was indisputably a witness of Crichton's intellectual exertions at Venice and Padua, and whose *Paradoxa Ciceronis* has been the foundation of subsequent biographies. An Italian broadside printed at Venice in 1580, discovered by Tytler, confirms the current account of Crichton's accomplishments. Imperiali, in his *Musæum Historicum* (Venice, 1640), gives information derived from his father, who as a youth had seen Crichton at Padua. Scaliger also relates traditions of him as a "very wonderful genius" which he obtained

in Italy. There are several other confirmatory allusions to him in writings belonging to the first half century after his death.

CRICKET, an insect belonging to the order *orthoptera*, the group *saltatoria*, and the family *achetadæ*. Like other insects of the order, the crickets have straight wings, which, when not in use, are folded lengthwise along the back, the upper wings having a narrow border which is folded down so as to cover also the sides of the body; the jaws move transversely like those of beetles; they do not undergo a complete metamorphosis, the young resembling the parents except that they have no wings; in the pupa state they have the rudiments of wings, eat voraciously, and grow rapidly. In the *saltatoria*, which include also grasshoppers and locusts, the thighs of the hind legs are greatly developed, enabling them to take long leaps. In the family to which the cricket belongs, the wing covers are horizontal, the antennæ long and tapering, the feet 3-jointed (except *œcanthus*, which has 4 joints to the hind feet), 2 tapering downy bristles at the end of the body, between which, in the females, there is a long and sharp piercer. The common house cricket of Europe (*acheta domestica*, Linn.) is about an inch long, of a yellowish or clay color mixed with brown; it dwells in the cracks of walls and floors, and in warm places, as the vicinity of ovens, where it remains concealed during the day, coming forth at night in search of bread, meal, and almost any article of domestic economy which contains moisture; it is said also to devour other insects. The female has a long ovipositor, and the male makes a loud noise or chirp by rubbing the hard internal border of one wing cover against a horny ridge on the under surface of the other; for this familiar sound the cricket has been immortalized in the verse of Cowper and the prose of Dickens, and its merry chirp is interwoven in some of the most cheering superstitions of England; its very presence in a house was a sign of good luck, and its flying away a very bad omen. It is a most indefatigable musician, commencing its tune at twilight and keeping it up without intermission till daybreak; its note is so agreeable to some that it is kept in cages by the fireside, as a pet songster, and Scaliger is said always to have had a box of them singing on his table, though this last refers more particularly to the field cricket. This species (*A. campestris*, Fabr.) is larger than the preceding, of a blackish hue, with the base of the wing covers yellowish; in July the female lays about 300 eggs, which are hatched in 15 days; the young have no wings, and feed on vegetable matters, changing their skins before winter; they remain torpid in winter, and become perfect insects in the following June. This species is spread over Europe, where it affords great sport to children, who hunt for it with an ant attached to a hair; from the eagerness with which it comes out of its hole in the earth when any foreign body is presented to it, thus falling into the hands of its enemies, has arisen the expression prevalent in France, "silly as a cricket;" in England the people are more apt to say "merry as a cricket." Their holes are made at first horizontal and then vertical, and they retreat into them backward; they eat grass, seeds, and fruit, carrying them to their holes; they are fond of drinking the dew on leaves and flowers, but are very careful to avoid wetting themselves in their journeys. The young live together in peace under stones and sticks, but when they have attained the full size they are constantly fighting with each other; the field crickets are sometimes made use of in ridding a dwelling of house crickets, the larger instantly declaring war against the smaller species and driving them out. The boys in Germany are very fond of keeping crickets in boxes for the sake of their song, and for the purpose of making them fight; what the game cock is to the Havanese, and the bull-dog to the English, the cricket is to the youth of Germany; according to the direction in which they meet, they will butt like rams, kick like horses, or scratch like cats, never ceasing till one leaves the field or is disabled. There are several species of cricket in America, though there is no house cricket. Our common field species (*A. abbreviata*, Harris) is named from the shortness of its wings, which do not extend beyond the wing covers; it is about ¾ of an inch long, black, with a brownish tinge at the base of the wing covers, and a pale line on each side most distinct in the female. Another species (*A. nigra*, Harris) is entirely black, with very short wings, and measuring ⅜ of an inch in length. Crickets are generally nocturnal and solitary, but some species are often seen in the daytime crawling along our garden paths in great numbers. Our nocturnal crickets do not excite the same pleasant associations as the European species do; they do not enter our houses unless by accident, and their monotonous notes, continued during the autumn nights, are to most persons dismal and sad. Where crickets are numerous, they injure vegetation, eating the tenderest parts of plants, destroying great numbers of melons, squashes, potatoes, &c.; they devour other insects, and thus in a certain degree are of service. They may be destroyed by arsenic mixed in grated vegetables, or in bottles partly filled with fluid, into which they crowd to drink; cats are fond of them, playing with them like mice before eating them; swine also devour them eagerly. There is here a third species (*A. vittata*, Harris, genus *nemobius* of Serville), destitute of wings, varying in color from rusty black to dusky brown, with black lines on the back and posterior thighs; it is about ⅔ of an inch long, social in its habits, frequenting the meadows and roadsides in the daytime. There is another kind inhabiting shrubs, vines, and trees, concealing itself in the daytime among the leaves; these are very noisy, producing their sounds by the rubbing of the wing covers, and if one gets into a chamber it will effectually prevent sleep; the antennæ and legs are very long and slender,

and the piercer is only half as long as the body. They form the genus *œcanthus*, and are called tree or climbing crickets; there are 3 species in the United States, of which the *Œ. niveus* inhabits Massachusetts. The male is of a pale ivory color, with the upper side of the 1st joint of the antennæ and between the eyes ochre yellow, and a minute black dot on the under side of the 1st and 2d joints of the antennæ; the length is about ¼ an inch. They sometimes pierce peach twigs for the purpose of laying their eggs, and they injure the tobacco plant by eating holes in the leaves. They are difficult to catch, from their extreme shyness. The eggs are laid in the beginning of autumn, but are not hatched till the following summer; they attain maturity by the 1st of August, and in southern climates before that time. The females are the largest, and are almost white, dusky beneath, with 3 dusky stripes on the head and thorax, and the wings with a greenish tinge and larger than the covers.

CRICKET, an athletic game much played in England and America, which, according to Strutt, takes its origin from the ancient game of club-ball, which was played with a straight bat, but without wickets. In an illustration of club-ball found in a Bodleian MS. dated 1344, a female is represented in the act of throwing the ball to the batsman, who elevates his bat to strike it, while behind the woman are other figures of both sexes waiting to catch or stop it. By name, cricket cannot be traced further back than to a passage in Phillips's "Mysteries of Love and Eloquence," in 1685. In the beginning of the last century, it is alluded to in an old ballad published by D'Urfey, "Of a Noble Race was Shenken:"

> Hur was the prettiest fellow
> At foot-ball and at cricket.

Of the ancient mode and of the rules for playing cricket but little has come down to us; the game is now governed by a set of laws, arising from the necessities of the play, elaborated by nearly a century's practice, and forming a complete code. Till within the last 80 years cricket was but rarely played in England, though there is plenty of evidence of its existence as a game in the 16th century, and probably even earlier than that. In America its introduction has been quite recent, and it has become generally popular only within the last 4 years. It is now the favorite outdoor game, both of town and country. It lasts from spring till autumn, though chiefly played in the latter, depending a great deal on the weather, as it requires a dry sod, as well as freedom from any present fall of rain. The essentials for playing are: 1, the ball; 2, the bat; 3, the wickets; 4, a field of as short and level turf as can be obtained. It is also well to have a line of 22 feet in length, and a frame of wood 6 feet 8 inches by 4 feet, for measuring the ground and fixing the bowling and popping creases, a tent in case of rain, scoring books, gloves and leg guards to protect the hands and legs in fast bowling, and spiked shoes to prevent slipping.—The game is played either as "single wicket" or as "double wicket." Single wicket requires one wicket, one popping crease, one bowling crease, one ball, one bat; and it may be played by any number of players, arranged in two sides, not exceeding 7 or 8 on each side. The laws of this game differ somewhat from those of double wicket, which is played with one ball, 2 bats, 2 wickets, 2 popping creases, 2 bowling creases, and 2 sides of players, one of which must consist of 11, and the other, though not limited, is usually of the same number. The laws of the game in the United States are the same essentially as those in England, and the code, revised by the Marylebone club, held as the highest authority in this game, is as follows:

Double Wicket.

1. The ball must weigh not less than 5¼ oz. nor more than 5½ oz., nor measure less than 9 inches in circumference nor more than 9¼ inches. At the beginning of each innings either party may call for a new ball.
2. The bat must not exceed in width 4¼ inches, nor in length 38 inches.
3. The stumps must be 3 in number, 27 inches out of the ground; the bails 8 inches in length, the stumps of equal and sufficient thickness to prevent the ball from passing through.
4. The bowling crease must be in a line with the stumps, 6 feet 8 inches in length, the stumps in the centre, with a return crease at each, toward the bowler at right angles.
5. The popping crease must be 4 feet from the wicket, parallel to it, and unlimited in length, but not shorter than the bowling crease.
6. The wickets must be pitched opposite each other by the umpires, at the distance of 22 yards.

Of the remaining rules we give a brief abstract:

7. Neither party without the consent of the other shall alter the ground.
8. After rain, both parties consenting, wickets may be changed.
9. The bowler shall bowl with one foot behind the bowling crease, and after bowling 4 balls shall change wickets.
10. The ball must be bowled, not thrown or jerked; the hand in delivery must not be above the shoulder.
11. Bowler at his wicket may require striker to stand on either side.
12. If bowler tosses the ball over the striker's head, or bowls so wide that it is beyond batsman's reach, one run shall be counted to party having innings by the umpire.
13. If the bowler deliver a "no ball," or a "wide ball," the striker shall be allowed as many runs as he can get, and shall not be put out except by running out.
14. At the beginning of each innings each umpire shall call play.
15. The striker is out if the bails be bowled off, or stump bowled out of the ground;
16. If the ball, from stroke of bat or hand, but not wrist, be caught before it touch the ground, and held;
17. If, in striking, both feet are over the popping crease;
18. If he knock down his own wicket;
19. If he prevent the ball from being caught, the striker of the ball is out;
20. If the ball be struck and he strike it again;
21. If his wicket is knocked off before he can ground his bat over the popping crease;
22. If any part of his dress knock the wicket down:
23. If he touch or take the ball, except at the request of the opposite party;
24. If he stop a ball by any portion of his person, which ball would otherwise have hit the wicket.
25. If the players cross, he that runs for the wicket that is down is out.
26. No runs are counted, the ball being caught.
27. The striker being run out, that run is not counted.
28. "Lost ball" being called, the striker is allowed 6 runs; he shall have all that he has run if there are more than 6 before calling "lost ball."
29. The bowler may put striker out if before delivery the striker is beyond the popping crease.
30. The striker shall not leave his wicket and return to finish his innings after another has been in without the consent of the opposite party.

31. No substitute shall be allowed without the consent of the opposite party.
32. Opposite party must also consent as to what place substitute may have.
33. Opposite party count 5 if any fieldsman stop the ball with his hat.
34. The ball having been hit, the striker may guard his wicket with his bat, or any part of his body, save his hands.
35. The wicket keeper shall not take the ball for the purpose of stumping until it has passed the wicket; he must not move till the ball be out of the bowler's hands.
36. The umpires are sole judges of fair and unfair play.
37. The umpires in all matches shall pitch fair wickets.
38. They shall allow 2 minutes for each striker to come in, and 10 minutes between each innings; when they call "play," the party refusing loses the match.
39. They are not to order a striker out unless appealed to by the adversaries.
40. If one of the bowler's feet is not on the ground behind the bowling crease, and within the return crease, the ball so delivered must be declared by the umpire "no ball."
41. If either of the strikers run a short run, it must be called by umpire "one short."
42. No umpire shall be allowed to bet.
43. No umpire, but with the consent of both parties, may be changed during the match.
44. After the delivery of 4 balls the umpire must call "over," but not until the ball shall be finally settled in the wicket keeper's hand.
45. The umpire must call "no ball" instantly on delivery of wide ball when it passes the striker.
46. The players who go in second shall follow their innings if they have obtained 80 runs less than their antagonists, except in all matches limited to one day's play, when the number shall be 60 instead of 80.
47. No person shall use the bat after one of the strikers has been put out until the next striker shall come in.

Single Wicket.

1. When there shall be less than 5 players on a side, bounds shall be placed 22 yards each in a line from the off and leg stump.
2. The ball must be hit before the bounds to entitle the striker to a run.
3. When the striker shall hit the ball, one of his feet must be on the ground and behind the popping crease, otherwise it is "no hit."
4. When there are less than 5 players on a side, neither byes nor overthrows shall be allowed, nor shall the striker be caught out nor stumped out.
5. The fieldsman must return the ball so that it shall cross the play between the wicket and the bowling stump, or between the bowling stump and the bounds.
6. If the striker has made one run, if he start again he must touch the bowling stump.
7. The striker is entitled to 3 runs for "lost ball" (referring to law 28 of double wicket).
8. When there are more than 4 players on a side there shall be no bounds; all hits, byes, and overthrows shall then be allowed.
9. The bowler is subject to the laws of double wicket.
10. Not more than one minute shall be allowed between each ball.

In single wicket the stumps are driven into the ground, subject to the laws 3 and 5 of double wicket; in front a popping crease is marked off, as in law 5; at 22 yards' distance a bowling stump is fixed; a bowling crease must be marked at the proper distance, as in law 4, and here the bowler must deliver his ball, as defined by laws 9, 10, 12, 13, and 14. The game is defended by the batsman, or striker, who stands at the popping crease. The attack is conducted by the other side, placed in the field according to their numbers.—Double wicket usually consists of 2 sides of 11 players each; one of these has the innings by lot, and 2 of their party defend the wicket with their bats. By the other side, who are now fielding, the attack is maintained; if the bail is knocked off, or the stump is bowled out of the ground, the striker is out, and is replaced by another till all the side are put out. If, on the other hand, the ball is struck, each run counts one, and the side which makes the greatest score is the winner. Two captains are chosen, one for each side, generally the 2 best bowlers, and they choose their assistants, and allot each their respective places when fielding. When matches are made between 2 clubs, the men are selected by a committee from each club. One bowler at a time is indispensable, who bowls 4 balls, called an "over;" then the whole of the fielders walk over to the opposite side, and another over of 4 balls is delivered from the opposite wicket by another bowler. For fast bowling the men are stationed as follows: Immediately behind the wicket is the wicket keeper, whose duty it is to stop the ball, an office of no little labor and risk, for which tubular gloves and leg and body guards are absolutely required. Behind the wicket keeper are the long stop and assistant; the short slip is in a line with, and on the right of, the wicket keeper; the long slip is in the same line further to the right; the leg is behind and to the left of the wicket keeper; behind the bowler and on his left is the long field off, to the bowler's right the long field on; to the right of the striker are the mid wicket, cover point, and point. The duty of these is merely to stop the ball, and they take their names from the places assigned. There are 2 kinds of bowling, fast and slow; the fast is almost always "round-handed;" the straight underhand balls are much more easy to guard; where, however, the ball twists, the matter is much more difficult. In round-handed bowling the ball has a turn on its own axis, independent of its forward motion, and when it appears as if running clear of the wicket, it yet will twist and take the outside stump. Where the bowling is slow, and there is but little hard hitting, the fielders are brought nearer in, to get, if possible, near catches, from the tendency of good slow balls to rise if only tipped. The terms descriptive of the varieties of balls are "lengths" and "not lengths," the latter consisting of toss, tice, long hop, half volley, and ground ball. In bowling, the ball should be delivered with a run, and should be held with the seam across, so that the ends of the fingers touch it.—The dress of a cricketer is almost always a light flannel jacket, with trousers of the same, or of white duck; a straw hat or light cap is generally adopted; leg guards and body guards are used in batting and wicket keeping; and gloves, Oxford shoes, or shoes with spiked soles, complete the arrangement.

CRILLON, a French family derived from the Piedmontese Balbes who emigrated to France in the 15th century. I. Louis des Balbes de Berton de Crillon, the hero of the reigns of Henry II., Francis II., Charles IX., Henry III., and Henry IV., born at Murs in Provence in 1541, died in 1615. He was the first to assume the name of Crillon, from a small estate of that name situated in the present department of Vaucluse. Having become glorious by his exploits, the name was adopted by the whole family. As the youngest of 6 brothers, he was destined for the order of the knights of Malta, studied with zeal and dili-

gence at the school of Avignon, and eagerly pursued bodily and chivalric exercises. Under Francis de Lorraine, duke of Guise, he completed his education as a warrior and cavalier in his 16th year. Under the command of the duke he was the first on the walls of Calais, which had been for 2 centuries in the hands of the English, and was now taken after a siege of 8 days (1558). He equally distinguished himself at the capture of Guines. Adored for his extraordinary bravery by the army, he was presented by his commander, the duke of Guise, to Henry II., as the chief instrument of his victories, and richly rewarded by numerous clerical estates, it being at that period customary in France to bestow benefices on laymen, to be managed for their benefit by members of the clergy. In the ensuing civil wars of France he served against the Huguenots, defeating the conspiracy of Amboise, formed against the Guises (1560), and fighting in the battles of Rouen, Dreux, St. Denis, Jarnac, Moncontour, and St. Jean d'Angély. As a knight of Malta he fought under Don John of Austria at Lepanto, against the Turks (1571), was wounded, and sent with the news of the victory to Charles IX. of France, and Pope Pius V. Already called "the brave" by the court of France, and "the man without fear" by the army, he became the object of general admiration. He now had his first duel with Bussy d'Amboise, who, meeting him in the street, asked him haughtily: "What is the hour?" and was answered: "The hour of your death!" He afterward saved the life of Bussy, and won his friendship. He took no part in the massacre of St. Bartholomew's (1572), which he freely condemned, though he continued to serve against the Huguenots. The duke of Anjou, brother of the king, having been elected king of Poland (1573) after the extinction of the house of Jagiello, he followed him to that country through Germany, where he defended his dignity against the insults of the irritated Protestants, and on his flight thence, when he succeeded as Henry III. to the throne of France. On his return he was distinguished with new honors by the cities of Venice and Lyons. When, after the battle of Coutras (1587), Henry III. openly commenced hostilities against the league, and the states assembled at Blois decreed the assassination of the duke of Guise, who had followed his father in the leadership of the Catholics, the monarch offered Crillon the honor of killing the duke, which he refused. He afterward fought for the king against the league, and, after the assassination of Henry III., served with equal fidelity the new king, Henry IV. The battle of Ivry (1590) ended his services in the civil wars. Henry IV., who called him "the brave of the brave," said: "I have never feared any but Crillon;" and wrote to him after the battle of Arques: "Hang yourself, Crillon; we have conquered without you." In the war against Spain, Crillon was active again. The peace of Savoy ended his military career, when he retired to Avignon.

The chivalric bravery of Crillon was equalled by his generosity, which prompted him even to pardon an attempt at his own assassination. The estates of the family were inherited by Thomas, the 3d of the brothers, and made in the 4th generation a duchy by Benedict XIII. II. The 2d duke of Crillon was Louis, born in 1718, died in 1796 at Madrid. Having entered the French army at the age of 13, he fought under Villars in the campaign of 1733 in Italy, and distinguished himself in Germany. Entering the Spanish service in 1762, he conquered Minorca (1782), and was rewarded by the title of duke of Mahon, and became captain-general of the provinces of Valencia and Murcia. His *Mémoires* (Paris, 1791) contain many particulars valued by men of military science. III. Louis Antoine François de Paule de Crillon, duke of Mahon and grandee of Spain, son of the preceding, born in 1775, died in 1832. Made a colonel in the Spanish army at the age of 15, he was captured with his regiment on the invasion of France in 1794. After the peace he served, with the permission of his government, as volunteer under Moreau; then again in Spain, where he became commander of a division, governor of Tortosa, and in 1807 captain-general of Guipuzcoa, Alava, and Biscay, in which capacity he faithfully guarded the northern fortresses against the generals of Napoleon, until he was expressly commanded by the king, who rejected his warnings, to surrender them to the French. After the fall of the Bourbons he swore allegiance to Joseph, brother of Napoleon, and was made lieutenant-general of the Spanish army, and successively captain-general of Navarre, Toledo, and Cuenca. Proscribed by the returning Bourbons in 1814, he fled to France, where he remained, and received the title of lieutenant-general. Of the 2 sons of his brother, Félix Dorothée, who was peer of France, and died in 1820, one served under the restoration, in the army, and as peer of France, the other under Napoleon and the restoration.

CRIMEA, a peninsula forming the southern extremity of the Russian empire in Europe. It extends between lat. 44° and 46° N. and long. 32° and 37° E.; greatest extent from E. to W. 190 m., from N. to S. 123 m.; area about 8,000 sq. m. This peninsula is connected with the main body of the empire by the narrow isthmus of Perekop, the breadth of which is less than 5 m. Though only the 260th part of European Russia, the Crimea, in consequence of its geographical, commercial, and strategetical position, is one of the most important divisions of the empire, commanding as it does the navigation of the Black sea. It has a coast line of 550 m. Along its N. E. shore there extends a long and narrow inlet of the sea of Azof, from which it is separated by a tongue of land, or rather a sand bar, about 70 m. in length and 1 to 1½ m. in breadth. This inlet is so shallow that in some places it has the appearance of a morass, and its very name (Sivash, or Putrid sea) indicates its general aspect. The eastern part of the

Crimea forms a minor peninsula, stretching eastward to the strait of Yenikale, the Cimmerian Bosporus of the ancients. While the N. portion of the peninsula is only a continuation of the steppes of S. Russia, barren, cheerless, and swept by chilling winds, the S. portion, sloping from a mountain chain which stretches from Sebastopol to Kaffa as a barrier, enjoys a semi-tropical climate and a great richness and variety of vegetation. Hence the N. portion has from time immemorial been occupied by nomadic tribes, eking out a scanty subsistence by cattle-raising; while on the S. slope higher forms of culture have been developed by the Greeks, the Genoese, the Tartars, and the Russians, successively. There is only a comparatively narrow belt of arable soil on the northern slope, and on this belt the most important towns are situated, such as Sebastopol, Bakhtchissarai (the old capital of the Tartar rulers), Simferopol, Staroi Krym, and Karasoo-Bazar. To the northward of this belt extends the steppe, its monotony relieved only by numerous herds of cattle and thousands of cranes, storks, and gulls, swarming around the salt-water lagoons and marshes. The mountain chain (Jaila), mentioned before, appears to be a western continuation of the Caucasus, from which it is separated only by the strait of Yenikale. In the Tchatir-dagh, or Tent mountain (the Trapezus or Table mountain of the ancients), it attains to an elevation of 5,051 feet above the level of the sea, and terminates to the southward of Sebastopol in the promontory called Crion Metopon (Ram's Face) by the Greeks, and Ai Burun (Holy Cape) by the Tartars. The S. coast, to which the principal chain sends several small branches, is exceedingly picturesque in appearance. Wherever the slope of the hillsides is not too steep, they are covered with vineyards and the country houses of the rich; the valleys, watered by numerous small streams, are carefully cultivated and produce rich crops of grain and fruit; the mountains abound in valuable timber. The N. steppe, on the other hand, is almost entirely destitute of fresh-water springs and rivers, and its soil is generally impregnated with salt.—The 2 principal rivers of the Crimea are the Salghir, which rises from a cavern near Simferopol, at the northern foot of the Tchatir-dagh, and empties into the Putrid sea, and its tributary, the Karasoo (Black Water), which rises from the same mountain a little further E. Of the smaller streams, the Alma, running a little N. of Sebastopol from E. to W., has become widely known by the battle fought on its banks, Sept. 20, 1854.—The climate of the Crimea is salubrious and delightful in the springtime, but irregular and generally very hot in summer, a temperature of 100° F. being quite common. The autumn is considered unhealthy, fever and ague prevailing at that time of the year in the lowlands. In winter the weather is often extremely severe, more so than in most other parts of Europe in the same latitude. The apples raised in the southern Crimea are excellent, and command high prices in the market of Moscow. All the various kinds of grain, including maize, also peas, hemp, and tobacco, are grown in the fields; olives, melons, watermelons, gourds, cucumbers, in gardens; quinces, plums, peaches, apricots, cherries, mulberries, walnuts, hazlenuts, chestnuts, are among the vegetable products of the Crimea. Of wild animals, only deer, wolves, badgers, foxes, hares, weasels, and jerboas are found; camels are employed on the northern steppes, where also buffaloes and oxen, sheep and goats, are raised. The horses of the Crimea are more remarkable for activity and intelligence than beauty. The birds most common are crows, owls, thrushes, blackbirds, partridges, quails, kingfishers, pigeons, and poultry, geese, swans, ducks, teals, gulls. Among the insects, the hideous *rana variabilis*, scorpions, tarantula spiders, and scolopendras may be mentioned. Bees are abundant; so are fish on the coast, but not in the rivers. The production of grain increased from 350,000 quarters in 1841 to 850,000 in 1851. Agriculture is most developed in the district of Berdiansk, peopled by foreign settlers. The Crimea possessed in 1851 about 2,000,000 sheep, half of which were fine-wooled, 85,700 horses, and 248,260 horned cattle. The salt manufacture is monopolized by government; the most celebrated salt mines are those of Perekop and Eupatoria. The number of vines increased from 5,929,500 in 1832 to 35,577,000 in 1848; and the entire vintage of the Crimea amounted in 1851 to about 3,500,000 gallons. The Crimean wines which are exported are generally of a secondary quality, and are chiefly used for mixing with other wines. The vineyards of Prince Woronzoff are highly esteemed, and yield a sparkling wine, something like champagne. The principal articles of export are salt, wine, honey, wax, leather, hides, wool, lamb skins, and morocco leather; and an active transit trade exists, corn, seeds, tallow, tobacco, and silk being brought here for barter with European, and especially Russian manufacturers.—The population of the peninsula is a mixture of the Greek, Italian, Tartar, and Slavonian nationalities. There are, beside, Armenians, Caraite Jews, Greeks, gypsies, and also 9 German colonies established in 1804–'5, and reënforced in 1816–'17 by 1,400 Swabian families, but numbering at present only about 1,800. The Tartars (Mohammedans), in former times so numerous that they were able to muster 100,000 warriors, still constitute the principal part of the population, the entire number of which is given at 200,000.—The Crimea, with a part of the province of Taurida, was acquired by Russia toward the end of the 18th century. Its aboriginal inhabitants, the Cimmerians, having been driven out by other Scythians, left only a small remnant (the Tauri) in the mountain recesses, and from them the ancient name of the country, Tauris or Chersonesus Taurica, was derived. It was celebrated by the legends of Iphigenia and Orestes; was the chief possession of the Greek kingdom of the Bosporus; was held under Roman protection,

and subsequently conquered by the barbarian tribes which invaded the eastern provinces of the Roman empire. Early in the middle ages it belonged to the Byzantine empire. Toward the end of the 12th century the Genoese and Venetians obtained a foothold. Kaffa and Cherson were established by the former, Tana by the latter. The Tartars overran the peninsula in the 13th century, and maintained their rule for more than 200 years, when they became subject to the Ottomans. Still all their municipal institutions were left undisturbed by the conquerors, who even allowed the Tartars to retain their own khans (princes), though as vassals of the sultan. In the latter portion of the 17th century the Russians began to covet the Crimea, and in 1771 they succeeded so far as to wrest it from Turkey and clothe it with a nominal national independence. In 1783 the khan Shahin Gherai, having been expelled from the Crimea by the anti-Russian party, ceded his country to Russia, and in 1784 the peninsula and its adjoining provinces were annexed to the empire. The peninsula is divided into 4 districts: Simferopol, Feodosia, Yalta, and Eupatoria. The capital, Simferopol, has only 8,600 inhabitants, and has lost all vestiges of its former splendor as the residence of the Tartar khans. It had been outgrown by Sebastopol before the destruction of that place in 1855, and by Eupatoria (Kozlov), Bakhtchisarai, Feodosia, and Kertch. The latter, the old *Panticapæum*, is almost the only town in Russia that is built entirely of stone; its population amounts to about 10,000 souls. Karasoobazar, situate to the N. E. of Simferopol and containing about 15,000 inhabitants, is the principal seat of what little industry the Crimea can boast of.—The Crimea was, in 1854 and 1855, the principal theatre of the war between the allied western powers and Russia. The armies of the allies effected a landing at the bay of Eupatoria, Sept. 14, 1854. On their southward march toward Sebastopol they encountered the Russian forces, commanded by Prince Mentchikoff, on the banks of the Alma. A bloody battle was fought (Sept. 20), in which the Russians were compelled to retreat. On Sept. 25 the British forces seized Balaklava, and on Oct. 9 the regular siege of the southern portion of Sebastopol commenced, the Russians having sunk vessels in the entrance to the harbor and thus rendered the city unassailable by maritime force. On Oct. 25 and Nov. 5, the Russians vainly attempted to annihilate the besieging forces in the battles of Balaklava and Inkerman, but afterward confined themselves mainly to the defensive, their frequent sorties being intended more to harass and retard the siege than to relieve the place definitively. Among these conflicts some assumed almost the character of regular field battles; for instance, an unsuccessful attack of the French upon a new redoubt (Feb. 23, 1855), their first assault upon the Malakoff and Redan (June 18), and the battle of the Tchernaya (Aug. 16), in which the Russians, numbering 50,000 infantry and 6,000 cavalry, made a last effort to break the aggressive force of the enemy. The trenches having been driven so near the Russian defensive works that another assault could be ventured, the final bombardment was opened Sept. 5, and lasted for 3 days. On Sept. 8 the Malakoff and Redan were stormed and taken by the allies after a desperate struggle. The Russians, after having blown up their extensive fortifications on the southern shore of the harbor, retreated to the north side, which the allies never seriously attempted to conquer. The latter, having destroyed the costly docks, arsenals, and ship yards of Sebastopol, remained inactive in their camp, and, with the exception of the capture and sack of Kertch on the strait of Yenikale, no further feats of arms were accomplished. The forces of the allies were withdrawn in the summer and autumn of 1856. In the latter part of 1858, two brothers of the emperor made a tour of inspection in the Crimea, and it was rumored that it was the intention of the government to establish a city like Sebastopol at or near the strait of Yenikale.—On April 10, 1856, Col. Munro exhibited in the London society of antiquaries a great number of relics discovered beneath a spot between Balaklava and Sebastopol which had been used throughout the war as the provision depot of the English camp. The first intimation of the antiquities was the turning up of a coin of Romanus, and at length an oblong enclosure was cleared out measuring 150 feet by 93, having at one end a circular form and walls 10 feet in thickness, comprising a Cyclopean wall and an inner wall of wrought masonry. These remains are supposed to be those of a temple, dating from 400 to 200 B. C. Beside a beautiful small female head in terra cotta, presumed to be Astarte or some other divinity, which has been presented to the queen of England, 16 vases and fragments of pottery, glass beads, fibulæ, spear heads, and other antiquities, were discovered on the same occasion in the Crimea. On Dec. 5, 1856, Dr. Duncan McPherson, who had officiated as inspector-general of hospitals of the Turkish contingent, gave before the same society a description of the excavations conducted under his care, on the site of Pantecapæum and the Mons Mithridates, in the immediate vicinity of Kertch; and has since published a splendid illustrated work in folio, with drawings of tombs and other relics, including some curiously constructed chambers. Many of these antiquities have since been deposited in the British museum.

CRIMINAL LAW. This branch of jurisprudence is the earliest in development, but the latest to be reduced to a rational and consistent system. The predominance of penal laws may be seen in the early legislation of every nation. The reason is, that in a rude state of society personal violence is the most pressing subject for which laws are required. Laws are accordingly enacted for the emergency, and, as might be expected, having reference to the immediate occasion, they partake rather of blind popu-

lar impulse than the calm deliberation of legislative wisdom; not that the laws are in fact dictated by the will of the people, but the legislators themselves are under the influence of the same prejudices that actuate the popular mind. The consequence is, that excessive severity at first prevails, which in the course of time is meliorated by evasion of the laws, and the contrary extreme of undue laxity has in many instances succeeded. The latter effect can be guarded against only by a timely revision of the laws, and an accommodation of them to the more humane views resulting from an advance of civilization. But, as we shall have occasion to show more particularly in the course of this article, the practical wisdom required for such a revision is the very latest growth of civilization, and belongs to the highest branch of political science. It has indeed been erroneously supposed that criminal law is extremely simple as compared with the laws relating to property. This idea has grown out of the fact that legislation respecting crimes has by necessity been called for when as yet the state of society was unsettled. Laws were made for individual cases, and by consequence were destitute of sound legal discrimination; yet by long use, and for want of the capacity required for systematic review and amendment, they have become fixed in all their incongruity. This irregular character of criminal laws is not peculiar to one or a few nations, but is observable in all systems of jurisprudence which have not in a later and more mature age undergone revision. Hence criminal law has more a statutory or positive character than the more gradually developed system of laws affecting property. In the absence of general principles and of all harmonizing method, each statute or provision of law is isolated, distinct, and positive, and therefore precludes all reasoning by analogy and all modification for the sake of conformity to the changing circumstances of society. So far, then, criminal law may be said to be simple, inasmuch as each statute is the law of the particular case referred to, and there can be no expansion or reproduction by analogy. Yet there are principles applicable to this branch of the law, which may, in like manner as the elementary rules of civil law, be developed into a harmonious system. Another peculiarity of criminal law, or rather of its administration at an early period, is the want of discrimination as to the palliative circumstances of crime. Motives are comparatively little considered in early penal laws, or in the judicial proceedings founded upon them. Gibbon's remark, that "the life or death of a citizen is determined with less caution and delay than the most ordinary question of covenant or inheritance," is true only of a jurisprudence which has retained its early crude legislation respecting crimes without subsequent revision. To a considerable extent this was the state of the English criminal law at the time Gibbon wrote, but it has since that time undergone a radical change. There is a third characteristic of the early administration of criminal law, viz.: the comparative disregard of the rules of evidence. The fact of being charged with a crime, especially if there be some strong circumstance of suspicion, naturally induces a prejudice against the accused. He is deemed guilty until he proves himself innocent; contrary to the more humane axiom of a later age, that a man is to be deemed innocent until he is proved to be guilty. The very atrocity of the crime of which a man is accused is an aggravation of popular prejudice, and in a semi-civilized community is almost equivalent to condemnation. The patient investigation of a case, the careful weighing of all the evidence, particularly that which is derived from circumstances, and the impartial judgment unswayed by popular excitement or the exacerbated passion of the injured party, belong to a more advanced stage of civilization and jurisprudence. Illustrations of the foregoing remarks will be found in the penal laws of nations the most celebrated for their legislation. The laws of Draco, which on account of their undiscriminating severity were said to have been written in blood, are not to be deemed the mere expression of the cruel heart of the legislator, but rather the reflection of the sanguinary disposition of the Athenian people at that period. So the decemvirs who prepared (perhaps merely compiled) the 12 tables did not declare crimes nor impose penalties abhorrent to the popular disposition, but rather were actuated by the same impulses and prejudices which prevailed in the minds of the people. It was not indeed a democratic influence, for some provisions were made expressly for the support of patrician power over the plebeian commonalty; but, allowing a certain degree of discrimination in the estimation of crimes as affecting one or the other class politically, the code of the decemvirs may be assumed to be a fair expression of the temper of the Roman people. Upon analysis of these celebrated laws, all the defects which we have specified as incident to early legislation become apparent. The penal largely predominates over the civil, and in respect to crimes and their penalties there is an absence of what we should deem a just discrimination respecting the relative measure of crimes and the punishment due to each, and there is a want of due regard to motives or other palliative incidents. Mutilation of the person was punished by the retaliatory infliction of the same injury upon the wrong doer. A false witness was to be thrown headlong from the capitol. The killing of a man, or making use of magical words to hurt him, or the preparing of poison for him, or giving it to him, were subject alike to the penalty of death. A parricide was adjudged to be sewn up in a sack and thrown into the river; the addition to the contents of the sack of a cock, a viper, a dog, and an ape, were the fanciful devices of those who executed the law, and not prescribed by the law itself, though in the Institutes of Justinian they appear as if the whole

had been originally so enacted. Slander by words or defamatory verses was punished by beating with a club, and the authorities cited by Gibbon seem to prove that the punishment extended to death. This was undoubtedly a political law, intended in the first instance for the protection of the decemvirs themselves against any rude complaint by the people. It remained, however, unrepealed, though, like other enactments, probably unexecuted, except for tyrannical purposes. The treading down of another's corn field at night was punished with death; but the cutting down of trees, whatever might be the value, was subject to a mere fine of 25 pounds of brass. But the most apt illustration of the irrational severity of these laws was the treatment of an insolvent debtor, who, without any other imputation of fraud than the fact of owing the debt and not having paid it, could be taken home by the creditor and kept 60 days, fettered with irons not exceeding 15 pounds in weight; at the end of which time, if the debt remained unpaid, he could be brought before the people on 3 market days, on the last of which his body could be cut into pieces according to the number of creditors, or, if they preferred, he could be sold into foreign slavery. The excessive severity of a law defeats the very object had in view in enacting it. "The criminal code of the decemvirs," says Gibbon, "was abolished by the humanity of accusers, witnesses, and judges; and impunity became the consequence of immoderate rigor." Magistrates were prohibited from inflicting on a free citizen any capital or even corporal punishment. All cases affecting the life or liberty of a Roman citizen were, by the laws of the 12 tables, to be tried by the *comitia centuriata*. The multiplication of these cases led to the giving power annually to the prætors to sit in judgment on state offences, with a certain number of judges drawn from the rolls of citizens; and new prætors were appointed with special powers for the trial of offences relating only to individuals. There was a general amelioration of the laws by the operation of these different provisions. As there was no arrest until sentence had been pronounced, the judgment could be evaded by going into voluntary exile, and the interdiction of fire and water (*i. e.* exile) became the extreme limit of judicial severity even upon conviction in capital cases. A new administration of criminal law was, however, introduced with the imperial government. The senate was made the instrument of imperial power, for the condemnation of criminals charged with offences against the state; and the ordinary magistrates became invested with powers which under the republic had been reserved to the people, either in the *comitia* or in the popular body of *judices*, who sat with the prætor. Any Roman citizen might be a public accuser and prosecute criminal actions, but it seems not to have been usual, except when some political object was sought, or where the accuser had some relationship to the injured party, either by blood or professionally, as in the case of patron and client. It was a peculiarity of the Roman criminal law that, however mild it became in respect to free citizens, it was enforced against slaves and foreigners with all the stringency of its ancient severity.—The laws of the Germanic nations equally illustrate the propositions above stated, and especially the absence of all classification of crimes, and the disproportion of penalties to the different degrees of moral turpitude. The Salic law contained 343 penal articles, and only 65 on all other subjects. Of the penal laws, 150 related to cases of robbery, 74 of which referred to the stealing of animals; cases of violence against the person were the subjects of 113 articles, of which 30 related to mutilation of the person, and 24 to violence against women. The want of generalization is noticed by Guizot, as proving defect of intellectual development and the precipitation of the legislator in enacting laws: "Every case of robbery, of violence in the very fact, is taken hold of in order to immediately inflict a penalty; and there was no idea but of adding a new article of law whenever a new crime was committed, however trifling its difference from those which had been already provided for." Yet these laws present the same contrast that we have seen in the Roman, in the mildness of the penalties inflicted upon free men, and the cruelty of the punishments to which the slaves, and even bond laborers (*coloni*), were subject. Composition (*wehrgeld* or *widrigeld*), a pecuniary mulct, was the penalty enforced upon a free man, varying in amount with the atrocity of the offence; but upon slaves and laborers, tortures and death were freely inflicted. Similar provisions were contained in the laws of the Ripuarian Franks, the Burgundians, and the Anglo-Saxons. It was, however, understood that the injured party had a right to refuse composition, and to seek satisfaction by his own hand; which last alternative was regulated by certain rules, and hence received the designation of judicial combat. This was a peculiar feature of the Germanic law, and was not confined to criminal cases, but became a common mode of deciding questions of fact even in civil suits; and the right was reciprocal, that is to say, either party had the right to call the other to a decision of the controversy by combat. So either party had the right to challenge witnesses, and even judges, to combat, upon the allegation that the testimony was untrue or the judgment unjust. Montesquieu maintains that the judicial combat was introduced as a natural consequence of what he calls negative proof, that is, the denial of the charge by the party under oath, which was a purgation in criminal cases, and was also admitted in civil cases with the addition of the oaths of a certain number of others, called *conjuratores* or *compurgatores*, who merely deposed that they believed the party. The defect of this kind of proof, as well as of the other mode of determining facts, viz., by ordeal, rendered the trial by combat a necessity;

at least it was far more satisfactory to the rude minds of that period than either of the others, in which perjury and deception were palpable. Another mode, which was much in vogue among the Anglo-Saxons, and which was maintained for a long period in the English law, was the compurgation before alluded to. Whether the compurgators were the same as the *sectatores* spoken of in the Saxon laws is uncertain. It has been supposed by some writers that they had a function somewhat similar to that of the *juratores* of a subsequent period. In one respect they were alike, inasmuch as they stated upon oath their opinion of the case, which opinion was not founded upon evidence, but upon some private knowledge which they were supposed to have of the matter in controversy. There was probably a distinction, however obscure; the one (the juratores) became the modern jury, the other (the compurgators) continued to be called rather as witnesses, though they testified only to belief in what the party had sworn. The proceeding by compurgators was called wager of law, which took the name from the formality of giving gage or security that the party would at a certain day make his law, that is, that he would take an oath and bring 11 compurgators to swear that they believed him. In modern practice it seems to have been admitted only in an action of debt, instances of which may be seen in 2 Salk. 682, and 2 Barn. and Cress. 538; but at the period of which we speak it was a method of proceeding in criminal as well as civil cases. The juratores appear to have been in the first instance charged with the preliminary inquiry as to the guilt of any person charged with certain crimes, and upon their finding him guilty he was put to the ordeal or compurgation. This seems to have been the practice in the reign of Henry II. But we learn from Bracton, who wrote in the reign of Henry III., that the practice then was to commit the decision of the case finally to the jury, unless there was a demand of combat by one of the parties, or unless the defendant elected to wage his law. There was still, however, nothing like the modern proceeding upon a jury trial. The jurors were not expected to decide upon evidence produced by the parties, but upon their own knowledge or information collected by them. The direction of the judge was, that whereas such a man is charged with such a crime, the jury are to make known the truth thereof. Prosecutions for crime were usually upon appeal of a private party. Any one of legal capacity to sue could prosecute for treason, but ordinarily only near kindred by blood were admitted to bring suit for homicide; a woman could prosecute only for the death of her husband, or for a rape committed upon herself, and the appeal in the former case is said by Bracton to have been only *de morte viri inter brachia interfecti*. In other cases the party injured was in general the prosecutor. There was, however, as before mentioned, another mode of charging a person with crime, viz., *per famam patriæ*, a sort of indictment by the *patria* or jury. It does not appear how the prosecution was conducted in such a case; but as there was never any attempt to determine facts according to rules of evidence, it is probable that the first finding or indictment was conclusive, unless the party accused purged himself or took some exception to the jury.—It would exceed our limit to pursue the history of the English criminal law through all its changes. Passing to its present state, we find forms of proceeding eminently adapted to sound judicial investigation. The function of the *patria*, or jury of inquisition, spoken of by Bracton, is now performed by a grand jury, not less than 12 nor more than 23 in number, upon whose indictment most criminal cases are brought before the courts for trial. The exceptions are: 1, cases of homicide where a coroner's inquisition has been returned; 2, actions which, by statute, may be brought by a private prosecutor, or informations by the master of the crown office upon the relation of a private individual; 3, informations filed *ex officio* by the attorney-general in cases of atrocious misdemeanor endangering the government. All criminal prosecutions, except the few cases where by statute a common informer is authorized to bring an action, are in the name of the king, and conducted by his law officers. Private suits for crimes, which were formerly allowed under the name of appeals of felony, were long since practically abandoned, and were finally abolished by statute 59 George III., c. 46. So also the wager of battle by the same statute, and wager of law by 2 and 4 William IV., c. 42. The indictment, which is the basis of the arraignment and trial of criminals, was formerly required to be drawn with great technical strictness, and was often quashed for defect of form. Thus it was necessary to set forth the full name of the person charged and a designation of his business and place of residence, also the time and place when and where the offence was committed. Certain technical words were also required, as descriptive of the crime charged, as (when pleadings were in Latin) the words *proditorie et contra ligientiæ suæ debitum*, in treason; *murdravit*, in an indictment for murder; *rapuit*, in rape; and so in other cases. No expressions equivalent in meaning could be substituted; and after the pleadings were, by statute 4 George II., c. 26 (1730), converted into English, the corresponding vernacular terms, as "murdered," "ravished," &c., were retained with the same strictness. And so in felonies it was necessary to charge that the act was done *felonice;* in burglary, *burglariter*. In indictments for murder it was required also to state the dimensions of the wound, and in all indictments the value of the thing which was the subject of the offence, as in larceny, or with which the offence was committed, as in murder. In the former case, it was said to be required in order to distinguish whether it was grand or petty larceny; in the latter case, because the

instrument with which a homicide was committed was forfeited as a deodand. This absurd regard to mere form has been, however, abrogated: 1st, by statute 7 George IV., c. 64, which prohibited an arrest of judgment or a reversal on writ of error for any of these formal defects, but which still left the objections to be taken advantage of by demurrer; and finally, by 14 and 15 Victoria, c. 100 (1851), commonly called Lord Campbell's act, by which the court is directed to disregard the omission of mere formal words, as "with force and arms," or "against the peace," &c., or any mistake in time or place; and a statement of the manner or means by which the deceased came to his death is dispensed with, and amendments of indictments either in matters of form or substance are allowed upon such terms as the court shall deem reasonable. As to the designation of crimes and their punishments, the English law was, until a recent period, in a chaotic state. Statutes had been accumulated according to the exigencies occurring at different times, until, by their number, such was the difficulty of determining what was obsolete and what in force, and of reconciling apparently conflicting provisions, that practically the common people had no knowledge of the penal laws to which they were subject, and cases were constantly occurring of the trial and conviction of criminals charged with offences, the nature of which, as defined by law, and the penalties prescribed therefor, they were entirely ignorant of; their ignorance, according to the old maxim, *ignorantia juris non excusat*, being no defence. So also the extreme and disproportioned severity of ancient laws enacted in a turbulent period, or in an unsettled state of society, still prevailed in England at the beginning of the present century. According to Blackstone, there were 160 offences which by various acts of parliament had been declared felonies without benefit of clergy, that is to say, punishable by death. It will be sufficient to mention the cases of grand larceny, or stealing above the value of 12 pence; embezzlement of a master's goods by a servant; burning stacks of corn, hay, &c., in the night time; killing horses, sheep, and other domestic animals; breaking down dikes or bridges, or breaking away the banks of fish ponds; cutting down trees in an avenue, or growing in an orchard; the malicious tearing or defacing of the garments of a person passing in the street; all of which, and various other acts of no greater degree of criminality, were thus punished. The origin of this severity in the majority of such cases was no doubt owing to the great prevalence of a particular grievance in some locality, and, according to the former mode of reasoning, the frequency of an evil called for increased severity of punishment; but it has happened that when the emergency has ceased the law remained. Common humanity was outraged by the continuance of such a system of criminal law in a civilized community; public attention was at last directed to the necessity of reform, and a revision has been made by several different statutes, chiefly the following: 7 and 8 Geo. IV., c. 27 (1827), for repealing various statutes relating to benefit of clergy and for other purposes; 7 and 8 Geo. IV., c. 29, for consolidating and amending laws relating to larceny; 7 and 8 Geo. IV., c. 30, for consolidating and amending laws relating to malicious injuries to property; 9 Geo. IV., c. 31 (1828), 1 Victoria, c. 85 (1837), which is a revision of the last preceding act, in respect to attempted homicide; 1 Victoria, c. 86, in respect to burglary and stealing in a house; 1 Victoria, c. 87, respecting robbery and attempting to rob; and 1 Victoria, c. 89, as to burning dwelling houses and other buildings, destroying vessels, exhibiting false signals, &c. From examination of these statutes, it is apparent that it was difficult to make a thorough change at once, and many successive efforts against ancient prejudices were required. Thus by one of the acts of 1827 the distinction between grand and petty larceny was abrogated, and every theft which had come under either denomination was declared to be simple larceny, punishable only by transportation or imprisonment, with the addition of whipping, in the discretion of the court. Yet by the same statute stealing from the person was punishable by death; so also the breaking into a dwelling house with intent to commit a felony, or breaking in and stealing from a dwelling house a chattel of any value, or stealing from a dwelling house and at the same time putting any one in fear, or stealing to the value of £5, stealing a horse, cow, &c., or killing with intent to steal the carcass or skin, were all punished by death; so also, by the act of 1828, an attempt to murder by administering poison, or by suffocating, or strangling, or by shooting with loaded weapons, or stabbing, &c. In the amendatory acts of 1837, transportation or imprisonment was substituted in most of the cases in which capital punishment had been retained by the previous acts. By the existing laws of England, the cases in which the penalty of death is inflicted are the following: treason; murder; burglary with intent to kill, or accompanied with violence to any person; robbery, if at the same time any injury be done by a weapon; burning a dwelling house, there being a person therein at the time; crimes against nature, called buggery and sodomy; casting away a vessel, whereby the life of any person is endangered; exhibiting false signals, with the intent to bring vessels into danger. In all other cases, the penalty is penal servitude or imprisonment for different periods, according to the degree of the offence. In the United States, by the federal laws, capital punishment is inflicted, in cases within the jurisdiction of the U. S. courts, for treason, murder, arson, rape, piracy, robbery of the mail (if it be with jeopardy to the life of any person), rescuing a person convicted of a capital crime, burning a vessel of war, and corruptly casting away or destroying a vessel belonging to a private owner. The severity of the punishment in the case of rape is because

the offence of which the U. S. courts would have cognizance must be committed on board of a vessel on the high seas or in foreign parts. By the laws of the several states capital punishment is generally limited to three cases, viz.: treason, murder, and arson.—It remains to speak of some principles recognized in criminal law as to the nature of crime in respect to individuals and to the community, the degree of guilt of the person accused, and the rules of evidence by which the offence is proved. I. It is common to divide wrongs into private and public injuries, and it has been erroneously supposed that when the offence is of such magnitude as to become the subject of a public prosecution, the private right is merged. As respects some lesser crimes, as assault and battery, obtaining money by false pretences, libel, and the like, there is a right of private action independent of the proceeding by indictment, and it is not necessary that the individual injured should procure a criminal conviction at all. In cases of larceny, robbery, and other wrongs affecting property, it is generally assumed that there must first be a conviction of the crime before there can be a civil suit for a recovery of the property taken, or damages in lieu thereof. The only reason assigned for this in the English law is, that the injured party may thereby be more strongly induced to procure a conviction of the offender for the benefit of society. It seems, however, not to be admitted in this country as satisfactory. In the state of New York, by statute, the right of private suit is not in any manner affected by the fact that the wrong complained of was a felony (2 R. S. 292). Provision is made by law in England and in the United States for the restoration of property to the owner which had been stolen or otherwise obtained by a criminal act, upon conviction of the offender (21 Henry VIII., c. 11; 2 Rev. Stat. N. Y., 746, § 31); and in the state of New York, redress is given for all other private injuries by a suit against the trustees of the estate of a convicted felon (2 Rev. Stat. 700). In England, as felony worked a forfeiture of the personal estate of the convict, including estates in land for life or a term of years, there was usually nothing to look to as an indemnity for private injury; yet the right of prosecuting for such injury after conviction of the offender is admitted in some old cases; and so after acquittal, if there has been no collusion, an action for damages can be maintained (12 East. 409). II. As to the degree of guilt of the persons accused. This involves several inquiries, the first of which is capacity of mind. There must be the *mens doli capax;* for although ignorance is not in general admitted as an excuse for crime, yet this is to be understood of such only as have sufficient understanding to distinguish between right and wrong. The precise limit of capacity cannot be defined. A vicious life undoubtedly produces hardness and insensibility, and there is often to be seen such natural depravity as is wholly inconsistent with the existence of any moral discrimination. Yet the law does not take into account any such perversity of nature, if there is any intellectual power, which is rather vaguely denominated reason. In what degree this power must exist is not susceptible of being defined by any general rule, and is often the subject of perplexing doubt in the application of the rule to particular cases. Children before the age of discretion are exempt by law from responsibility for crime, but the exact period when such discretion shall be pronounced to commence is not fixed. By the Saxon laws the age of 12 was fixed as the earliest possible development of legal understanding; between that and the age of 14 there might be guilt according to the actual capacity. But the rule of the English law now is, that capacity is not to be judged by age in any case, except that under the age of 7 a child cannot be held guilty of felony; but there is a reported case of a child of 8 years of age who was convicted of arson and hanged; so a girl of 13 was convicted and executed for killing her mistress. In all cases capacity is to be judged by actual proof. Idiocy and lunacy excuse from the guilt of crime. If there was a total want of reason at the time the act was committed, whether the deprivation be permanent or temporary, the law acquits from all guilt; but if there be partial reason, as if there is thought and design, or faculty to distinguish the nature of actions, then there will be legal responsibility for every act. Intoxication is not admitted as an excuse for criminal misconduct. In this respect the rule of the common law is different from that of the civil law. By the latter, capital punishment was never inflicted for acts committed in a state of ebriety. The 2d ground of exemption is where there was no criminal intent, but the act has been committed either by accident, mistake, or necessity. Accident excuses, except where it has happened when a man was engaged in the commission of some unlawful act. A distinction is also made in respect to such unlawful act, as whether it was what is termed by the law *malum in se*, or only *malum prohibitum*, the criminality being less for any accident occurring in the latter case than in the former. There was much good sense in the rules of the Roman law in respect to culpability for accident. Gross negligence was held as culpable as a wrong intent (*non minus ex dolo quam ex culpa quisque hac lege tenetur*). Thus, if a man was lopping a tree near the road, and it should fall and kill a person passing by, he was held guilty if he had omitted to give proper warning. If a soldier exercising in a place appointed for that purpose should accidentally kill a slave by throwing a javelin, he was without fault; but if it had happened in a place where he had no right to exercise, he was held guilty. Mistake is admissible when it relates to a fact, though, as before mentioned, mistake of law is no excuse; as if a person should kill another that he supposed was breaking into his house, and it should turn out to be a member of his own fam-

ily, he would be excused on the ground of having mistaken the person. Necessity, as a legal excuse, includes that class of cases which the law designates as duress. In the English law one other case is also included, viz.: the criminal misconduct of the wife by the command or in the presence of her husband. The reason given in this case is, that the wife is supposed to be under the power of her husband; but a better reason may probably be derived from the old law, by which the husband had the benefit of clergy if he could read, but the wife had not, and the rule was introduced from a motive of humanity. The exemption was allowed only in felonies other than treason and murder, but was not admitted as a defence to a charge of any misdemeanor less than felony. As the reason of the rule does not exist in this country, it may be presumed there is no such exemption other than what may arise from actual coercion. Duress is compulsion by the menace of death or other bodily harm, or by actual force. Blackstone limits the expression "bodily harm" to mayhem, or loss of limb, according to which the fear of being beaten would be no duress, so neither would the fear of imprisonment. In this country, on the contrary, a threat of any bodily harm, or even of the destruction of property, would be held to be a duress in that connection. But when it is set up as a justification for the commission of a criminal act, perhaps nothing less than the fear of losing life, or of some permanent bodily injury, would be admitted as a legal excuse. As to the law relating to principals and accessories, there is less discrimination than is called for by our natural sense of justice, as well as by a due regard to public policy. An accessory before the fact, who is one that has procured or advised the commission of the crime which is the subject of prosecution, is properly held liable in equal degree with the principal for the act which has been committed, and all its natural consequences, but not for another and distinct crime which may have been committed by the principal while engaged in the commission of the offence to which he had been instigated. As if A procures B to beat C, and in consequence of such beating C should die, A is guilty of murder; but if A hires B to beat a man, and he should set fire to his house, this being a distinct offence, A is not indictable for it as accessory. An accessory after the fact is one who, knowing a felony has been committed, receives, relieves, and assists the felon. The rule of the common law, by which even furnishing necessaries to a felon will render a man an accessory after the fact, is unreasonably severe. By statute of the state of New York, only he is held as an accessory after the fact who has aided the criminal to avoid arrest, conviction, or punishment (2 R. S. 699). The criminality of an accessory after the fact is in England and this country deemed less than that of the principal. The punishment is imprisonment only, even if the offence committed by the principal is punishable by death. III. The rules of evidence and mode of proceeding in criminal trials can be but briefly referred to. The most important principle of the English and American law, and what chiefly distinguishes it from the criminal codes of other countries, is that the person accused is not compelled to testify. In the preliminary examination upon arrest, where the arrest precedes indictment, he is indeed allowed to make his statement, and such statement may be used as evidence against him. But he is usually informed by the magistrate that he is not bound to answer the charge unless he chooses to do so. Another rule, which follows naturally from the preceding, is that it is not necessary to prove the guilt of the accused by more than one witness, except in the case of treason and perjury. In the tribunals of some other countries a different rule prevails, because it is the general practice to put the accused under rigid examination; and if he denies the crime, it is an oath in his own favor, which ought not to be overbalanced by a single oath against him. It was the ancient practice in England not to allow the accused to produce witnesses; and when the courts so far relaxed this strictness as to hear witnesses for the defence, it was still without oath, and the evidence was therefore of less weight. But by statute 1 Anne, c. 9, witnesses are required to be examined on oath for the prisoner as well as against him. The privilege of defence by counsel was, until a recent period, denied in the English courts in trials for treason and felonies, while by a strange inconsistency it was allowed in trials for misdemeanor. In cases of treason, which was a class of trials in which there had been the greatest outrage of common rights, relief was given by statute 7 and 8 William III., c. 3, which allowed counsel to be assigned to the prisoner upon his request; and in cases of felony, by statute 6 and 7 William IV., c. 114, by which all persons arraigned upon a criminal charge are allowed to make defence by counsel. In the United States, this right was thought of such importance that it was secured by article 6 of the amendments to the federal constitution, and in the several states a similar provision has been made either by the constitution or by law. In France, the practice formerly was to hold the accused to answer in person without the aid of counsel; but it is now an admitted right that every person charged with a criminal offence is entitled to the aid of counsel for his defence, and it is made obligatory upon the judge to assign counsel when the accused has none. (See *Code des délits et des peines*, art. 187 and 321; *Code d'instruction criminelle*, art. 294, 295.)

CRINOÏDEA (Gr. κρινον, a lily, and ειδος, shape), animals in shape like a water lily, consisting of an expanded or spreading disk upon the end of a long, slender, jointed stem. The name was given by Mr. Miller, author of an elaborate work, entitled "Natural History of the Crinoïdea, or Lily-shaped Animals." They constitute an extinct family of echinoderms of the radiated division of animals, and in the forms of the encrinite and pentacrinite were

wonderfully abundant in the limestones of the silurian period. Their remains now constitute the great portion of the material of strata which extend over large districts of country, and are several feet thick.

CRISPIN AND CRISPINIAN, the tutelary saints of shoemakers, put to death about A. D. 287. The tradition is that they were brothers belonging to a noble Roman family; that, becoming converts to Christianity, they took refuge in Gaul from the persecution under Diocletian; and that they preached the gospel at Soissons by day and exercised the trade of shoemakers by night. They had converted multitudes before their martyrdom under Maximian. Their names are found in the principal early martyrologies, and their festival is observed on Oct. 25. They were the patrons of the religious community of *Frères cordonniers*, founded in Paris in 1645, suppressed in 1789, and which has since reappeared and been dissolved.

CRISSA, an ancient town of Phocis, called "the divine" by Homer. It occupied a beautiful situation at the foot of Mount Parnassus, with lofty mountain heights towering above it, and with the beautiful Crissæan plain spread out beneath it. The modern town of Chryso, occupying the same site, contains some few remains of this interesting city. Crissa and Cirrha were long regarded by scholars as but different names for the same place, but Ulrichs, Leake, and Grote have shown that Cirrha was the port town of Crissa. The taxes which Cirrha levied upon pilgrims on their way to Delphi caused the first "sacred war," which resulted in the destruction of the town. The fate of Crissa itself is not known.

CRITIAS, an Athenian, pupil of Gorgias the Leontine and of Socrates. He was a man of uncommon energy of character, possessed high and varied culture, but was absolutely wanting in moral principle. He was at once politician, poet, and orator. Some fragments of his elegies are still extant; a work of his on politics is sometimes mentioned, and Cicero tells us that some of his speeches, then extant, would place him as an orator by the side of Pericles. The moral instructions which he received from Socrates, however, seem to have produced but little impression upon his corrupt nature. He is now known in history mainly as the cruel and vindictive leader of the 30 tyrants. In that memorable but brief reign of terror which immediately succeeded the Peloponnesian war, he rioted in slaughter and blood. He was conspicuous among his colleagues for rapacity and violence, and punished with death the suggestion of moderate measures. He was slain in an engagement with Thrasybulus, who with his band of patriots marched to the relief of the city (404 B. C.).

CRITO, a friend and disciple of Socrates, whom he is said to have supported with his fortune. He made every arrangement for the escape of his master from prison, and used every argument which ingenuity or affection could suggest to induce him to save his life by fleeing from his persecutors. His eloquence was, however, in vain, and Socrates drank the fatal cup. Crito is a prominent interlocutor in one of Plato's dialogues, which is named after him. He was himself a voluminous writer on philosophical subjects, but all his writings have perished.

CRITOLAUS, a celebrated Achæan demagogue, who incited his countrymen to insurrection against the Romans. He commanded the Achæan army at the battle of Scarphæa, 146 B. C., and when overthrown by Metellus, he either committed suicide or perished in the marshes of the coast.

CRITTENDEN. I. An E. co. of Ark., separated from Tenn. by the Mississippi river; area, 994 sq. m.; pop. in 1854, 3,459, of whom 1,032 were slaves. Its western border is formed by the St. Francis river. The surface is level and alluvial, and part of it often overflowed by the Mississippi. Portions of the land are quite swampy, but the rest is generally fertile. In 1854 the productions were 217,500 bushels of corn, and 1,275 bales of cotton. Capital, Marion. II. A W. co. of Ky., formed in 1842; area estimated at 420 sq. m.; pop. in 1850, 6,351, of whom 848 were slaves. It is separated from Ill. by the Ohio river, and bounded by the Cumberland on the S. W. It has a level or gently undulating surface, except in the eastern part, where it is hilly. The soil is generally good. Hard coal, lead, and iron are found in great abundance. In 1850 the productions were 386,705 bushels of corn, 5,759 of wheat, 45,460 of oats, 505,637 lbs. of tobacco, and 12,545 of wool. There were 14 churches, and 600 pupils attending public schools. Capital, Marion.

CRITTENDEN, JOHN JAY, an American statesman, born in Woodford co., Ky., about 1785. While he was still young, his father, who was a farmer, was killed by the fall of a tree, leaving his mother to bring up, with slender means, a large family of children, among whom several were noted for intellectual ability. Mr. Crittenden commenced life as a lawyer in Hopkinsville, but soon removed to Frankfort, where he enjoyed an excellent practice and won distinction as an advocate. In 1816 he was elected from Franklin county to the Kentucky house of representatives, of which he was for several years speaker. He took his seat in the U. S. senate, Dec. 1, 1817, his term commencing at the same date with the presidency of Mr. Monroe, whom he supported. During his 2 years of service, he moved the reimbursement of fines under the sedition law of 1798, which he pronounced unconstitutional; spoke warmly in favor of a bill introduced by Mr. Morrow of Ohio, which was designed to open the public lands to actual settlers; and as chairman of a committee to whom a house bill, putting fugitives from labor on the same footing with fugitives from justice, was referred, reported it back with several amendments, one of which provided that the identity of the alleged fugitive should be proved by other evidence than that of the claimant. From 1819

to 1835, Mr. Crittenden practised law at Frankfort, occasionally representing his county in the state legislature. President J. Q. Adams nominated him judge of the U. S. supreme court in 1828, but the senate refused to confirm him, and Mr. McLean was subsequently put in his place. In 1835 he was again chosen U. S. senator, served a full term, and was reëlected, but in 1841 resigned, having accepted the post of attorney-general under President Harrison. On Sept. 11 of the same year, with the other members of the cabinet, excepting Mr. Webster, he tendered his resignation to President Tyler in a brief and dignified letter. He was immediately elected to the senate for the residue of Mr. Clay's term, that senator having resigned, March 31, 1842, after the passage of the tariff bill; and Mr. Crittenden was reëlected for a full term from March 4, 1843. In 1848 he retired, having received the whig nomination for governor of Kentucky, to which office he was elected by a large majority. He was attorney-general in President Fillmore's cabinet from July 20, 1850, till the accession of President Pierce. In the spring of 1854 he was induced by long standing relations of friendship with the Ward family to undertake the defence of Matthew F. Ward, indicted for the murder of Prof. W. H. G. Butler in his school at Louisville. This step created at the time much popular excitement against Mr. Crittenden. He had previously been reëlected to the U. S. senate for a term which expires in 1861. In early life Mr. Crittenden belonged to the republican and subsequently to the whig party. He is now called an American. He was one of Mr. Clay's most devoted friends, and supported him in most of those measures with which his name is identified. He has always favored the protective policy, and voted for the tariff of 1842 and against that of 1846. He was for a U. S. bank and against the sub-treasury system. In 1835 he opposed Mr. Calhoun's bill empowering postmasters to take from the mails documents hostile to slavery. He opposed the remission of Gen. Jackson's fine for contempt of court in declaring martial law at New Orleans. The question of apportionment coming up in 1842, Mr. Crittenden favored the smallest ratio of representation, arguing that with more representatives the house would become more democratic. In 1841, a bill establishing a preëmptive system in favor of actual settlers on the public lands being under consideration, he moved an amendment denying the privileges of the act to aliens who had not made a declaration of their intention to become citizens, which he supported in several speeches. Upon the Oregon question Mr. Crittenden spoke often, deprecating haste and excitement, favoring peace, though not at the expense of honor, and supporting such measures as seemed likely to conduce thereto. The same tone runs through his speeches on the annexation of Texas, which he opposed as unconstitutional, unwise, and unnecessary, and on the Mexican war, which he strove to bring to a peaceful termination as soon as practicable. He manifested a similar spirit in 1858 in the debate upon the alleged illegal exercise of the right of search by Great Britain. In 1848 he opposed Mr. Hannegan's bill providing for the military occupation of Yucatan, as subsequently in 1858 he took ground against interference in the affairs of Central America. It was Mr. Crittenden who in 1847 introduced the bill in the senate which authorized the purchase of provisions and the employment of public ships for the relief of the starving in Ireland and Scotland, supporting it in an eloquent and feeling speech. In 1848 he offered a resolution congratulating France upon the successful revolution of February, from which, in common with most Americans, he anticipated the establishment of a lasting republican government in that country. He opposed the admission of Kansas under the Topeka constitution in 1856; voted against the repeal of the territorial laws, and in favor of Mr. Toombs's Kansas bill, on the ground that, however objectionable some of its features might be, it was a measure of peace. In 1858 he opposed the admission of Kansas under the Lecompton constitution, on the ground not only that that instrument did not represent the will of the majority of the people, but that it was a fraud upon them. From his age, ability, and position as the representative of a slave state, as well as from the bold and dashing style of its delivery, his speech on this question carried great weight with it. He subsequently offered a substitute for the bill, which, somewhat modified, afterward passed the house, but was defeated in the senate. It provided for the submission of the Lecompton instrument to the vote of the people of Kansas; if a majority approved, it was to become their constitution; otherwise they were empowered to form a new constitution. Throughout the acrimonious Kansas debates Mr. Crittenden never forgot that he was an American senator, and more than once found himself arbiter of disputes between others. He is sometimes called the patriarch of the senate, a designation to which his character as well as his age entitles him. He has always been considered an excellent extemporaneous debater, and has not yet lost the fire and spirit of his youth. Mr. Crittenden has been twice married; his second wife, who is now living (1859), was the widow of Gen. Ashley of Kentucky.

CROATIA, one of the crown lands of the Austrian empire as reorganized by the fundamental statute of 1849, consisting of the former kingdom of Croatia (a dependency of Hungary), the kingdom of Slavonia, the Croatian Littorale, and the town and territory of Fiume. Croatia (or the 4 counties of Agram, Warasdin, Kreutz, and Fiume) and Slavonia have an aggregate area of about 7,000 sq. m.; pop. in 1851, 878,456; in 1854, 967,136. Croatia is bounded N. by Styria and Hungary, E. and S. by the Military Frontier district, W. by the Adriatic, Illyria, and Styria. It is mountainous, being almost wholly filled up by the continuations of

the Julian and Dinaric Alps. Its principal rivers are the Save, with its tributary the Kulpa, the Drave, and the Mur. The 2 last form the fertile island of Muraköz, area nearly 350 sq. m. The climate is mild and wholesome, at least in the interior. Croatia is poor in natural resources. The grape and chestnut are cultivated extensively, but grain and fruit are grown only in the county of Kreutz and the Littorale. The mountains, although poor in minerals, abound in valuable timber, but very little use is made of it. A fine marble is worked in the Littorale.—The inhabitants, principally Croatians and Rascians or Servians, with a small proportion of Germans, belong with few exceptions to the Roman Catholic church. They are very little cultivated, in fact semi-barbarians. Their idiom is an Illyrian dialect belonging to the S. branch of the Slavic languages. The industry and commerce are scarcely worth mentioning. Wine and timber are the only articles of export to the neighboring provinces. For the domestic trade Agram, Karlstadt, and Old Sziszek are the principal marts. The Littorale has some shipping and ship-building; also several extensive paper manufactories. Public education was in a deplorable state until 1851. Up to that time there was only one school for every 29 sq. m. and every 3,743 inhabitants. Since then, the Austrian government has introduced a complete system of common school education, the results of which are as yet not very perceptible. There are also in Croatia 5 colleges and 2 academies. The province is governed by a ban (governor). Justice is administered by 57 district courts, 4 superior courts, 3 supreme courts, and a court of appeals.—Croatia, which in antiquity formed a part of Pannonia, was a province of the Roman empire from the time of Augustus, being attached to Illyricum. It was conquered by the Goths, recovered under Justinian, invaded by the Avars, and in the 7th century settled by Croats, who after long struggles with the Franks finally formed a vassal state of the Byzantine empire. Toward the end of the 10th century the princes of Croatia assumed the royal title. It was conquered by the Hungarians in 1091, by Venice in 1117, and again by the Byzantines in 1168. Having once more been independent for a century, it was ultimately annexed to Hungary in 1342, and subjected to the Hapsburg dynasty in 1527. In 1848 the hatred of the Croatians against the Magyars made them one of the principal instruments of the Austrian government in crushing the Hungarian revolution.

CROCKETT, David, an American backwoodsman and member of congress, born at Limestone, on the Nolachucky river, in Tennessee, Aug. 17, 1786, died in Texas, March 6, 1836. His father, of Irish birth, after various other avocations, opened a tavern on the road from Abingdon to Knoxville, where David passed his youth from 7 to 12 years of age, making acquaintance with hard times and doubtful characters. He was sent to a country school, but on the 4th day quarrelled with the schoolmaster, and after playing truant for a time in the woods fled from home to avoid a flogging threatened both by his father and master. For 5 years he roamed about the middle states with drovers and carriers, till in his 18th year he returned home, attended school for 2 months, learning his letters for the first time, and soon after married and went to live in the wildest portions of the state, distinguishing himself as a hunter. In 1813 he served in the Creek war under Gen. Jackson, and after the peace settled on Shoal creek, in a desolate region of Tennessee. A community of reckless characters having flocked together after 2 years, it was found necessary to establish a temporary government, and he was appointed one of the magistrates. He soon after became a candidate for the legislature, and though he had scarcely yet read a newspaper he made a successful electioneering tour by the skilful use of his rifle, his companionable habits, and his faculty for telling amusing stories. He was twice reëlected to the legislature, but devoted himself especially to bear hunting, till in 1827 he was elected by the party of Gen. Jackson a representative in congress. At Washington he immediately obtained general notoriety by the eccentricity of his manners and language, and was regarded as a gifted and genial specimen of the "half horse and half alligator." In 1829 he was again chosen to congress, but soon after changed from a partisan to an opponent of Jackson's administration; and in 1831 it required his most strenuous exertions to secure a reëlection. From this time the influence of Jackson became predominant in the West, and especially in Tennessee, and Crockett therefore withdrew from the political arena of the United States. He sought a new career in Texas, then in revolt against Mexico, and after a series of military exploits met his death while bravely defending Fort Alamo, in San Antonio de Bexar. The fort, containing about 140 Texans commanded by Col. Travis and under him by Col. Crockett, was attacked in the latter part of February by a Mexican army numbering 2,000 men. Amid scarcity of provisions and constant watching, shells and assaults were successfully withstood till on March 6 only 6 of the garrison survived. These, including Col. Crockett, then surrendered, but by order of Santa Anna the latter immediately perished with a dozen sword thrusts. The exaggerated stories of his wit and peculiarities afterward made him almost a mythical person. His autobiography was published at Philadelphia in 1834.

CROCODILE, a genus of reptiles which, with the alligator of America and the gavial of the Ganges, constitute the family of crocodilians. Some authors elevate the family into an order, the *emydosauri* of Gray, the *loricata* of Fitzinger, and the *rhizodonta* of Prince Bonaparte, the latter including the large fossil *ichthyosaurus* and *plesiosaurus*. In the class of reptiles they are higher than the saurians, and second to the *testudinata;* among them are included some of the largest, most powerful,

and best protected of their class. The crocodilians, including the alligator and gavials, are characterized as follows: the skin is tough and thick, and protected by firm scales, of different shapes and sizes, forming a coat of mail sword and bullet proof; different species have been distinguished according to their arrangement on the neck; they are square on the upper and under surfaces of the body and on the tail, large and ridged longitudinally on the back, small and rounded on the sides of the body and neck and limbs; on the head the skin is applied directly on the bone, following its eminences and depressions, and unprotected by scales, in this differing from the true saurians; the scales are thinnest below, and of a lighter color, almost white, the upper tints being greenish with dark spots, or an obscure brown. Under the jaw, in the longitudinal folds of the skin, open the ducts of odoriferous glands, which secrete a viscid matter having a strong and disagreeable musky odor; similar pores open near the cloaca. For the details of the skeleton the reader is referred to Cuvier, Meckel, Oken, and other writers on comparative anatomy. The vertebræ are concave anteriorly and convex posteriorly, and are 7 or 8 in the neck, 12 in the back, 5 in the loins, 2 in the sacral region, and from 34 to 42 in the tail; the number is the same in individuals of a species at all periods of life. The vertebræ of the neck have long articulated transverse processes, or cervical ribs, which prevent any extensive lateral motion of the neck; on the under surface of the caudal vertebræ is a series of V-shaped bones, the hæmal arches, for the protection of the vessels. The ordinary ribs are 12 to 13 on each side. The sternum is prolonged even to the pelvis, and gives attachment to 6 or 7 pairs of cartilages, not extending to the spine; these serve to strengthen and protect the abdominal walls, and are represented in man by the transverse lines of the rectus abdominis muscle; the sternum is also prolonged as a point in advance of the ribs; there are no true clavicles, and the bones of the pelvis remain separate. The lower jaw is longer than the cranium, because the condyles of the temporal bones, corresponding to ossa quadrata, are placed considerably behind the articulation of the head with the spine, and are united to the skull as in the turtles; the gape of the mouth is really longer than the extent of the head, from this backward situation of the glenoid cavity. The muscles which move the jaws arise so far back, that they act in part upon the whole head, explaining the assertion made from the time of Aristotle to that of Cuvier, and at various times believed and disputed, that the crocodile has the ability to move both jaws; when the lower jaw is fixed upon the ground, the action of the muscles may raise the whole head, and with it the upper jaw, otherwise immovable. The jaws have no lateral motion, and none from before backward, the articulation being a simple hinge joint. There are no cutaneous lips, the teeth being visible even when the jaws are closed. The teeth are numerous, conical, isolated, unequal in size, hollowed at the base, arranged in a single row, implanted by a true gomphosis in the substance of the maxillary borders in special alveoli directed from before backward, and provided with a kind of gum; the new teeth push up into the hollow of the old, and cause their absorption; the new teeth are larger, but the same in number at all ages. The tongue is flat, wide, fleshy, and attached all around to the jaw bone; it is not divided at the tip, and cannot be extended, being apparent only when the jaws are separated, and forming the floor of the mouth; it cannot be used to seize or retain their prey, nor for respiratory purposes; it is for the most part smooth, except at the base, where irregularly contorted folds are prominent. The nostrils open at the end of the muzzle, near together, and may be closed by valves; their cavity forms 2 canals extending along the cranium, and opening, not into the mouth, as in other reptiles and birds, but into the posterior fauces behind the soft palate, as in mammals; the hyoid bone sends upward a rounded cartilaginous continuation, which can be made prominent at the will of the animal; the soft palate hangs down to meet this, by which the cavity of the mouth can be completely shut off from the fauces; by this arrangement, when the animal is under water, with only the tip of the nose in the air, and even with the mouth filled with water, respiration can be perfectly carried on; and by the same mechanism the act of swallowing can be accomplished beneath the surface. Unlike the saurians, this family have the external opening of the ears protected by 2 folds of the skin, resembling lids, by which the meatus can be closed; the opening is just behind the eyes. The eyes are very small, and provided with 3 lids, an upper and lower, with a third or nictitating membrane moving transversely, transparent, and evidently designed to protect the cornea and permit vision under water; the pupil is a vertical slit, and the crystalline lens almost spherical. The anterior limbs have 5 toes, the external 2 without nails; the posterior limbs are 4 toed, more or less webbed, the external one without a nail; the limbs are so short that they barely raise the body from the ground, and are almost at right angles to the spine; their gait is, therefore, slow and awkward. The tail is longer than the trunk, flattened on the sides, surmounted with crests continued from the back, and serrated below; the powerful muscles of the dorsal region are carried to their greatest development in the sides of the tail, which is the principal organ of locomotion in the water. The stomach is muscular, but in no way resembling the gizzard of a bird; in this cavity are frequently found stones and pieces of wood, which were once supposed to be swallowd intentionally to assist in triturating the food, or

for the purpose of distending the stomach during the season of hibernation which some of them undergo; it is altogether probable that such foreign bodies have been accidentally swallowed during the repasts of the voracious animal. The lungs consist of 3 principal cavities, communicating freely with each other; the walls are divided into innumerable cells, the fleshy compartments of which form a very intricate network, resembling the columnæ carneæ of the heart; when fully expanded, they will contain a large quantity of air. The most interesting organ is the heart, as it shows an approach to, and as it were the connecting link with the birds. In reptiles generally the heart consists of 3 cavities, a ventricle and 2 auricles—the ventricle receiving both arterial and venous blood, and sending this mixed fluid over the system at the same time that it sends to the lungs blood of which a portion has just been received purified from them. In the crocodilians the ventricle has a complete division into right and left, and the circulation is so arranged that while the head and anterior half of the body receive pure arterial blood when the animal is in the air, the posterior half receives a mixed arterial and venous blood; the mingling of the 2 bloods taking place, not in the heart itself, but by an opening between the 2 aortas—a fact unknown to naturalists till the time of Meckel and Panizza. For full details on this point the reader is referred to the "Journal of the Boston Society of Natural History," vol. vi. pp. 113–118. The ordinary course of the circulation would be through the venæ cavæ to the right auricle, thence to the right ventricle; from this more than half of the venous blood goes to the lungs by the pulmonary artery, the rest being distributed to the lower extremities through the left or venous aorta; from the lungs the pure blood comes to the left auricle, thence it passes to the left ventricle, and then by the right or arterial aorta to the head and anterior extremities and body generally, after mixture with the venous blood. In the common circulation, or when the animal is in the air, there would probably be but a trifling, if any, mixture of the bloods through the opening in the aortic wall, and during the contraction of the ventricles the pressure of the valves of the aortæ against the opening would prevent the mingling; but during the diastole of the ventricles, when the valves close to prevent regurgitation into the heart, the aortic opening would be free, and the bloods could mix in whichever direction the pressure was the strongest; the opening, however, performs its special function after the animal has been under water a long time, when there is no respiration nor pulmonary circulation, no blood in the left ventricle, and none sent through the true aorta; were it not for this opening, the head and anterior limbs, which are supplied by the right aorta, would be unprovided with blood; it has been naturally concluded that venous blood is sent through the opening from the left aorta to supply these parts. By its 4 cavities the heart of the crocodilians resembles that of the birds, and also, by the mixture of the blood in the vessels, that of the fœtal mammalia. Meyer compares the left aorta to the ductus arteriosus, and he believes this structure to be a temporary condition, disappearing as the animal advances in age. In the dissection alluded to above, the specimen was 7 feet long, and old enough to be impregnated; the edges were firm and well defined, like those of a persistent foramen; and physiological reasons have been given why it should be permanent in this family, when the respiration ceases during submersion and hibernation. In the males the genital organs are simple; as in turtles and birds, the cloaca is longitudinal. The female alone prepares the hole in the sand in which the eggs, sometimes 60 in number, are placed probably during the night; she covers them with sand and leaves to hide them from the ichneumon and certain reptiles which feed upon them; the eggs are hatched in from 3 to 6 weeks, according to season and latitude. The amphibious habits of the crocodilians are indicated by the nostrils, separation of the posterior fauces from the mouth, shape of the limbs and tail, and structure of the lungs and heart. The crocodiles proper are distinguished from the alligators by their head being longer in proportion to the breadth, by the less number of teeth (30 below and 38 above, according to Cuvier), by the 4th lower tooth on each side being received into a groove in the upper jaw instead of a pit when the mouth is closed, by the dentated crest on the external border of the hind legs in most of the species, by the complete webs of the hind toes (at least the external), and by the larger cranial openings perceptible through the skin behind the eyes. Nothing is more characteristic than the narrowing of the muzzle behind the nostrils caused by the groove just alluded to, added to the perforation of the upper jaw by the 1st lower teeth; the plates of the nape occupy the middle portion only, a space before and behind being without them; as age advances the head becomes very rough. The species are difficult to distinguish from each other, and the variations within the limits of species are considerable. Europe has no crocodile, nor crocodilian, in its present fauna; America has 2, Asia 2, and Africa 1; other species are described, of unknown habitat, and of uncertain characters. The following species will sufficiently characterize the genus: I. The common crocodile of the Nile (*crocodilus vulgaris*, Cuv.), one of the sacred animals of the Egyptians, is mentioned by Herodotus, and well described by Aristotle in his "History of Animals;" the latter also mentions the spur-winged plover, which enters the mouth of the crocodile to pick out and eat the insects attached to the mucous membrane. This species has the widest jaws, 6 cervical plates, the dorsal plates quandrangular with 6

longitudinal series of moderate ridges; cranium rather flat; teeth 66, 36 above and 30 below, the longest being the 3d and 9th of the upper jaw, and the 1st, 4th, and 11th of the lower; 16 to 18 transverse rows of bony plates from the shoulders to the tail, and on the latter from 26 to 38 circles of scales surmounted by a thin, flexible, serrated crest, double for about half its length. The color of the upper surface is olive-green, spotted with black on the head and neck, and marbled with the same on the back and tail; 2 or 3 wide, oblique black bands on each flank; beneath greenish yellow; claws brown. It grows to the length of 20 to 25 feet, and possibly longer. A variety of this (*C. palustris*, Less.), found in Asia, has the head rougher, the scales of the sides, flanks, and upper part of the neck convex and ridged, and the color above olive-yellow, marbled with blackish brown. A 3d variety (*C. marginatus*, Geoff.), a native of southern Africa, has the jaws narrower and elongated, the cranium slightly concave, 6 narrow nuchal plates, the upper parts deep bottle-green, with small brown waving lines disposed in a radiating manner. This variety grows to a large size, and is doubtless the one so often seen by Dr. Livingstone and Mr. Cumming in their journeyings in South Africa. Dr. Livingstone mentions the following facts from personal observation: Sixty eggs have been taken from a single nest; they are about the size of a goose egg, of the same diameter at both ends, white, and partially elastic from having but little lime in their composition and a firm internal membrane; the nests are within a few feet of the water, and are used for successive years if undisturbed; the female assists the young out of the nest, and leads them to the edge of the water, where she leaves them to catch fish for themselves; fish is the principal food at all ages; a wounded animal, or even a man, going into a lake infested by them, is almost sure to be seized; they seldom leave the water to catch prey, but often come out to bask in the sun; they fish chiefly by night, and when eating make a loud champing noise; the natives are very fond of the eggs, eating only the yolk. The Egyptians kept crocodiles in their temples, where they were fed by the priests and ornamented with gold and precious stones; these were highly venerated by the people, and after death they were carefully embalmed and buried with great ceremony; it is very common to find mummies of crocodiles in their tombs, and many may be seen in our museums. The ichneumon, a carnivorous mammal allied to the civets, renders important service to man by destroying the eggs of the Nilotic crocodile. The common crocodile is not confined to Africa, but occurs in Asia, especially on the Malayan peninsula; it is often met with 3 or 4 miles at sea, and has been known to attack boats returning from fishing, and occasionally with the loss of human life. II. The most common Asiatic species is the double-crested crocodile (*C. biporcatus*, Cuv.), so named from the 2 rough lines on the upper jaw extending forward from the anterior angle of each eye; the lateral borders are irregularly convex, and deeply grooved for the lower teeth; the upper surface is very rough, especially in large individuals; the teeth are generally 66, 36 above and 30 below, the largest being the 2d, 3d, 8th, and 9th above, and the 1st and 4th below; the hind legs are as long as the trunk, the fore legs are a third shorter; the armature of the neck consists of 6 shields, 4 in a square, and 1 on each side of these, of an oval shape and strongly crested; on the back are 16 or 17 transverse rows of ridged plates, of an ovoid form; the tail has 38 or 40 scaly rings, double crested for half its length. The color is yellowish green, with black oval spots above. It grows to a length of at least 20 feet. In Gironière's "Twenty Years in the Philippines" (pp. 215–222), is an account of the capture of an immense individual of this species, measuring 27 feet in length and 11 feet in circumference under the arm-pits; the skull of this specimen is now in the cabinet of the Boston society of natural history, and measures nearly 4 feet from the nose to the end of the lower jaw; the head and soft parts attached weighed over 400 lbs. It is found in most of the rivers and lakes of eastern Asia and the Indian archipelago. III. The lozenged crocodile (*C. rhombifer*, Cuv.) of the West Indies has the forehead surmounted by 2 ridges diverging backward, the upper jaw much arched transversely, the jaws narrow, the body thick, the toes and swimming membranes short, the scales of the flanks, sides, and upper part of the neck tuberculated, and the limbs without serrated crests; the sides of the upper jaw are very prominent between the 6th and 11th teeth; the teeth are 64, 34 above and 30 below, the largest being the 2d and 7th in the upper jaw, and the 4th and 10th in the lower; on the nape are 4 small shields in one row, and on the neck 6 oval ridged plates, 4 in a row and 2 behind these; dorsal scales square, in 18 transverse rows. The general color is dark brown above, with zigzag lines of deep yellow, and spots of the same on the flanks and limbs; yellow and chestnut below. It attains a considerable size. IV. The long-nosed crocodile (*C. acutus*, Geoff.) is found also in the West Indies, particularly in St. Domingo, and in the northern parts of South America. It is characterized by its lengthened muzzle, convex forehead, and the irregular disposition of the outer dorsal scales; the hind feet are strongly webbed; on the nape are 2 or 4 shields, and on the neck 6, as in the Nilotic species; the teeth 66, 36 above and 30 below, the longest being the 4th and 10th in the upper jaw, and the 4th in the lower. The color is brown and yellow above, and yellow below. It is said to grow to a length of 20 feet. The *C. cataphractus* (Cuv.) and *C. Journei* (Bory de St. Vincent) form the connecting links between the crocodile and the gavial.—Crocodilians existed in great vari-

ety in former geological epochs, and in countries further north than the present habitats of these reptiles. The most remarkable difference between the fossil and existing species is in the form of the vertebræ; the existing crocodilians have these bodies concave in front and convex behind, and the same is true of the species of the tertiary epoch; but the fossils of the older strata have the vertebral bodies flat, or biconcave, as in fishes, or else the anterior face convex and the posterior concave, just the opposite to the existing forms. Those of the tertiary epoch are generally found in fresh-water deposits, and near the mouths of supposed rivers, so that their habits were then probably the same as now; they have been found as far north as England and France, in Asia, and in the greensand of New Jersey. During the secondary period there existed crocodilians with flat or biconcave vertebræ, resembling gavials in their lengthened cranium; from their stronger armature, more numerous ribs, and the strata in which they have been found, they were probably marine. Among the genera are *teleosaurus* (Geoff.), *mystriosaurus* (Kaup.), *macrospondylus* (H. de Meyer.), *gnathosaurus* (H. de Meyer.), &c., found in the liassic, oolitic, and calcareous strata. Those with an anterior convexity and posterior concavity, of which the type is *steneosaurus* (Geoff.), resembled also the gavials, and have been found in the lias and oolite of England.

CROCUS, a genus of plants of the order *iridaceæ*. There are 2 sorts of crocuses, those which blossom in spring, such as *crocus vernus*, with purple or white flowers and finely netted root coats, and *C. Susianus*, or cloth of gold crocus, with small, deep yellow flowers, the sepals of which are curiously veined with dark, chocolate-brown lines; and those which blossom in the autumn, such as the saffron crocus (*C. sativus*), an oriental plant, cultivated for its long, orange-colored, drooping styles, and the Sicilian crocus (*C. odorus*), whose flowers are fragrant. The saffron crocus blossoms in October, but it is not commonly seen in our gardens. It is, however, extensively cultivated for its produce of saffron in some parts of England. Good saffron consists of the stigmas only, which are small, narrow, and extremely light interior parts of the flower. The crocuses are mostly hardy little plants, and once introduced into the flower borders, they will continue and increase without care.

CRŒSUS, king of Lydia, succeeded to the throne before the middle of the 6th century B. C. Writers of high repute have, however, conjectured that he had already been for 15 years associated in the government with his father, and that many of the events recorded by Herodotus as belonging to his reign are to be referred to this period of joint government. This view is rejected by Rawlinson in the notes to his translations of Herodotus. His reign, according to Rawlinson, extended from 568 to 554 B. C. He ascended the throne in a time of peace and prosperity; he was the heir to untold treasures; success crowned all his early efforts; he subdued the Greek cities on the coast of Asia Minor, formed an alliance with the Grecian islands, and extended his conquests toward the east to the river Halys. He was now a mighty monarch, ruling over 13 nations, and in alliance with the powerful rulers of Media, Babylon, and Egypt; the vast wealth which he had inherited had been increased by the tribute of conquered nations, by the confiscation of great estates, and by the golden sands of the Pactolus. We may perhaps form some idea of the extent of this wealth from the rich votive offerings which he deposited in the temples of the gods. "Herodotus himself saw the ingots of solid gold, 6 palms long, 3 broad, and 1 deep, which to the number of 117 were laid up in the treasury at Delphi. . . . . He had also beheld in various parts of Greece the following offerings, all in gold, which had been deposited in the temples by the same opulent monarch: a figure of a lion, probably of the natural size; a wine bowl of about the same weight as the lion; a lustral vase; a statue of a female, said to be Crœsus's baking woman, 4½ feet high; a shield and a spear; a tripod; some figures of cows, and a number of pillars; and a 2d shield in a different place from the 1st, and of greater size." But in the midst of all his wealth and prosperity, Crœsus began to be alarmed at the rapid conquests of Cyrus, and when at length he saw the Median power fall before the Persian arms, he resolved to avenge his brother-in-law Astyages, the dethroned king of Media. He accordingly crossed the Halys, and offered the Persians battle; but after an indecisive engagement returned to Sardis. Cyrus pursued him, took the city, and made him his prisoner. The Lydian king was condemned to be burned alive, but was finally spared, being saved, according to Herodotus, by recalling a saying of Solon, and became the confidential adviser of his conqueror, whom he survived.

CROFT, William, an English composer, born in Warwickshire in 1677, died in 1727. At the age of 31 he obtained the position of composer to the chapel royal and organist to Westminster abbey, which he held until his death. As a composer of cathedral music he held a high rank. In 1724 he published, under the title of *Musica Sacra*, an edition of his select anthems, 2 vols. folio. Some of these are still performed in the English church service.

CROGHAN, George, an American officer, son of Major William Croghan, and nephew of George Rogers Clark, of the revolutionary army, born near Louisville, Ky., Nov. 15, 1791, died in New Orleans, Jan. 8, 1849. He was graduated at William and Mary college, Va., served in 1811 as a volunteer aide-de-camp to Col. Boyd at the battle of Tippecanoe, was made captain in the following year, and major March 30, 1813. On May 5, 1813, he distinguished himself as aide-de-camp of Gen. Harrison in the defence of Fort Meigs; and on Aug. 1 and 2

he successfully defended Fort Stephenson, at Lower Sandusky (now Fremont), Ohio, with a garrison of 160 men, against the determined attack of Gen. Proctor, with a force of over 1,000, half regulars and half Indians; and this, notwithstanding the fort was so weakly constructed and poorly provided, that he had actually been ordered to abandon it. For this exploit he was rewarded with the brevet of lieutenant-colonel, and 22 years afterward (Feb. 13, 1835) with a gold medal from congress. He was made inspector-general, with the rank of colonel, Dec. 21, 1825, and in that capacity served with Gen. Taylor in Mexico.

CROKER, John Wilson, a British statesman and author, born in Galway, Ireland, Dec. 20, 1780, died at Hampton, near London, Aug. 10, 1857. His father, of English descent, was for many years surveyor-general of Ireland. He was educated at Trinity college, Dublin, where he greatly distinguished himself, especially in the proceedings of the since suppressed "historical debating society." In 1800 he received the degree of bachelor of arts, and was immediately entered as a student at Lincoln's Inn, but remained in Dublin, and was called to the Irish bar in 1802. He devoted his leisure to literature, and published anonymously in 1804 his "Familiar Epistles on the Irish Stage," and in 1805 his "Intercepted Letter from Canton." Both attracted much attention, from the talent and especially the proneness to sarcasm which they indicated. In 1807 he gave another proof of his vigorous ability in an elaborate pamphlet on the "Past and Present State of Ireland," in which he advocated Catholic emancipation. In that year also he entered parliament as member for the borough of Downpatrick, and the tory party soon conceived high expectations from his public life. When, in 1809, charges of maladministration were brought against the duke of York, and a parliamentary inquiry was instituted, Mr. Croker was one of the most effective defenders of his royal highness, and in the long debate which ensued he delivered, on March 14, the best speech that was made on the side of the ministry. He was associated with Gifford, Scott, George Ellis, Frere, and Southey in establishing the "Quarterly Review," the first number of which appeared in 1809, and he continued till his death to be one of the most frequent, powerful, and sarcastic contributors to that periodical. In 1809 the Perceval government appointed him secretary to the admiralty, and he retained that office, fulfilling its duties with unremitting application, till 1830. He sat in the house of commons through 8 successive parliaments till 1832, having been returned for Yarmouth, Athlone, Bodmin, and in 1827 for the university of Dublin. In 1828 he was sworn a privy councillor. He favored the project of Catholic emancipation, was among the first to advocate a state encouragement of the fine arts, and urged the purchase of the Elgin marbles in a speech much in advance of the general treatment of the subject by parliament. An accomplished debater and master of satire, he was a prominent and most resolute opponent of the reform bill, which he believed would ultimately revolutionize the country. The passing of that bill destroyed him politically, for, unlike his comrades, he declared that he never would sit in a reformed parliament, and he never did. He preferred rather the occupation of "tomahawking liberal authors" in the "Quarterly," his contributions to which were so caustic that for many years it was customary to attribute all the most malevolent and ablest articles of that periodical to his pen. He gained the reputation of "a man who would go a hundred miles through sleet and snow, on the top of a coach, in a December night, to search a parish register, for the sake of showing that a man is illegitimate, or a woman older than she says she is." In 1826 he reviewed, in the London "Courier," Scott's "Letters of Malachi Malagrowther," in a way that called forth a delicate rebuke from Scott, who had long been one of his most cordial associates, and who now declined to endanger an old friendship by meeting him in "the rapier and poniard game of wit." Beside his review articles and many pamphlets and printed speeches on political questions, he published poems entitled "Talavera," "Songs of Trafalgar," and several pleasing lyrics, of which the fine lines on the death of Canning are among the most successful; "Military Events of the French Revolution of 1830;" "Letters on the Naval War with America;" "Stories from the History of England for Children," of which over 30,000 copies have been sold, and which Scott in a preface acknowledges to have been the model of his "Tales of a Grandfather." He also translated Bassompierre's "Embassy to England," edited the "Suffolk Papers," the "Letters of Lady Hervey," Lord Hervey's "Memoirs of the Reign of George II.," and Walpole's "Letters to Lord Hertford," and furnished an edition of Boswell's "Life of Johnson" with copious annotations. The last work was received with general approbation, and is esteemed a valuable contribution to literature, though it was severely reviewed by Mr. Macaulay in the pages of the "Edinburgh Review." In return, the harshest and most effective criticism upon the first volumes of Macaulay's "History of England" was from the pen of Mr. Croker. The latter was also long at feud with Mr. Disraeli, who lampooned him in the character of Rigby in "Coningsby," and whose political pretensions, and especially his famous budget of 1852, were consequently assailed with masterly rancor and ridicule in the "Quarterly." He had a controversy with Lord John Russell upon the publication by the latter of the "Memoirs and Correspondence" of Moore, on which he wrote a scathing article, followed by several skilfully written letters in the "Times." Mr. Croker possessed brilliant conversational pow-

ers, a talent for repartee, and a minute acquaintance with the principal questions of politics and belles-lettres. As a political gossip and satirist, he excelled especially in humorously noting the incidents and analyzing the motives of persons and parties at critical seasons of ministerial change. A selection from his numerous contributions to the "Quarterly Review" has been published.

CROKER, Thomas Crofton, an Irish author, born in Cork, Jan. 15, 1798, died in London, Aug. 8, 1854. When 15 years of age he was apprenticed to a merchant, and began to make occasional rambles on foot through the south of Ireland. During these excursions, continued for many years, he made the researches among the peasantry and the collections of legends and songs which furnished the materials for his "Researches in the South of Ireland" (1824), and for his "Fairy Legends and Traditions of the South of Ireland" (1825). The latter work contained several contributions from Maginn, Pigott, Keightley, and Humphreys, which were omitted in subsequent editions, and it was at once highly praised by Sir Walter Scott. In 1819 Mr. Croker had obtained a clerkship in the admiralty, and he was connected with that department till 1850, when he retired with a pension. In 1829 he published the "Legends of the Lakes," and rhymes of a pantomime founded on the story of "Daniel O'Rourke," which were followed in 1832 by the tales of "Barney Mahoney" and "My Village." The two latter are his principal attempts at strictly original composition, his other works being collections of legendary and poetical lore. "My Village" contains minute descriptions, but is written without passion or imaginative power, and was the least favorably received of his publications. The Irish adventures of Barney Mahoney are pleasantly and plainly told. In 1838 he published the "Memoirs of Joseph Holt, General of the Irish Rebels in 1798," and in 1839 he edited the "Popular Songs of Ireland," with historical and personal annotations. He also contributed frequently to magazines, among others to "Fraser's" and the "New Monthly," and was an active member of numerous literary and antiquarian societies. His works give not only the fanciful traditions of Ireland, but also sketches of its romantic features and ruins, and interesting notices of the humors and characteristics of the Irish.

CROLY, George, LL. D., a British clergyman and author, born in Dublin in 1780. He was educated at Trinity college in his native city, and has been for many years rector of St. Stephen's, Walbrook, a metropolitan parish in London. To this position, in which he has obtained an extended fame as an eloquent and impressive preacher, he was presented by Lord Brougham when lord chancellor of England. His literary career began with a poem entitled "Paris in 1815," in which he describes the works of art collected by Napoleon in the Louvre, prior to their restoration to the various galleries of Europe after the surrender of Paris. This was followed in 1820 by the "Angel of the World, an Arabian Tale," and by several satires and lyrics, which were first collected in 1830. His tragedy of "Catiline" appeared in 1822, and though not produced upon the stage was most favorably reviewed by Prof. Wilson, and has maintained its reputation as an admirable specimen of the unacted drama. In 1824 his comedy of "Pride shall have a Fall" was performed at the Covent Garden theatre with great success, which was partly owing to its literary merit, partly to the circumstance that its illustration of the airs and graces of a fashionable cavalry regiment had a direct application at the time, and partly to the extraordinary personation of one of the characters by Frederic Yates. He published in 1827 "Salathiel, a Story of the Past, the Present, and the Future," founded on the legend of the wandering Jew, which is one of his most finished and popular productions. It was followed by two other works of fiction, "Tales of the Great St. Bernard," and "Marston" (1846). The "Modern Orlando (1846), though fragmentary, is one of his best poems. He has made valuable contributions to historical and biographical literature by his "Personal History of King George IV." (1830), his "Character of Curran's Eloquence and Politics," and his "Political Life of Burke" (1840). He has also edited the works of Pope (1835), and the select works of Jeremy Taylor (1838), for which he furnished memoirs and annotations. His publications on professional subjects have been a new interpretation of the "Apocalypse of St. John" (1827), a work entitled "Divine Providence, or the Three Cycles of Revelation" (1834), and numerous sermons on questions of public interest, several of them being upon the Anglo-Catholic controversy. He was one of the early contributors to "Blackwood's Magazine," has furnished critical articles of a high character to various periodicals, and collected in 1842 a volume of "Historical Sketches, Speeches, and Characters." He is reputed an excellent scholar, and his writings are distinguished by a vigorous and imaginative style.

CROMLECH, or Cromlech, a primitive kind of sepulchral monument among the ancient Scandinavian and Celtic nations. It consisted of a large flat stone laid on other stones set upright to sustain it. These monuments are supposed by some antiquaries to have been also used as altars on which sacrifices were offered to the heroes who repose beneath. Though the cromlech and kist-vaen are frequently confounded, they are different in certain respects. The cromlech is open at the side and ends, and larger, whereas the kist-vaen is closed up on every side. The word cromlech is probably derived from the Armoric *crum*, crooked or bending, and *lech*, or *leh*, a stone. By the inhabitants of Wales and Cornwall cromlechs are called *coetne Arthor*, or Arthur's quoits.

CROMPTON, Thomas Bonsor, an English

manufacturer, born at Farnworth, May 20, 1792, died at Sandy, Bedfordshire, Sept. 8, 1858. He was the proprietor of Farnworth mills, and of extensive paper mills at Worthington, near Wigan, supplied the principal newspapers and merchants of London with paper, invented the continuous drying apparatus now in general use, was also an extensive manufacturer of cotton, and for some time the proprietor of the "Morning Post" and other newspapers. Indefatigable in business, he was at the same time an ardent sportsman, public-spirited, a conservative in politics, and noted for his hospitality.

CROMWELL, Oliver, lord protector of the English commonwealth, born at Huntingdon, April 25, 1599, died at the palace of Whitehall, Sept. 3, 1658. His family belonged to the class of English gentry, and his social position was well described by himself, when he said: "I was by birth a gentleman, neither living in any considerable height, nor yet in obscurity." Mr. Forster has printed, from the register of burials of the parish church of Felstead, the entry of the interment of Cromwell's eldest son, Robert, in 1639, in which the Puritan squire is spoken of as a man to be honored; and as this entry was made by the vicar before Cromwell had risen to eminence, the fact is important, as showing the estimation in which he was held by those who knew him best. No such tribute is paid to any other person in the register. The Cromwells were connected with the St. Johns, the Hampdens, and other eminent English historical families. The great grandfather of Oliver was Sir Richard Williams, a nephew of Thomas Cromwell, earl of Essex, whose name he took. His grandfather was Sir Henry Cromwell, who had been knighted by Queen Elizabeth, and who was famous for his charities. Robert Cromwell, a younger son of Sir Henry, married a widow lady named Lynne, daughter of William Steward, of Ely, who was descended from the youngest son of Alexander, lord steward of Scotland, founder of the house of Stuart. Mrs. Cromwell and Charles I. were 8th cousins, and Oliver was three generations nearer to Alexander than was the king whom he supplanted. The income of Oliver's parents was £360 a year, a large sum for those days. Robert Cromwell was a justice of the peace, and sat in one of Elizabeth's parliaments. Mr. Sanford has satisfactorily disposed of the story that he was a brewer by trade. Many curious anecdotes are related of the youth of the future protector, most of which were probably coined after he had risen to distinction. A monkey snatched him from his cradle, and took him to the housetop. A curate saved him from drowning, and lived to tell him that he repented the deed when he was warring against the church. He had a fight when 5 years old with Prince Charles, afterward Charles I., and flogged him, when the royal family was on a visit to his uncle, at Hinchinbrook. A gigantic female figure drew his bed curtains, and told him that he should become the greatest man in England, but did not mention the word king. He was a froward boy, and much given to the ancient youthful pursuit of robbing orchards, and to practical jokes. He took to learning by fits and starts, and, much to the surprise of his master, who had flogged him severely and often, made but little progress. In 1616 he was sent to Sidney Sussex college, Cambridge, where he is represented as having lived a wild life; but as in after days he showed a fair knowledge of Latin, it is to be supposed his studies were not neglected. In 1617, after his father's death, he left Cambridge, and was, according to some of his biographers, entered of Lincoln's Inn. The accounts of his London life are flatly contradictory. One represents him associating with the best company, while the other paints him as a coarse debauchee. His youth was probably spent like that of most men of his class, and was that neither of a saint nor a devil. He was fond of rough sports, such as have generally been pursued by Englishmen. In 1620 he married Elizabeth, the daughter of Sir James Bourchier, and soon afterward his mind took that serious turn which had so great an effect on his life. He is said to have given the best proof of his sincerity by making restitution to persons of whom he had won money. He was an active religious man, prayed, preached, and exhorted with unction, and assisted those of his brother Puritans who needed aid in his neighborhood. He was a member of the parliament which met in 1628, sitting for Huntingdon. During the 11 years that followed the dissolution of that parliament, and while Charles I. was endeavoring to establish a despotism over England, Cromwell lived either at Huntingdon, at St. Ives, or at Ely, his devotional feeling increasing in depth and strength, while his attachment to the country party was deepened and confirmed. There used to be current a story that, in 1638, despairing of his country's welfare, Cromwell embarked for New England, in company with Pym, Hazelrig, and Hampden, but was prevented from sailing by a royal order in council. This is now abandoned, as the ships were allowed to proceed, in consequence of the petition of the passengers and others. The opposition which he made, not to the draining of the fens, but to the interference of government in the work, was successful, and won him great fame, and from the people the title of "lord of the fens," while it showed to the country that he was a man of immovable resolution. In 1640 he was chosen to the short parliament; and when the second parliament of that year was called, Cromwell contested Cambridge with the poet Cleaveland, a zealous royalist, and is said to have defeated him by one vote. Cleaveland is reported to have said that that single vote had ruined both church and kingdom; but this was probably an invention of later times, as in 1640 Cromwell was not so high in general estimation as to be reckoned among the great leaders of his

party, nor was it supposed that that party aimed at any thing which implied hostility to the established order of things in church and state. From the time that he entered the long parliament, Cromwell went with the root-and-branch men, but he was not so conspicuous as to be noted until after the commencement of the civil war. Yet he served on many committees, and took part in debate. Sir Philip Warwick, who heard him speak with heat and earnestness in the first days of the session, felt his respect for the commons lessened because they hearkened much unto him. So little was he known to some noted men, that, on the day he made the speech here mentioned, Lord Digby asked Hampden who the sloven was; and received for answer that, if ever there should come a breach with the king, that sloven would be the greatest man in England. Cromwell was not much given to talk, but he was an active party man, and labored with zeal in the common cause. "It has been ascertained," says Mr. Sanford, "that within the first 10 months of the long parliament, and before the recess, which began on Sept. 9, 1641, Cromwell was specially appointed to 18 committees, exclusive of various appointments among the knights and burgesses generally of the eastern counties. The most important matters fell within the province of several of these committees." He supported the grand remonstrance, and all the other measures of the parliament that were meant to bridle the faithless king. When the war commenced, he became the most active of all men in the field, which he was the first to enter. Before the royal standard was set up he went down into Cambridgeshire, where he had previously sent arms, and formed the nucleus of his "Ironsides," at the same time seeking to give to the forcible resistance that was to be made to the king a systematic character among the leading men of the district, to the end of rendering their military means solidly available. He contributed liberally of his money to the cause. He seized the plate of Cambridge university, which was to have been sent to Charles I., and took the magazine that was in the town. His uncle, Sir Oliver, was a royalist, and the nephew, though he treated him personally with the most distinguished consideration, took from him every thing with which he could assist the king. He was present at the battle of Edgehill. He was made Colonel Cromwell, and acted under the earl of Essex, the parliamentary lord general. He showed himself to be a cavalry officer of remarkable capacity and resource. He would have done much in any contest, for his military genius was of a high order; but the peculiar circumstances of the civil war enabled him to accomplish something that borders on the marvellous. From the first he saw that the parliament could not contend against the king's forces unless it should have in its service men capable of meeting the loyalists on some ground of principle; and against the chivalrous honor that actuated the better portion of the latter, he purposed to direct the religious spirit of the Puritans. Hampden, to whom he unfolded his scheme, thought it "a good notion, but impracticable;" but Cromwell found it no such difficult matter. He raised a cavalry regiment, 1,000 strong, which he drilled and exhorted until it became the finest body of troops in the world, and was the seed of that army which won the parliament's cause, and then overthrew the parliament itself. This regiment was composed mostly of freeholders, or the sons of freeholders, and was recruited from among Cromwell's neighbors, persons who had heard him preach before the war was thought of. Both friends and enemies bear the fullest evidence to the discipline, valor, skill in arms, freedom from military vices, and religious zeal of these Cromwellian soldiers. Their commander told them that they were to fight the king, and said he would himself as soon shoot that personage as any other whom he should encounter in the hostile ranks. This was contrary to the idea and practice of the parliament, which fought the king in his own name, a fiction quite in keeping with English political practice, but which had no hold on the Ironsides, who cheered their colonel's words, and ever acted in their spirit. The early military services of Cromwell were useful, and were soon followed by others of a brilliant character. He surprised a party of loyalists in Suffolk, kept the same party quiet in the eastern counties, and near Grantham totally routed a body of cavalry that was seeking to obtain control of Lincolnshire. His next action was the relief of Gainsborough. The royalists, under Col. Cavendish, were advancing in force upon the town, when Cromwell threw himself in their front. Though the enemy was triple his own numbers, and was drawn up on the summit of a hill, the base of which could be reached only through a gateway in a fence that was commanded by that enemy's fire, he led on his men, charged up hill, and carried the position. Some of the enemy fled, but Cromwell, then exhibiting for the first time that mode of action which gave him so many victories, did not pursue them, but re-formed his troops, and fell upon those who stood, routing them, and driving them into a bog, where they were all butchered, including their general. This victory raised Cromwell's reputation, and the more so that most of the parliamentary generals showed little conduct, and were often beaten. He continued his services in Lincolnshire and the neighboring counties; and parliament ordered that 2,000 men should be added to his command, to be disciplined after his fashion. He was united with the earl of Manchester in command of 6 associated counties, and their forces were joined at Boston, Oct. 1643. Sir T. Fairfax had previously joined Cromwell. Oct. 11, Sir John Henderson, at the head of a superior body of royalist cavalry, came up with Cromwell and Fairfax on Winceby field. A terrible

action followed, in which Henderson was beaten, though his force was three times as numerous as that of the parliament. Cromwell had a horse killed under him, and while rising was himself struck down; but soon recovering, he joined in the battle, and much distinguished himself. After this success, and until the weather forbade further operations, Cromwell continued to act in the field. Parliament made him lieutenant-governor of the isle of Ely, and he was engaged during the winter in raising funds from Peterborough and Ely cathedrals, and from the university of Cambridge, and in reforming the university, 65 fellows being ejected. On Feb. 16, 1644, he was appointed one of the committee of both kingdoms, which was then constituted the executive authority for the conduct of the war, and affairs generally. The campaign of 1644 placed Cromwell clearly before the country. The earl of Manchester and Cromwell joined the army of Fairfax and Leven, and the battle of Marston Moor was fought, July 3, and resulted in the total defeat of the royalists. The victory was principally due to the valor, energy, and coolness of Cromwell and his Ironsides. Cromwell then accompanied Manchester in the march that was made to the south, where things had gone against the parliament. He commanded the horse. The second battle of Newbury was fought, Oct. 27, 1644, the king being with his army. The royalists retreated in the night, though it can hardly be said they were defeated. Cromwell, who had highly distinguished himself in the action, and in the proceedings preliminary to it, vainly entreated of Manchester to pursue. So little energy had that general, that he allowed the king to return, assume the offensive, and carry off the artillery and stores that were in Donnington castle. Manchester was not only listless, but he was a leader of the moderate party, the Presbyterians, who were not for pushing matters to extremity with the king. He did not wish to have the royal army destroyed, as it would have been had Cromwell moved forward with his cavalry as soon as the retreat was discovered. The Independents, of whom Cromwell was the ablest, and who had been little heard of at the beginning of the dispute, were now fast rising to importance in the state and in the army, their growth being not a little stimulated by the conduct of the Presbyterians, who were seeking to establish a tyranny as severe as that of Laud and Strafford, and which would have been unrelieved by any of those embellishments that belonged to the system of the latter. Cromwell determined that the army should pass under the influence of the Independents. He was supported by all the best men of the parliamentary party—Fairfax, Marten, Ireton, Vane, and others. The time had come for energetic action, and Cromwell, from his place in parliament, accused Manchester of backwardness, and of not desiring victory. He narrated all that had happened at Newbury, and bore hard upon the various commanders who belonged to the moderates. Manchester retorted, in the upper house, and, in a narrative that he had written, accused Cromwell of being the cause of the failure of the campaign. He also said that Cromwell was hostile to the peerage, and to the Presbyterian ascendency, which was no doubt the truth. The famous self-denying ordinance was brought before the house of commons, Dec. 9, 1644. It forbade any member of parliament from holding either civil or military office during the war. Cromwell supported it with great plainness of speech, portraying the state of affairs with rough candor, and showing that the want of success was due to the selfish ambition of certain members of both houses, who held places and commands, and who had no wish, therefore, to bring about by vigorous action the settlement of a quarrel the continuance of which they found so profitable. He also pointed out the vices and corruptions that had found their way into the army, to the destruction of its efficiency; and he declared, that "till the whole army were new modelled, and governed under a stricter discipline, they must not expect any notable success in any thing they went about." The first ordinance failed, but a milder one was successful. It provided that members of parliament who then held offices should be discharged. The 3 armies then existing were formed into one, 22,000 strong. Sir T. Fairfax was made lord general, and Skippon major-general. The office of lieutenant-general was not filled up, undoubtedly because it was meant Cromwell should have it, in spite of the self-denying ordinance. The army was entirely new modelled, and many officers were dismissed. Cromwell had been employed, with Sir William Waller, in the mean time, against the royal forces in the west; and when the time came for him to retire, Fairfax sent a petition to the commons, asking that Cromwell might command the horse in his army; and many of his officers signed the petition. The house cheerfully complied, and Fairfax was allowed to employ him for such time as the house should dispense with his attendance. The model had been successful in raising the character of the army, under Cromwell's direction. Before the house had received Fairfax's petition, Cromwell had been several times engaged with the enemy, and had been victorious in every encounter. Matters looked ill for the cause everywhere save in those places where Cromwell was present, and there can be no reason for supposing that Fairfax was not sincerely desirous for his lieutenant's presence, on plain and obvious military grounds. He wrote to him as soon as he received the commons' permission, and on June 13, 1645, Cromwell joined the army at Northampton, the royal forces being 6 miles distant. His arrival caused the army to become active, and he was the real commander of it at once. Causing Ireton to ascertain the whereabout of the royalists, which he did with skill, he declared for

action the next day. Fairfax acquiesced, and on June 14 was fought the battle of Naseby, which was fatal to the house of Stuart. Believing his enemies were retreating, the king was led to abandon an excellent position at Harborough, and to draw up his army on ground favorable to those enemies. The action of Marston Moor was repeated on a larger scale. Portions of each army were successful, but Cromwell held his Ironsides mostly well in hand, and assailed a body of royalist infantry, after he had routed half their cavalry, and so decided the event of the day. The royalists were utterly beaten, 2,000 of them being slain, and 8,000 captured. All their artillery, many thousand stand of arms, a hundred pair of colors, and all the spoil of the king and camp, fell into the hands of the victors. The most important capture was that of the king's cabinet, which afforded abundant proofs of its owner's total insincerity. Cromwell led the pursuit to Harborough, whence he wrote an account to the speaker of the commons of the victory. This letter reached the commons before that of Fairfax, and that was Cromwell's object in writing it so soon. The reading of it was the announcement to the Presbyterians that power had departed from them. Its tone has been called regal, and it was written in the terms of a master. The very day the news reached parliament, the commons resolved that his services should be continued in Fairfax's army during the pleasure of the houses, the lords substituting three months. He followed up the victory with wonderful celerity and success. Leicester was retaken, Taunton relieved, Goring beaten, and Bridgewater stormed. Soon afterward he put down the "club men," a third party, which might have reached to formidable dimensions if they had not been thus firmly dealt with at the outset. After taking Sherburne castle, Fairfax and Cromwell besieged Bristol, which was held by Prince Rupert at the head of 5,000 men. Cromwell, who was ever for bold measures in war, advised that the place should be stormed. This counsel was followed, but the attack failed. It was, however, made with so much spirit that Rupert surrendered, and the soundness of Cromwell's policy was vindicated. He then proceeded against Devizes, which he stormed. Berkeley castle shared the same fate. Winchester surrendered. Basing House, which had previously defied all attacks of the parliamentarians, fell before him. Longford House capitulated at once. He defeated Lord Wentworth at Bovey Tracy, inflicting a heavy loss on him, and taking, among other spoils, the king's standard. He and Fairfax stormed Dartmouth, defeated Lord Hopton at Torrington, and drove the last remains of the western royalists into Cornwall. Finally, Sir Jacob Astley, at the head of 3,000 horse, was routed at Stow-on-the-Wold, March 21, 1646, which was the last action of the English civil war. Sir Jacob was captured, and when taken to the head-quarters of the victors, he said: "My masters, you have done your work, and may go play; unless you choose to fall out among yourselves." Cromwell had indeed done his work, to use an expression of that time, not negligently. He had applied Strafford's idea of "Thorough" in politics to military operations; and nothing like what he had accomplished in less than 10 months from the time he had joined Fairfax at Naseby had been seen in England since the time when Edward IV. crushed the Lancastrians at Barnet and Tewkesbury. The whole of England, as it were, had been subdued, though on the 13th of the preceding June the chances were decidedly in favor of the king, whose cause had been greatly advanced in Scotland by the victories of Montrose. Had Cromwell died in 1646, he would have been entitled to a high place in the list of great commanders. In original genius for war hardly any man ever surpassed him. Yet it was to success in politics that he owed his success as a soldier; for if he had not carried the self-denying ordinance through parliament, the royal cause must have triumphed in 1645. The "new model," emphatically his work, as well as his conception,—he had explained it to Hampden in 1643,—was the cause of the military superiority of the parliament. The time was now come when he was to be as eminent in the cabinet as he had been in the field. Parliament heaped great rewards on him. Lands of the yearly value of £2,500 were conferred on him, taken from the estates of the marquis of Winchester, and from those of the Somersets and Herberts. It was resolved that the king should be recommended to create him a baron. The king had thrown himself into the hands of the Scotch forces then in England, and had been delivered up to the English parliament. The conduct of Cromwell for some time after this event is the subject of much dispute. He is supposed to have stirred up that agitation in the army which was directed against the king, and against any settlement with him, and which Cromwell is charged with only affecting to condemn, though at a later period he visited some of the agitators with military punishment. The army, perhaps the most intelligent body of soldiers that ever existed, appear to have formed a just estimate of the character of the king. They saw he was not to be trusted, and they determined not to trust him; and ultimately they determined to punish him for his attacks on the liberties of England, and for shedding innocent blood. It is not probable that they saw their way more clearly at first than other parties saw theirs, or that they arrived at an immediate conclusion. As in all other cases, events were evolved from events. That Cromwell had something to do with urging on the army to oppose the parliament, is very probable; and the army, in order that it might not be sacrificed by the Presbyterians, who controlled the parliament, seized the king's person, which it held until

late in 1647. If the parliament had dealt honestly and fairly with the army, the troubles might have been brought to an end in 1647, supposing the king to have been capable of dealing candidly with the parliament. It was the dispute between the army and the parliament that encouraged the king so to act as rendered a settlement impossible. Though every one of his schemes had failed, though all his armies had been annihilated, though the Scotch had delivered him up to the English, and though the army of the latter had seized and were holding him, he fell into the sad mistake of supposing that he was necessary to them all, and that he could choose as he pleased with which party to treat. Dominated by an enormous egotism, he set himself to work to outwit Cromwell. That the latter entered into a treaty with the king, and that he was supported by Fairfax and other distinguished soldiers of his party, are indisputable facts. The sincerity of Cromwell in this business is doubted by many; that of the king is believed in by no one competent to form an intelligent judgment. It cost Charles neither difficulty nor pain to deceive, and he seems to have preferred crooked ways, even when it was for his interest to walk in those which were straight. Cromwell's sincerity there is no good reason for doubting. He contemplated the settlement of England on some such basis as the great political dispute was settled 40 years later. His object was a free polity, government by parliament, toleration, the dismissal of the ultra royalists, and the reinstatement of strict legality. That he looked for some individual benefits is true. He was to be lord lieutenant of Ireland, a knight of the garter, and earl of Essex, a title to which one of his family might properly aspire, now that the last of its Devereux wearers was in his grave. Those who accuse Cromwell of hypocrisy in this instance, and assert that he was looking already to supreme power in the state, misjudge his position entirely. He could look no higher than the king professed to be willing to elevate him; and he could propose to himself no higher object than that of settling the kingdom in peace. That he then thought of the throne for himself, under any title, is very improbable. Such an ambition would, at that time, have been quite inconsistent with that good sense which was the prevailing element of his character. He had achieved much, but not sufficient to warrant an aspiration at once so irregular and so lofty, and so contrary to all modes of English thought. Had the king exhibited evidence of honesty, Cromwell would have closed with him, and would have become the founder of a line of nobles; but the most complete proof was obtained by him that Charles was practising the grossest deception, and that instead of a garter for his knee, he intended to decorate his neck with a rope. Then it was that Cromwell resolved upon the king's destruction. The army leaned strongly to republicanism, and contained not a few persons who entertained extreme opinions in religion and politics. Always disliking the king, and convinced of his insincerity, the soldiers saw Cromwell's course with unfriendly eyes. The king sought to cheat every party, and was so weak as to say to Ireton, Cromwell's son-in-law, and who acted with him in all this business: "I shall play my game as well as I can;" to which that stern and honest republican replied: "If your majesty have a game to play, you must give us also the liberty to play ours." The king's "game" became hopeless from the moment he had Cromwell for an antagonist. The king soon saw that he had made one of his mistakes. He believed his life was in danger from the more violent portion of the soldiery, known as Levellers; and Cromwell is supposed to have feared that the monarch would be seized by them, and to have operated on the royal mind, which was also startled by intimations from the Scotch commissioners. Charles, therefore, left Hampton court, in disguise, on the night of Nov. 11, 1647. He took refuge at Carisbrooke castle, in the isle of Wight, instigated by Cromwell. Hammond, governor of the island, was a connection of Cromwell's by marriage. The resolution of the house of commons, not to hold any more treaties with the king, led to much excitement in England, and to some fighting. Cromwell proceeded to Wales, where he put down the royalists with the strong hand. Then came his campaign against the Scotch, popularly called the commencement of the second civil war. The majority of the Scotch were for setting up the king again, and they invaded England with a large army, which was joined by some English cavaliers. Hastening to the north with such rapidity that the Scotch knew not of his arrival, Cromwell effected a junction with Lambert. Their united forces numbered only 8,600 men; the enemy were 21,000. On August 17, 1648, the battle of Preston was fought, and it was Naseby over again. The enemy lost several thousand men in the battle, and the duke of Hamilton, their commander, was among the prisoners. Following up the Scotch with great vigor, Cromwell completed their ruin, so that they were mostly killed, captured, or dispersed. Not in the days of the Edwards and Henrys had the English been more successful over their ancient enemies. Perhaps none of Cromwell's military actions were of a higher order than those of this campaign. They displayed alike daring valor and consummate generalship. The victor pushed on to Edinburgh, where he was welcomed by the extreme anti-Stuart party, headed by the marquis of Argyle. The king's fate was determined by these successes. He had been engaged in his usual "game," and gave further evidence of his bad faith. The army caused him to be removed from the isle of Wight to Hurst castle, where he was civilly treated, but whence escape was impossible. The parliament voted to close with the king,

but the majority were turned out of the house of commons by Col. Pride, or by other soldiers. The king was then brought to Windsor castle, by a detachment commanded by Col. Harrison. The ordinance for erecting the high court of justice was passed, and the king was tried and executed. That Cromwell was at the bottom of these doings there can be no doubt in minds that consider all the circumstances. He was the most powerful man in the state. So far as any one man could be said to rule, he was then the ruler of England. That he acted with free will may be doubted. It may be that he was obliged to comply with the demands of the army, that body being determined that the king should suffer. He may have been urged on by the knowledge he had that the king could not be trusted. His name stands third on the death-warrant of the king, which he signed as a member of the high court. He refused to use his influence to save the king's life. The story that he visited the body, and remarked on the likelihood that the king would in the course of nature have reached to extreme old age, is a melodramatic invention, and to be classed with the scene in Scott's "Woodstock," in which he is represented as going into a fit of delirium on looking at Vandyke's picture of the king. There appears no ground for believing that his conscience ever troubled him for the part he had in that "memorable scene." When the council of state was constituted, for performing the executive duties of government, Cromwell was appointed one of its members. He was made lord lieutenant of Ireland, and proceeded to that country, in much state, at the head of 12,000 men. He reached Dublin, Aug. 15, 1649, and instantly commenced a campaign as brilliant as it was merciless in its character. Drogheda was stormed, and the entire garrison either butchered or sent as slaves to the plantations. Most of the victims were English royalists, and their commander was an Englishman. Cromwell's object was to strike terror into the enemy, and so prevent further resistance. He did not wish to be long absent from England. He was mostly successful, but at Wexford the horrors of Drogheda were repeated; and at Clonmel he met with so stern a resistance that he granted an honorable capitulation. This was owing, not to his humanity, but to his impatience to cross the channel. Appointing Ireton, his son-in-law, lord deputy, he hastened to London, which he reached May 31, 1650, and was received with great enthusiasm. His presence was much needed. The Scotch had set up Charles II., and made a covenanted king of him. They intended to invade England, for the purpose of forcing him on that country. The government of the commonwealth determined to anticipate them, and to send an army into Scotland. Fairfax, being under Presbyterian influence and petticoat government, refused to serve. Cromwell was made general-in-chief, and lord general. He entered Scotland, July 23, at the head of 11,000 men. Lesley, an experienced soldier, commanded double that number of Scotch, and, had he been left free to follow his own will, would have baffled the invaders. He held a strong position between Edinburgh and Leith, and while he refused battle, harassed Cromwell, and destroyed all sources of supply. The country was wasted on all sides, the Scotch following their old modes of resistance to English invasion. There was some fighting, in which the Scotch showed spirit, but generally were beaten. Cromwell was forced to retreat to Dunbar. On Aug. 17 he again advanced, his aim being to cut off the communication between Edinburgh and the western counties; but for this movement Lesley, with the prescience of a true soldier, had been prepared, and he instantly took a new position, not less strong than that which had previously baffled the English. The latter vainly assaulted several posts garrisoned by the Scotch, and occasionally were defeated in affairs of cavalry. The foot had some skirmishing, and there were brisk cannonades. In the end, Lesley won, Cromwell retreating, and the Scotch horse harassing him as his demoralized army, which had suffered much from sickness, fell back once more upon Dunbar, his grand depot and base of operations. In a worse position no army ever found itself than that in which Cromwell had now placed his. Dunbar is in a valley, surrounded on three sides by hills, through which there are but two narrow passes. The Scotch had possession of the hills and passes, and by the labor of a few hours might have shut up the English in a trap. Such was Lesley's plan; but he had in his own camp far worse enemies than he had in that of Cromwell. The preachers were bent upon Cromwell's destruction, and thought it could be accomplished with the sword. Their influence was overwhelming, and, after they had succeeded in driving from the army all the cavaliers in it, they compelled Lesley to lead it into the plain, thus giving up an impregnable position. Meantime, the English in Dunbar, after discussing some desperate expedients, the adoption of either of which would have been an admission of defeat, resolved to send out a strong column to the right on the morning of Sept. 3. This column marched, and fell in with the Scotch, who had just descended from the hills, whereupon the battle commenced. The result was doubtful, as between the infantry, until a body of English cavalry came to their countrymen's assistance, and so the Scotch were routed, their very excess of number causing their defeat to be the more complete. On the other wing, and in the centre, the English were also successful. The vanquished lost 12,000 men, mostly prisoners, all their artillery, 200 colors, and 15,000 stand of arms. Like Inkermann, Dunbar was the soldiers' battle, being won by hard fighting, and without any generalship on the part of the victor, who frankly disclaimed

all merit, and who had put his men in a position where nothing could save them from destruction save the folly of the enemy. Advancing for a third time into Scotland, Cromwell took Edinburgh, the castle of which held out until Dec. 24. The winter was passed in political intrigues and in some military operations in the southern districts. In the spring, when about to take the field in force, he was seized with ague, and was not able to act until July 1, 1651. Lesley had done his best to reorganize his army, and though much harmed by the continued interference of the preachers, he baffled Cromwell for some weeks. The latter, by a bold manœuvre, sent a corps into Fifeshire, which defeated the Scotch there, and the consequence was that the English were enabled to besiege and take Perth. While thus engaged, Cromwell learned that the enemy had marched into England, which course had been taken by Charles II. in the belief that he should be joined by the English cavaliers, and the people generally, almost all of whom were opposed to the new government. The Scotch reached Worcester, where they halted; but if they had pushed on to London, it would have fallen into their hands, and with it the whole country. The prompt and skilful measures taken by Cromwell on hearing of Charles's march had brought 30,000 English troops to the vicinity of Worcester, including regulars, train bands, and militia. The king had but 13,000. On Sept. 3, the anniversary of Dunbar, the battle of Worcester was fought, and ended in the annihilation of the invaders, 2,000 of whom were killed, and 8,000 captured. Cromwell believed it to be "a crowning mercy," as it was, for it was fatal to the royal cause; and had the victor not died prematurely, or had his successor been a man of talent, a new dynasty, if not a new polity, would have been set up in Britain. It is related, as an evidence of his elation after the battle, that he offered to knight some of his officers. The government showed itself most grateful, not to say servile, to the victor. An estate of £4,000 a year was conferred on him, and Hampton court was prepared for his abode. He was made chancellor of the university of Oxford. Sept. 3 was ordered to be observed annually "for all time to come,"—which the event showed to be 8 years. But nothing short of supreme power would content him. He was determined to be master of all. His demeanor changed, and he bore himself as Cæsar is said to have done after he had struck down the last of his open enemies. He was determined to settle the state, but in his own way, and with himself as its chief. In 1647 he would have been content with the highest honors of a subject, could he have relied upon the king; but in 1651 he had put the king to death, had conquered Wales and Ireland, had won three of the greatest battles of that age, and had driven the whole Stuart family from all its dominions. With the increase of his influence and power his political horizon had extended. Unquestionably he aimed at the throne, not from any love of the mere trappings of monarchy, to which his robust nature was indifferent, but because he knew that the kingly office and title were grand elements of strength. He wished to be a liberal, constitutional monarch, and had he been met in his own spirit such a monarch he would have become. But he encountered opposition from many who had thus far acted with him, and the soldiery themselves, attached though they were to his person, and ready to do most of his work, were sincerely devoted to republicanism. With their consent he might be any thing he chose but king. The best of the republican statesmen, headed by Vane, were for maintaining the existing order of things; and they were right, the government that existed since Charles I.'s execution having proved itself worthy of trust, and having managed the internal affairs of the state, and its foreign policy, with a vigor and a prudence that had not been known since the death of Elizabeth. Could Cromwell have been content with a just share of power in the new government, it would have been maintained; and as the new system would then not have depended on the life of one man, the royal family would have been kept out for ever. But he was bent upon being sole ruler. The 19 months that followed the final overthrow of the royalists were spent in discussions and intrigues, and they constitute the least reputable part of Cromwell's career. On April 20, 1653, he drove the remnant of the long parliament out of the house of commons by force. The council of state was broken up the same day. For some weeks England was as near to an anarchy as any civilized nation has ever been; but on June 6, Cromwell issued summons to 156 persons to meet at Westminster, as a parliament. All but two obeyed, and the new parliament met July 4. This was the famous Barebone's parliament, which has been a by-word for two centuries. One of the members was named Barbone, and this was scurrilously changed into Barebone. All but 17 of the members were summoned for England, Ireland and Wales having 6 each, and Scotland 5. Cromwell made to this body a long speech, and resigned his power into its hands. The parliament was a well-meaning body, but it contained few men of influence, and its conduct, though honest, only added to the public confusion. On Dec. 12, a portion of its members resigned their power into the hands of Cromwell, and the rest either retired silently or were driven out by soldiers from their hall. On Dec. 16 came forth the new institute of government, by which Cromwell was made lord protector, and the supreme legislative authority was vested in him and a parliament. The parliament was to be imperial in its character, and not to exceed 400 members for England, 30 for Scotland, and 30 for Ireland. The protector was to be assisted by a council of state. There

were many judicious provisions in the institute, among which was an improvement of the representation, similar in principle to that which was adopted by England in 1832. Parliament was to meet in Sept. 1654, and until that time the protector and his council were to have unlimited power. Cromwell was to hold office for life, and the council of state was to choose his successor, but at a later period Cromwell was authorized to name him. So far as he could, the protector revived monarchical forms. A variety of ordinances were passed of an arbitrary character, and many of the government's deeds would have disgraced the worst times of the Stuarts. Cromwell's defence is the necessity of the case, which must pass for what it is worth. There was no lack of vigor in the government, and though the protector did all that he could to conciliate the royalists, which was not much, he found them inveterately hostile, and their baser spirits bent on assassinating him. A plot was detected in 1654, and two of the conspirators were executed. Following the course of the government he had overthrown, the protector's foreign policy was bold and manly, save that in making peace with the Dutch he abandoned the high position which the statesmen of the commonwealth had assumed, though the war had been successful. A favorable treaty of commerce was made with Sweden. Parliament met Sept. 3, 1654. Care had been taken to exclude from it men whose hostility to the protectorate was supposed to be unchangeable, and no man who had been on the royal side in the civil war was even allowed to vote for members. Still some inveterate republicans were chosen, and Bradshaw, their leader, moved for a committee of the whole to deliberate whether the house would approve of the new system of government, which was carried. Warm discussions followed, upon which the protector locked the members out of their hall, and would allow none to return to it who would not sign an engagement that the government was legal. Nearly two-thirds signed, but the rest refused; but the servile majority soon fell to questioning the "institute," and government was in a minority, whereupon Cromwell dissolved the parliament. A despotism was established, followed by both royalist and republican plots, which failed, and many of those engaged in them were punished. Numerous arrests were made of persons not even suspected of crime, the object being to strike terror into the public mind. The royalists were very harshly dealt with. England and Wales were divided into 12 districts, the military command in each being vested in a major-general. Beside having control over most of the ordinary affairs of life, the commissions of these officers contained a special order from the protector that they should observe and follow such directions as they should from time to time receive from him. Never before or since has England known so iron a rule, and to the wrongs that were common under it must be attributed not a little of that folly which, 5 years later, brought about the restoration without any thing having been done to secure the rights of the people. To atone for this denial of freedom to his subjects, the protector gave them glory. France and Spain contended for the English alliance, and France succeeded. The Spanish possessions in America were assailed, and Jamaica was taken. Admiral Blake was successful in the Mediterranean, against the Barbary powers and Tuscany. The influence of England put an end to the massacre of the Vaudois. Rich spoils were taken from the Spanish fleets. Appeals were made to Cromwell for assistance from various states. These proceedings were expensive, and funds ran so low that it became necessary to call a parliament, to meet Dec. 17, 1656. The elections caused much excitement. To prevent their return, eminent republicans were imprisoned. But the majority was adverse to Cromwell, who thereupon excluded more than 100 of them from the house. Wishing to gain popularity, he allowed parliament to put an end to the power of the major-generals. It was moved that the protector should take the title of king, and, after much debating and intriguing, this was carried, as were some other provisions calculated to restore the old English polity. Cromwell longed for the crown, but he dared not accept it against the determined opposition of some of the highest military officers, and the general sense of the army. He accordingly refused the offer. The other provisions were adopted, and the lord protector was newly inaugurated, with great pomp and solemnity. Parliament adjourned, to give him time to create a house of lords. When it reassembled, the excluded members having been restored, the commons refused to recognize the other house, and Cromwell dismissed this, his last parliament, his last words to it being: "Let God judge between me and you!" to which some of the republicans answered: "Amen!" The brief remainder of his life was passed amid plots, having his murder for their end. He had such good intelligence that every thing became known to him, and the plots uniformly failed. Yet the precautions he had to adopt were of a humiliating character, and resembled those of the Greek tyrants. He was much in need of money for the public service, but he dared not impose taxes by his own authority. Meantime his foreign policy went on successfully, the bonds of alliance between England and France being of the strongest nature. English forces fought side by side with the French against the Spaniards, the latter having some of the banished English cavaliers under their banners. Cromwell told the men of the army he sent to Louis XIV.'s aid that they were to show the same zeal for the monarch that they showed for himself; and Louis and his minister (Mazarin) evinced their attachment to Cromwell in various ways. Had the protector lived, he would probably

have found the means of carrying on his government. Another parliament was thought of, from which the republicans were to be excluded, and Cromwell's last public act was to dissolve the committee that had the subject under deliberation. In the summer of 1658 his 2d daughter, Elizabeth Claypole, died; and as she was his favorite, and his disposition was affectionate, the effect on his shattered body and disturbed mind was serious. After some previous illness, he was forced to confine himself to his room, Aug. 24, 1658, from a tertian fever. On Sept. 3, the anniversary of Dunbar and Worcester, and known as his "fortunate day," he died, at 4 o'clock in the afternoon, and in the midst of the most terrible storm of those times, which both friends and enemies connected with his death, but with different associations. The remains of the protector were soon consigned to Henry VII.'s chapel, as it was impossible to keep them, corruption having followed death immediately, with singular rapidity and violence; but the public funeral, a gorgeous ceremony, took place Nov. 23. After the restoration, his body was disinterred, and gibbeted at Tyburn, and then buried under the gallows, the head being placed on Westminster hall. There was long current, however, a story that the protector's body, by his own directions, was buried in Naseby field, at midnight, in a grave 9 feet deep; and in itself this story is not improbable, but it was coupled with the assertion that the body gibbeted at Tyburn was that of Charles I., which was discovered at Windsor in 1813, so that the tale can no longer be regarded as true, though it is with reluctance that its want of foundation is admitted.—Cromwell had 5 sons: Robert, born 1621, died 1639; Oliver, born 1623, died in battle, 1648; James died in infancy; Richard and Henry survived him. He had 4 daughters: Bridget, married, first to Ireton, and then to Fleetwood, a woman of decided character, died at the age of 57, in 1681; Elizabeth, born 1629, married to John Claypole, died 1658; Mary, born 1637, married to Viscount (afterward earl of) Fauconberg, died 1712; Frances, born 1638, married, first to Robert Rich, 1657, and, Rich dying in a few months, then to Sir John Russell, died 1721. The wife of the protector survived him 14 years, dying Oct. 8, 1672, after having lived in retirement since the downfall of her family.—There are many lives of Cromwell, the best of which for general readers is that to be found in Mr. Forster's "Statesmen of the Commonwealth of England." Mr. Carlyle's "Oliver Cromwell's Letters and Speeches" is a work of great excellence, but the author's purpose of seeing no wrong in his hero's conduct lessens its value. Mr. Gleig's "Lives of the most eminent British Military Commanders" contains a good military biography of the protector. Most of the other biographies are worthless, either from the ignorance or the prejudices of their authors. Clarendon's great work has always been popular, and it bears hard upon Cromwell. Even the able volumes of M. Guizot, who has gone over the whole 35 years from the accession of Charles I. to the restoration, are tinged with his peculiar views, and are not always just either to the statesmen of the long parliament or to Cromwell individually; but they contain much matter not to be found elsewhere. Mr John Langton Sanford's "Studies and Illustrations of the Great Rebellion" contains much valuable matter concerning Cromwell, admirably told, but it terminates with the battle of Marston Moor. It corrects many errors in Cromwell's history that have long been received as truths.—Richard, 3d and eldest surviving son of the foregoing, and second lord protector, born at Huntingdon, Oct. 4, 1626, died at Cheshunt, near London, July 12, 1712. He became a student of Lincoln's Inn, 1647, where he remained 2 years. He did not study much, but devoted himself to the pleasures of the field and the table, to the former of which he had become attached while leading a rural life in the early years of the civil war. In politics he is said to have been a royalist, and to have interceded with his father for the king's life. In 1649 he married Dorothy, daughter of Richard Mayor, of Hursley, where they resided during most of Oliver's protectorate, Richard indulging in hunting and hospitality. Oliver did not think highly of his son's capacity, and was pleased to see him remain in the country. When the protectorate was established, Richard was elected to parliament, for various places, on different occasions, and Oliver endeavored to train him to the art of government. He succeeded his father as chancellor of Oxford university, was made a colonel, and a lord of trade and navigation. When the protector sought to create a house of peers, his eldest son was placed at its head, with the title of the Right Hon. Lord Richard, &c. On Oliver's death, Richard succeeded to the place of lord protector as regularly and as easily as Charles I. had succeeded James I. A parliament was called, which met Jan. 27, 1659, to which he made a sensible speech, and for a short time things went on well. In parliament, however, he was not strong, and the army was not attached to one who was at heart a royalist. A meeting of the officers was held, at which it was resolved that the army should be commanded by some one person. The protector applied to parliament for advice, at the suggestion of the council; and that body condemned the action of the army, and declared that the officers should hold no more meetings without the protector's permission. This brought matters to a crisis. The officers compelled Richard to dissolve parliament, which event was soon followed by his own resignation. He was not equal to the place in which circumstances had placed him. To the remonstrances his determination excited he replied that his resolution was fixed, that violent councils did not suit him, and the like. His retirement drew upon him

reproaches from all sides, which have been repeated for two centuries. Even Macaulay speaks of him as "that foolish Ishbosheth," who could not preserve "an authority which any man of ordinary firmness and prudence would have retained." Just before the restoration, the Cromwellians wished to replace Richard at the head of the nation, but it was too late for such an act to be attempted, even if he had himself been willing to return to Whitehall. He retired to Hursley, his wife's estate, that lady feeling far more the fallen condition of the family than her husband. In July, 1660, he left England for the continent, but less on account of political than for personal reasons. His debts amounted to £30,000. He resided at Paris, under the name of Wallis, for 20 years, making two visits to Geneva. He was little known, and sometimes had his feelings wounded by expressions of contempt for his poltroonery from strangers. He returned to England in 1680, his debts having been paid, took the name of Clarke, and resided at Cheshunt. His life was retired. One of his few friends was Dr. Watts, who never heard him mention his former greatness more than once, and then indirectly. A lawsuit with his daughters, in his extreme old age, brought him before the public, in the reign of Queen Anne. The judge treated him with much consideration, and his conduct was approved by the queen. Richard won his cause. He lived to be nearly 86, dying at Cheshunt, in the house of Sergeant Pengelley, who was supposed to be his natural son, and who rose to eminence in the law. He was buried in the chancel of Hursley church, where one of his daughters erected a monument to his memory. He left no legitimate son. His son Oliver, who appears to have been a man of some capacity, was active in the revolution of 1688–'9, and offered to raise a regiment to serve in Ireland, provided he were allowed to nominate his captains; but the name was yet too formidable to warrant government in accepting the offer. He died May 11, 1705.

—Henry, 2d surviving son of the first lord protector, born at Huntingdon, Jan. 20, 1628, died March 23, 1673. He was educated at Felstead, but as he entered the parliamentary army at the age of 16, he could not have known much of schools. Before he was 20 he had a troop in the lord general Fairfax's life guards. He was made a colonel in 1649, and went with his father to Ireland, where he served throughout those fierce wars that subjugated the country, distinguishing himself on several occasions. In the first parliament that his father called, the "Barebone's parliament," he sat as one of the 6 Irish members. He was married, in 1653, to Elizabeth, daughter of Sir Francis Russell, a lady of whom much that is good is reported. The university of Cambridge elected him to parliament in 1654. In 1655 he was sent to Ireland as a major-general, and eventually he was made lord deputy. He was well received in that country, and he justified the reception by the admirable manner in which he governed it. Men of all parties united in praising his wise and benevolent action; and Ireland rose rapidly to prosperity under his rule. He is said to have inclined in politics to royalist principles, which was not uncommon with members of Cromwell's family. When Oliver died, Henry exerted himself to have his brother's authority acknowledged in Ireland, and with entire success. The troubles that befell Richard in England, however, soon had a prejudicial effect on Irish affairs. Henry was annoyed in various ways by his brother's enemies, and he sought to throw up the government of Ireland, in order that he might reply to attacks that had been made on him in England, and to assist the protector. His request was refused, probably because the republicans feared him, well knowing that he was a very different man from Richard. When the protector retired, Henry resolved to place the Irish government in the hands of Charles II.; but the long parliament recalled him, and placed the government in the hands of commissioners. He obeyed the summons, and parliament expressed approbation of his conduct. So poor was he that he had not money enough of his own to pay his expenses from Dublin to London. The readiness with which he surrendered his government does not confirm the common impression that if he had been appointed his father's successor, he would have maintained the place. He lacked ambition. Henry resided for some years with his father-in-law, Sir. F. Russell, at Chippenham. Thence he went to a retired estate of his own, called Spinney Abbey, near Soham, Cambridgeshire, where he passed the remainder of his days in farming. Charles II. is said to have visited his house when going from Newmarket to London; and when he heard that Henry was suffering from the stone, he expressed sympathy with him, and, according to one account, even prescribed for him, the king being a dabbler in medicine. It was of this complaint that Henry died. He was buried in Wicken church, and a stone was placed over his remains, with a Latin inscription, stating merely the place of his residence, his age, and the dates of his birth and death. He had 7 children. His last male descendant, and great-grandson, died in 1821, at Cheshunt, aged 79. He had been a solicitor, and was the last representative of the great protector.

CROMWELL, Thomas, earl of Essex, born toward the close of the 15th century, died July 28, 1540. The exact date of his birth is unknown, though one account says he was born in 1498. His father, one of the Lincolnshire Cromwells, moved to the capital, and had an iron foundery at Putney. The name of his mother is nowhere given, but she is called a gentlewoman by some writers. Cromwell's father died when the future statesman was very young, and the accounts that are given of the orphan's early days are unworthy of confidence. He is said to have been a clerk at Antwerp, and to have been one of a party which went

on a private mission to Rome. The first clear sight of him represents him a ragged youth in the streets of Florence, in 1515, where he attracted the attention of Frescobaldi, then a great banker, and having extensive business connections with England. To his inquiries, Cromwell stated who he was, and that he had been page to a French foot soldier. Frescobaldi took him to his house, relieved his wants, and furnished him with the means of returning home. He found his mother, who had married a second time, again a widow, and he carried on his stepfather's business, that of a clothier. This brought him into connection with the court, as he furnished the royal liveries. He had some employment in the household of the marchioness of Dorset, and finally passed into the service of Wolsey, who saw his talent, and as early as 1525 employed him to visit and break up certain small monasteries, the property of which had been granted by the pope for the foundation of colleges. There is a story that Cromwell was with the army of the constable Bourbon, which took Rome in 1527; but if it has any foundation, he must have been in Italy as an agent of the English government, and not as a military adventurer; for he was with Wolsey not 4 months before Rome was stormed, and again less than a year after that event. Another story is, that he saved the life of Sir John Russell, at Bologna, for which there appears to be some foundation. He remained with Wolsey until the cardinal's ruin, and contended so ably in the house of commons against the bill of impeachment that had been preferred for the completion of the minister's fall, that he caused it to be thrown out. This fidelity to his patron won him great applause, including that of Henry VIII., who could appreciate generosity in others if he could not practise it himself. His talents, too, must have recommended him to the king, who made him his secretary in 1533, and government organ in the house of commons. This necessarily made him the leader of the English reformation, a part for which his early life is supposed to have prepared him. Froude assigns to him the honor of being the only man in England who saw his way distinctly through the chaos of that time, the privilege of genius, that of seeing what other men could not see, being his. He had no party; he was despised and feared by the nobility, who saw in him the friend and pupil of Wolsey, Wolsey's genuine successor in the race for power; while the Protestants could not understand either the character or conduct of the man who was doing their work better than they could do it themselves. But his power rapidly became great, and for several years he was, after the king, the most powerful man in England. In 1531 he was concerned in obtaining from the clergy the enormous sum of £118,000, a fine for their having supported Wolsey's legantine authority. Promotion rapidly followed his entrance into the king's service. He was knighted, sworn of the privy council, and appointed to several offices. The high posts of secretary of state and master of the rolls soon followed, and he was elected chancellor of the university of Cambridge. In 1535 he was created vicar general, or visitor general, with power to visit all the monasteries in England, and issued a commission for a general visitation of the religious houses, the universities, and other spiritual corporations. He did not become vicegerent in ecclesiastical matters until July, 1536, having just previously been created Baron Cromwell, and lord privy seal. The visitatorial power was executed with great vigor, the other side said with great cruelty and gross injustice. The proceeding was one of the first importance, and struck a deadly blow at the ascendency of Rome in England. The king was satisfied with Cromwell's proceedings, and the work of the reformation was much advanced. Sweeping changes were made in the religious system of England. The articles that were adopted by the convocation of 1536 were not acceptable to either Protestants or Catholics, but government, of which Cromwell was chief minister, was strong enough to enforce them. The complete edition of the English Bible, known as the "Great" or "Crumwell," was published 3 years after, with the arms of Cromwell on the title page. The minister, though he was regarded by the nobility with the deepest aversion, as an upstart, was now at the height of his power, which he maintained for some years, continuing to receive rewards and promotion from the king. He was appointed justice of the forests north of the Trent, made a knight of the garter, and elevated to the dignity of lord high chamberlain, receiving at the same time the title of earl of Essex. He was created constable of Carisbrooke castle, and received the castle and lordship of Okeham, together with valuable estates made up from the possessions of the dissolved monasteries. The reforms he effected were extensive, and in many instances they were useful, and of lasting value; but the readiness with which he accepted so large portions of the spoil that had been created by the success of his policy must ever be a stain on his memory. His appointments and titles, too, gave much offence in influential quarters. One great family was mortally offended by his taking the title of lord high chamberlain, and another by his elevation to the earldom of Essex. The people hated him because of the taxation with which he burdened them. He had enemies on all sides, and friends nowhere. The fluctuations of Henry's mind were such that no reliance could be placed on the royal support, the king sacrificing his instruments with even more than the proverbial readiness of despots. The party hostile to him—headed by the duke of Norfolk and Gardiner, and Catholic in doctrine, but compelled to submit to the new order of things by the iron energy of the king—was continually on the watch to entrap him; and toward the close of his career they had much

encouragement from the king, who is said to have treated his chief minister to harsh words and hard blows. Cromwell daily became more identified with the Protestants, partly from conviction and partly from circumstances; and this must have rendered the king hostile to him, for Henry was to the last a Catholic in all great essentials, and merely wished to be his own pope. It is not probable, therefore, that Cromwell could have much longer maintained his position, even in a contest confined to domestic politics; but an incident bearing upon foreign policy occasioned him to fall rapidly. With the view of connecting England with the Lutherans, he had promoted the marriage of Henry with Anne of Cleves. The lady was very pious, very virtuous, and very unprepossessing. Henry was disgusted with her, and refused to regard her as his wife. An attempt to form an Anglo-German league failed, and Henry was left alone at the very time when Charles V. and Francis I. were drawing together, and the Lutherans were deluded by the emperor. Cromwell continued to protect the Protestants, and only a few days before his fall he sent a Catholic bishop to the tower. On June 10, 1540, he was arrested, on the charge of high treason, while sitting at the council board, and sent to prison. Parliament was in session, and a bill of attainder was soon passed. The only friend Cromwell found was Cranmer, who desired he should be spared. The prisoner made a pathetic appeal to the king, who was moved by it, but would not pardon him. He was beheaded July 28, suffering cruelly at the hands of an unskilful executioner. Government had the baseness to place in his mouth a dying speech that he never made, but which has passed into history, so that he was represented to have died in the faith of that church which he had done so much to overthrow in England. There are few great men of whom so little is accurately known as Thomas Cromwell. He played for 8 years the highest part in England, and in one of the most fruitful of revolutions. He stamped his mind on the English constitution in church and state. That he was guilty of many acts of injustice and cruelty is indisputable, but his memory is entitled to the plea that he was placed in a position where no man could have preserved his virtue. The best account of Cromwell is to be found in Mr. Froude's "History of England from the Fall of Wolsey to the Death of Elizabeth." Cromwell was married to a lady of the name of Williams, by whom he had one son, Gregory, who was made Baron Cromwell of Okeham, at the same time that his father was created earl of Essex. This son was married to Elizabeth Seymour, a sister of Henry VIII.'s third queen. The posterity of this couple long enjoyed the title of Lord Cromwell.

CRONSTADT, or Kronstadt, the most important seaport and naval fortress of Russia, the seat of the admiralty, and the station of the Baltic fleet, is situated in the S. E. part of a small, arid, and rocky island, called Kotlinoi Ostrov (Kettle island), at the E. extremity of the gulf of Finland, opposite the mouth of the Neva, in the government, and 20 m. W. of St. Petersburg; pop. in winter, when the harbor is deserted and ice-bound, about 10,000; in summer, including the garrison, sailors, workmen, and students, sometimes 60,000. The town was built by Peter the Great in 1710, the island having been conquered from the Swedes in 1703 by Mentchikoff, while Charles XII. was engaged in his Polish campaign; it received its name in 1721, was fortified during the same reign, and subsequently under Elizabeth, Catharine II., Paul, Alexander I., and Nicholas, being destined from its foundation to become the great bulwark of the new Russian capital, and a chief naval stronghold of the Baltic. The southern channel, which separates the island from the mainland, is narrow and commanded by a small fortified islet, and allows single vessels only to pass; the opposite channel, the broader, but from its sand banks still less practicable entrance to the shallow eastern bay, called the bay of Cronstadt, is commanded by the batteries of the rock of Riesbank, and the citadel of Kronslott, situated on 2 small islands. Numerous forts and batteries defend all other parts of the island, which forms an irregular triangle, having its base toward St. Petersburg. Near its N. W. point is a lighthouse. The town is regularly built, has fine and well paved streets and squares, 3 gates, 3 Greek churches, 1 Anglican, 1 Lutheran, 1 Roman Catholic, and 2 Greek chapels. Other remarkable buildings are the exchange, custom house, arsenal, admiralty house, cannon foundery, barracks, and magazines; the marine hospital, with 3,000 beds; a house of Peter the Great, now the country residence of the military governor, whose garden still contains a few oaks planted by the hands of that czar; and a palace in the Italian style, erected by Mentchikoff, and now used as a naval school, containing 300 pupils for the navy, and 20 for merchant vessels. The last of these buildings is situated between the 2 canals of St. Peter and Catharine, which intersect the town. The former canal is constructed of granite, and is 2,160 feet long by 30 yards wide; it is in the form of a cross, and communicates by one of its arms with a vast dock, where 10 ships of the line can be repaired at once. The Catharine canal, 2¼ miles long, communicates with the merchant harbor, thus enabling the merchantmen to take their stores and provisions directly from the warehouses of the town. The quays, constructed by the emperor Nicholas, are all of granite, and on a grand scale. Except the government buildings, about 200 in number, all the older houses of the town are low, and mostly of wood. The harbor of Cronstadt, to the S. of the town, consists of 3 sections: the military, outer harbor, capable of containing 35 ships of the line, beside smaller vessels; the middle harbor, for the fitting out and repairing of vessels,

the hulls of new ones being brought over for equipment from St. Petersburg; and the innermost harbor, running parallel with the preceding, used only by merchantmen, and sufficient for 1,000 sail at a time. All these are well secured, but in consequence of the freshness of the water from the proximity of the mouth of the Neva, vessels cannot be preserved in them longer than 20 years. From November to the end of April they are blocked by ice. Notwithstanding the shortness of the shipping season, and the shallowness of the bay, which at the bar is only 9 feet deep, ⅔ of the foreign trade of Russia passes through this port. Entrances in 1856, 3,432 vessels, tonnage 547,951; clearances, 3,028 vessels, tonnage 469,812. In summer the surrounding sea is enlivened by steamers regularly running between Cronstadt and St. Petersburg, Helsingfors, Stockholm, Stettin, Lübeck, Havre, &c. Cronstadt was inundated in 1824, and blockaded in 1854 by the British fleet under Napier.

CRONSTADT, or KRONSTADT (Hung. *Brassó*), capital of a district of the same name, in the Austrian crownland of Transylvania. The district lies N. of the Carpathian mountains, an arm of which traverses it, and is watered by the Aluta and its tributary, the Burze, which gives it also the name of Burzenland. The soil is well cultivated, and produces all sorts of grain and pulse. It has gold, silver, and lead, and various mineral springs. The country abounds in game, fish, and bees, in horned cattle and pine timber. The population, about 100,000, is mainly composed of descendants of German settlers, of Wallachians, Hungarians, Greeks, and Armenians.—The town, pop. about 36,000, is beautifully situated in a narrow valley, enclosed by mountains. Charming villas on the slopes, with here and there an old castle on the heights, give a varied and picturesque aspect to the surrounding scenery. It consists of an inner town, which is surrounded by a wall and entered by 5 gates, and 3 suburbs, of which one, called the upper town or Bolgár, extends into the mountain passes, winds up the slopes, covering them with beautiful country mansions and well kept gardens and orchards, and is the favorite residence of the wealthy Wallachians. The 6 principal streets of the inner town are well paved and clean; the houses generally well built. It has a large market place, with 2 fountains, and at the main gate an esplanade covered with avenues of shady trees. The Protestant gymnasium, with a good library, the Roman Catholic high school, and the military hospital, deserve attention. There is a considerable trade in cattle, wine, corn, salt, and manufactured goods. The foundation of Cronstadt is traced back to the 13th century. In the 16th it was the starting point of the reformation in Transylvania, which was promoted by Honterus, a disciple of Melanchthon, who is said to have been in intimate correspondence with Luther, and to have also established the earliest printing press here (1533), its first productions being the Augsburg Confession and Luther's writings. Here, too, the first paper mill was erected. Cronstadt was formerly surrounded by strong fortifications, which are now in ruins. North-east of the town is a small citadel, situated on the summit of an isolated hill, which was not without importance in the Hungarian war of 1848–'49.

CROOKS, GEORGE R., D.D., an American clergyman and lexicographer, born in Philadelphia, Feb. 3, 1822. He was graduated at Dickinson college in 1840, and entered the ministry of the Methodist Episcopal church in 1841. His field of labor embraced portions of Fulton, Knox, and Peoria counties, in Illinois, his regular work being to preach 30 sermons every 4 weeks, beside having the pastoral oversight of a large territory. In 1842 he was elected classical and mathematical tutor in Dickinson college, and in 1843 he succeeded the Rev. L. Scott (now bishop) as principal of the grammar school of the college, and became associated with Professor McClintock in preparing "A First Book in Latin," and "A First Book in Greek," both of which have met with popular favor as text books. In 1846 he was elected adjunct professor of ancient languages, which position he held until 1848, when he resumed the pastoral office. He has had charge of prominent churches in Philadelphia, Wilmington, and New York, and as a preacher holds a place in the front rank of the profession. He has published an edition of Butler's "Analogy," containing a complete analysis of that work, with a new life of Bishop Butler, together with copious notes and an index. His last and most important work is a new Latin-English lexicon, adapted to schools and colleges, prepared in conjunction with Prof. Schem, of Dickinson college.

CROPSEY, JASPER FRANK, an American artist, born at Westfield, Richmond co., N. Y., Feb. 18, 1823. About the age of 14 he commenced the study of architecture, which, at the end of 5 years, he was obliged to relinquish on account of ill health. Having received a few lessons in water colors, he devoted himself thenceforth to landscape painting, and his third picture, a view of Greenwood lake in New Jersey, procured his election as an associate of the American academy of design, of which in 1850 he became a full member. In 1847 ill health compelled him to visit Europe, where he spent 3 years in close study of his art. Among his most successful productions after his return to America were the "Sibyl's Temple," and "American Harvesting," engraved by the American art union; "Peace" and "War," and "Niagara Falls." In June, 1856, he embarked for England, where he has since resided. Among his latest works are a series of American scenes, which are to be executed in chromo-lithography; several designs for illustrated books of poems; and compositions entitled "The Olden Time—A Tournament, and Return from Hawking." His subjects are chiefly landscapes, to which allegory and history are sometimes made accessory.

CROSLAND, Mrs. Newton, better known by her maiden name of Camilla Toulmin, an English authoress, born in London about 1817. Her father, a solicitor, died when she was a child, leaving the family mainly dependent upon the exertions of his son, who had also been trained to the law. Upon the death of the latter, Miss Toulmin, who had early manifested literary tastes and abilities, was forced to look to her pen for the means of support. She first appeared in print in 1838 as the authoress of a short poem in the "Book of Beauty," soon after which she became an active contributor to "Chambers's Magazine," the "People's Journal," and other periodicals, and edited for several years the "Ladies' Companion and Monthly Magazine." She has also published a volume of poems, "Lays and Legends illustrative of English Life," "Partners for Life, a Christmas Story," "Stratagems, a Tale for Young People," and a number of other works of fiction, designed to promote the moral and social culture of the people. She was one of the earliest to write for this end, and is regarded as a pioneer in the cause. In 1848 she was married to Mr. Newton Crosland, a merchant of London, in the environs of which she resides. She has recently become a convert to the doctrines of "Spiritualism," and has published a work illustrated with drawings by alleged spiritual agency.

CROSS (Lat. *crux*, Fr. *croix*), an ancient instrument of torture and death, commonly formed of two beams crossing each other. There were various forms of the cross: the *crux commissa* consisted of a transverse beam placed on the top of a perpendicular one, like our letter T; the *crux immissa* or *capitata* was a transverse beam crossing a perpendicular one at some distance from the top; and the *crux decussata*, or St. Andrew's cross, was made like the letter X. The Greek cross is a form of the *crux immissa*, the 2 beams crossing each other in the middle so that the 4 arms shall be of equal length. All these are varieties of the compound cross, beside which there was the simple cross consisting of a single stake on which the criminal was fastened or impaled. The shape of the cross on which our Saviour suffered is not known, for the historians who record its discovery give no description of it. It was probably the *crux immissa*, and such indeed is it commonly represented on ancient coins. A piece of wood bearing an inscription was placed on or above it, and there is reason to suppose that the feet of our Saviour were partly supported by a block placed beneath them, and to which they were nailed. Beside this, there was often a small resting place on which the body could slightly sustain itself as on a seat. The church early learned to regard the cross as an emblem no longer of disgrace but of victory. It became the favorite symbol of Christianity; it was fashioned in wood, stone, and metal; it was placed on tombs, altars, and religious structures, and sometimes on the front of private dwellings; and the faithful, not content with beholding its visible image, marked it with the hand on their persons. The sign of the cross was introduced into the ritual, and used in baptism, confirmation, and the Lord's supper. The Catholic church employs it in all sacred rites; it is the customary mode of benediction; it is many times repeated in the mass, and none of her sacraments can be rightfully administered without it. Roman Catholic bishops, abbots, and abbesses wear the cross suspended over the breast; and most of the priestly vestments display it embroidered in various forms. From the catacombs we have many curious examples of symbolical crosses, surrounded by other emblems, one of the commonest of which is a fish, denoting the water of baptism, or the "fishers of men;" or because the Greek word ιχθυς, a fish, comprises the initial letters of the Greek for "Jesus Christ, Son of God, Saviour." The dove, the serpent, A and Ω, were sometimes added to such representations, and often the cross was interwoven with the Greek letters X and P, the first two of the word Χριστος, or with a circle, the emblem of eternity. The latter is the sacred *tau* or *crux ansata*. The famous *labarum* or imperial standard of Constantine bore an image of the flaming cross which appeared to him in the heavens, and displayed the motto: Εν τουτῳ νικα, "By this conquer." From that time the sign of salvation glittered on the shields and banners of the Roman armies. Christian churches were soon built in the shape of a cross; and with the supposed discovery by the empress Helena, mother of Constantine, of the identical wood upon which Christ suffered, the veneration of the faithful took a new form. In 326 Helena, as related by Socrates, Sozomen, Rufinus, and Theodoret, visited the scenes of our Lord's sufferings. Every trace of the great events which had hallowed the environs of Jerusalem had been obliterated by the heathen, and a temple to Venus stood over Mount Calvary; but from a Jew who had treasured up what traditions he could gather, the empress learned the probable place of Christ's burial. The spot being excavated, 3 crosses were found, and the title which that of Jesus bore was discovered lying by itself. It is related that the cross of Christ was distinguished from the other two by miraculous cures wrought by touching it. A church was built over the spot; a part of the sacred relic was deposited in it; a part was sent to Rome and placed in the church of Santa Croce in Gerusalemme, built expressly to receive it; and the rest was inserted by Constantine in the head of a statue of himself at Constantinople. The first was carried away from Jerusalem by Chosroes, king of Persia, in 614, but was afterward recovered by the Roman emperor Heraclius, who restored it to its former place in 629. In the old chronicle of Geoffrey de Vinsauf, called the "Itinerary of Richard I.," we are told how the crusaders bore it with them to battle, how it was taken from them by Saladin at the battle of Hattin in 1187, and how the

pilgrims who went to the holy city in 1192 during the 3 years' truce were allowed "to see and kiss the true cross of our Lord." A piece of it is shown at Rome; another was preserved in Poland till the 17th century, when it was presented by John Casimir to the princess palatine, Anna Gonzaga, who bequeathed it to the monks of St. Germain in Paris; and innumerable minute fragments are held by Catholics throughout the world. A festival in honor of the finding or "invention" of the cross is still celebrated May 3, and the feast of the "exaltation of the cross," in commemoration of its restoration by Heraclius, is kept Sept. 14. The latter, however, according to some authorities, was instituted in the Greek church in honor of the appearance of the cross to Constantine. The ceremony of the "adoration (or more properly kissing) of the cross," which takes place in all Catholic churches on Good Friday, consists in presenting the feet of a crucifix to the lips of the people.—Architectural crosses were of several kinds, the principal being boundary, market, preaching, and memorial crosses. The first not only defined civil and ecclesiastical limits, but were sometimes endowed with the privilege of sanctuary. Market crosses were built partly to afford shelter in wet weather, and partly in token of the rights of neighboring monasteries to which belonged the tolls of the market. They are to be seen in many parts of England. At preaching crosses, sermons were delivered and proclamations were read. Memorial crosses marked the scenes of battles, murders, and other events, or in Alpine regions still denote the most dangerous parts of the mountain roads. Fifteen beautiful memorial crosses were built by Edward I. at the places where the body of his queen Eleanor rested during its removal from Grantham to Westminster. The processional cross, carried at the head of solemn processions, is often highly ornamented. There are many examples of the use of the cross as a sacred emblem among pagan nations, the earliest being found in Egypt and India. It is claimed that some have even been noticed in America.

CROSS, Joseph, D.D., a Methodist clergyman, born in Somersetshire, England, in 1813. He came to the United States at the age of 12, and entered upon the ministry in Genesee, N. Y., at the age of 16. He was for some time connected with the Transylvania university at Lexington, Ky., as professor of English literature, and has occupied some of the most important stations in the Methodist Episcopal church south. In 1855–'6 he travelled extensively in Europe, and wrote letters which were published extensively in the southern journals. He was a member of the general conference of the M. E. church south, which held its session in Nashville, Tenn., in 1856, and was the official reporter of that body. He has published "Pisgah Views of the Promised Inheritance," "Headlands of Faith," "A Year in Europe," "Life and Sermons of Christmas Evans, from the Welsh," and "Prelections on Charity." He is at present the principal of a female seminary at Spartanburg, S. C.

CROSSBILL, a bird belonging to the order *passeres*, tribe *conirostres*, family *fringillidæ*, and genus *loxia* (Linn.). The bill in this genus is moderate, broad at the base, with the culmen much curved, and the sides compressed to the very acute tip; the mandibles cross each other, having their lateral margins bent inward; the wings are moderate, the tail short and emarginated; the tarsi short, robust, and feathered below the knee; toes short, hind one with its claw very long, claws curved and sharp. These birds are found in the northern parts of both hemispheres, occurring in flocks in the forests of pines and firs, the seeds of which they eat; by means of the powerful bill and its peculiar construction, they pry asunder the scales of the cones; they also do much mischief in orchards by tearing open apples and pears in order to get the pips. The European species is the *L. curvirostra* (Linn.). The American crossbill is the *L. Americana* (Wils.). The length of the latter is 7 inches, and extent of wings 10 inches; the bill is brown, lighter on the edges, darker at the tip; iris hazel; general color a dull light red, inclining to vermilion, darker on the wings; quills and tail brownish black; the abdomen paler red, passing into whitish. The young males have tints of yellow and green, mixed with brown; in the female the upper parts are grayish brown, tinged with green, and the rump grayish yellow, as are also the lower parts. They are found in Maine and Canada even in midwinter, and on the shores of Lake Superior are seen in large flocks in the coldest weather, about the mining locations; they are also met with as far south as Pennsylvania. They fly quickly in an undulating manner, making considerable noise; they are easily domesticated, and in their wild state seem not to fear man. The eggs are 4 or 5, of a greenish white color, thickly covered, especially at the large end, with dark brown spots. The white-winged species (*L. leucoptera*, Gmel.) also inhabits the northern pine and spruce forests, the whole breadth of the continent, probably up to 68° N., where the woods terminate; it only resorts to temperate climates when forced by severe weather. The principal difference consists in the more slender bill, and in 2 white bands on the wings, formed by the secondary and first row of small coverts; the habits of the 2 species are the same. The singular form of the bill in this genus is a striking example of the adaptation of means to ends, which everywhere meets the student of natural history.

CROSSBOW. See Arbalast and Archery.

CROSSE, Andrew, an English electrician, born in Bromfield, Somersetshire, June 17, 1784, died July 6, 1855. He was matriculated at Brazenose college, Oxford, in 1802, but in 1805 returned to settle on his estate of Fyne Court, which he had some years previously inherited

from his father, and where he passed the greater part of his life. Having a strong predilection for the study of electricity, he provided himself with the necessary apparatus, and pursued his experiments without regard to theories. One of his first discoveries was the production of crystals by the effect of electricity. By the action of the voltaic battery, excited by water alone, upon a tumbler of water taken from a cavern in the neighborhood lined with aragonite crystallizations, he procured in a few days crystals of carbonate of lime. For 30 years he prosecuted these experiments, and succeeded in obtaining 41 mineral crystals, or minerals uncrystallized, in the form in which they are produced by nature, including one, subsulphate of copper, entirely new. He was of the opinion that it was possible to form diamonds in this way. As he worked alone and never published the results of his discoveries, they were unknown to the scientific world until the meeting of the British association for the advancement of science in Bristol in 1836, when he was induced to explain them publicly. The announcement excited unusual interest, and Mr. Crosse was publicly complimented by the president, the marquis of Northampton, and by Dr. Buckland, Dr. Dalton, Prof. Sedgwick, and other eminent scientific men. For many years previous he had been in the habit of employing the electrical fluid for ascertaining the state of the atmosphere and for other purposes, and had constructed a mile or more of insulated wire above the tree tops in the neighborhood of his house to aid his experiments. In 1816 he predicted, at a meeting of country gentlemen, "that by means of electrical agency we shall be able to communicate our thoughts instantaneously with the uttermost ends of the earth," although it does not appear that he ever attempted to fulfil his prediction. The discovery, however, with which his name is chiefly connected, is that of the apparent production of insects by the action of the voltaic battery upon certain chemical fluids. In 1836, while pursuing his experiments in crystallization with a highly caustic solution, out of contact with atmospheric air, he noticed the appearance of an insect of the acarus tribe, of which upward of 100 more were formed within a few weeks. The discovery caused a considerable sensation, and although Mr. Faraday and Mr. Weeks of Sandwich amply confirmed the statements of Mr. Crosse by their own experience, the latter was accused of the impiety of assuming to become a creator. Crosse, who was a man of sincere religious convictions, was much affected by these imputations, although he could give no explanation of the manner in which the insects were produced. In answer to a person who had attacked him with unusual virulence, he said that he was sorry if the faith of his neighbors depended upon the claw of a mite. Recent experiments on the same subject by Prof. Schulze of Germany failed to obtain the appearance of insects or animal germs, thus confirming the probability which Mr. Crosse never disputed that the ova of the insects were derived from the atmosphere, or conveyed into the apparatus by some natural means unknown to the experimenter. Among the practical benefits of his experiments was the discovery of a process for purifying salt water by means of electricity. He also made some curious discoveries with reference to the effects of positive and negative electricity upon vegetation. He was a benevolent man, an active magistrate, and a useful friend to the poor. A memoir, including many original poems written by him, was published after his death by his widow.

CROSWELL, Edwin, an American journalist and politician, nephew of the succeeding, born in the village of Catskill, N. Y., about 1795. Upon the completion of his education, he became an assistant editor of the "Catskill Recorder," a journal established in Catskill in 1790 by his father and uncles. The first article which he wrote for the press was a vindication of the drafted soldiery of the state who had been called out for the defence of New York, in the last war with Great Britain. His political affinities were with the party who advocated the war, and after the retirement of his father, his management of the paper was such as to attract the attention of public men prominent in the political history of the state. In 1823–'4, upon the death of Judge Cantine, printer to the state and editor of the "Albany Argus," he was invited by Mr. Martin Van Buren, Mr. Benjamin F. Butler, and others, to assume the control of that paper. Thenceforward he became a resident of Albany, and was closely identified with the growth and prosperity of the "Argus," and with some of the most important political movements of the time. He converted the "Argus" from a semi-weekly into a daily journal, increased its circulation very largely, and made it one of the chief organs of the democratic party, not merely in the state, but in the country. The organization of the party was at that time as perfect as political sagacity could make it, and to Mr. Croswell, as a member of the so-called "Albany regency," a group of politicians who directed the councils of the party in the state of New York, was assigned the delicate task of composing, through the columns of the "Argus," all intestine difficulties, and preserving order in the ranks. To the tact with which he discharged this duty has been ascribed, in no inconsiderable degree, the ascendency which the democratic party long maintained in the state. The minor party presses habitually copied the leading articles of the "Argus," as the embodiment of the soundest democratic principles; and so potent was the influence of Mr. Croswell's name and of his paper, that for many years to discredit the authority of the "Argus" was equivalent to a renunciation of party ties. In 1840, Mr. Croswell was succeeded as state printer, a position he had held for the previous 17 years, by Mr. Thurlow Weed, editor of the "Albany

Evening Journal." In 1844 Mr. Croswell was reinstated for a period of 3 years. Various changes had meanwhile affected the harmonious action of the party which he had so long promoted, and he found himself opposed to some of his earliest political associates, among others to Mr. Van Buren. The "Argus," however, continued to be one of the principal organs of the democratic party, and Mr. Croswell invariably supported its candidates for national offices. In the more difficult matter of state politics, his influence has necessarily been of less weight than formerly. In 1854 he retired from the "Argus" and from all connection with the newspaper press, after an eventful editorial life of about 40 years. His pen has occasionally been employed on addresses and other literary productions not of a professional character, and he is said to be preparing for publication his personal reminiscences of the men and events of his time.

CROSWELL, Harry, D. D., an American journalist and clergyman, born at West Hartford, Conn., June 16, 1778, died at New Haven, March 13, 1858. He was first publicly known as the editor of the "Balance," a journal founded by him in 1802 at Hudson, N. Y., in which he was associated with Ezra Sampson, by education a Presbyterian clergyman. Mr. Croswell, who was a federalist, wrote in the then prevailing spirit of bitterness, and became involved in many libel suits and prosecutions, celebrated at the time. In one of these, for an article on Jefferson, published in the "Wasp," a journal under his direction, Alexander Hamilton made his last forensic effort in his defence. Mr. Croswell afterward removed to Albany, and established a federal paper; but turning his attention to theology, he retired from journalism and took orders in the Episcopal church in 1814. He became rector of Trinity church, in New Haven, Feb. 22, 1816, and was in the latter part of his life almost as remarkable for the dignity and gravity of his deportment as he had been in his earlier career for its impetuosity. He was the author of several devotional works, and a memoir of his son, the Rev. William Croswell, D. D.—William, D. D., son of the preceding, born at Hudson, N. Y., Nov. 7, 1804, died in Boston, Nov. 9, 1851. He was graduated at Yale college in 1822, and took orders in the Protestant Episcopal church in 1828. In 1829 he became rector of Christ church, Boston, in 1840 of St. Peter's, at Auburn, N. Y., and in 1844 returned to Boston to assume the charge of the church of the Advent, whose services he directed in conformity with the ancient rubrics rather than the practice of other churches or the sentiments of his ecclesiastical superiors. His views in regard to the external arrangements of the church led to a controversy with Bishop Eastburn, by whom he was officially censured; but his church prospered none the less, for the life of the pastor was a beautiful example of self-denying charity and religious devotion. He became suddenly ill while conducting divine service in his church on Sunday afternoon, and lived but a short time after being removed to his residence. His poems are mostly short lyrical pieces, in commemoration of the observances and memorial seasons of the church to which he was devoted.

CROTCH, William, an English composer, born at Norwich in 1775, died at Taunton, Dec. 29, 1847. When scarcely 2 years of age he could play tunes on the harpsichord, and a year later was able to add a bass. This precocity attracted the attention of Dr. Burney and other distinguished musicians, but the expectations excited by it were never fulfilled. Crotch became an accomplished musician, but his compositions, of which he published a great number, have no special merit. He was made a doctor of music by the university of Oxford, in which he also filled the chair of professor of music.

CROTON, a river of the state of New York, flowing through Dutchess, Putnam, and Westchester counties, and entering the Hudson river about 35 m. above New York city. From this stream the city of New York is supplied with water through the Croton aqueduct; for a description of which, see Aqueduct.

CROTON OIL is expressed from the seeds of the *croton tiglium*, a native of Ceylon, Molucca, Hindostan, and of other parts of Asia. These seeds are rather larger than a common pea, of an ovate form, and of a brownish color. The kernels contain about 50 per cent. of oil, which is of a pale yellow color. It has a slight odor, and a bitter, burning taste. It is a speedy and powerful purgative, and acts with good effect upon the patient when taken in small doses. Taken in large quantities, it produces vomiting and great pain, and is sometimes fatal in its effects. It has been long used in India, and was known in Europe as early as 1630, but attracted little notice. It was introduced into England in 1820, but does not yet receive the attention which it deserves. In cases of constipation, where all other medicines fail, it has proved highly beneficial. It is also employed in dropsy, apoplexy, and in almost all diseases in which the patient has a tendency to torpor. Externally applied, it is found advantageous in cases of gout, rheumatism, neuralgia, glandular swellings, and in pulmonary complaints. Thus applied, it produces inflammation of the skin, with pustular eruptions. The oil is sometimes incorporated with the lead plaster, melting at a gentle heat 3 parts of the latter with 1 of oil. Much of the croton oil imported to this country is not genuine, being procured from plants different from the *C. tiglium*.

CROTONA, or Croton, an ancient Greek colony in southern Italy. The city stood near the mouth of the river Æsarus, on the E. coast of the Bruttian peninsula. It was founded by a body of Achæans and Spartans, probably about 710 B. C., and soon became distin-

guished for size, wealth, and power. According to Livy, its walls enclosed a space 12 m. in circumference. In the war with Sybaris, 510 B. C., Crotona is said to have sent into the field 100,000 men, and to have conquered the Sybarites with a force of 300,000. Some time afterward the Crotonites were themselves defeated by the Locrians near the river Sagras, and never again recovered their national importance. In the 2d Punic war they were no longer able to defend their own walls, and a few years later a Roman colony was sent out to recruit the exhausted population of the city. Crotona was celebrated in ancient times for the school of Pythagoras.

CROUP (*cynanche trachealis*, *angina membranacea*, and *diphtheritis trachealis*, of authors), an acute inflammation of the mucous membrane of the larynx, trachea, and bronchial tubes, characterized by the production of false membranes on their internal surface. There is a spasmodic affection of the larynx (*laryngismus stridulus*), sometimes erroneously called croup, but which is entirely different in its nature, symptoms, gravity, and treatment. Croup is sometimes preceded by the symptoms of a common cold, with hoarseness and a harsh cough, pain in the head, fever, and especially by swelling and redness in the back of the throat; but it may come on suddenly during the night, and in the midst of apparent health. The first symptom observed may be the peculiar ringing, brazen cough, occurring most likely in the night; then the voice becomes sharp, the respiration noisy and difficult, and accompanied by a crowing sound during inspiration; the face is red and swollen, the eyes suffused, the skin hot, the pulse hard and quick; the head is thrown back, and every thing indicates the distress of the sufferer; the occasional cough brings up nothing but some thick mucus, tinged perhaps with blood. A treacherous calm may succeed this agitation, and the patient may fall asleep; but a new paroxysm will soon reawaken him, more severe than the first unless the disease be cut short by appropriate remedies. In the intervals the child may seem well, except from a hoarseness of the voice and a slightly noisy respiration. As the disease advances, the breathing becomes more difficult, the cough more suffocating, the voice stifled, and the countenance livid; the extremities become cold, and coma or convulsions close the scene. Notwithstanding the difficulty of breathing, swallowing is generally easy; false membranes of greater or less exent are occasionally coughed up with a partial, or, in rare cases, complete relief. The disease may run to a fatal termination in a few hours, or it may continue many days, ending in death or recovery. According to Bretonneau, croup is only an extension of a diphtheritic inflammation from the pharynx to the air passages; indeed, perhaps in the majority of cases the false membrane may be seen upon the tonsils and posterior fauces before the larynx is affected; and it is often the good fortune of the physician to arrest this fearful disease, when this early indication of danger is understood and attended to. The brazen respiratory sound is heard chiefly during inspiration; and when false membranes have formed in the larynx there is generally a prolongation of the expiration. The dyspnœa occurs usually at night, and during sleep; its suffocative symptoms, change in the features, dilatation of the nostrils, and agitation of all the respiratory movements, are found in no other disease. Auscultation detects nothing characteristic in the lungs, except diminution or absence of the respiratory murmur in proportion to the obstruction in the larynx; all râles, except those caused by the flapping of membranes which have extended into the bronchi, must be the result of complications not belonging to pure croup. The disease may be said to be peculiar to childhood, between the 1st and 10th years, though older children, and even adults, are occasionally affected; it is most common in cold, damp seasons, and those characterized by sudden changes, and in low, marshy localities; it prevails sometimes epidemically and endemically, but is never contagious; it often occurs soon after the eruptive fevers, whooping cough, and catarrhal diseases, especially during epidemics; there seems to be a predisposition to it in certain families, and those who have been once attacked are liable to other seizures. The pathological characters are redness and swelling of the mucous membrane of the air passages, and the presence of a membranous concretion of various extent and consistence, though death may occur from the violence of the inflammation and its extension to the lungs before the formation of the latter. Croup is a very dangerous disease; leaving out of the case the many affections which have been erroneously called croup, it may be stated that the mortality is certainly 66 per cent. in well defined cases, and probably considerably greater than that under the old forms of treatment. At the present time bleeding is very rarely resorted to, unless locally by leeches; emetics can hardly be recommended as general practice, except for the dislodgment of false membranes evidently loose; mercurials, both internally and by the skin, have always been regarded with favor in this country, but are of questionable utility in most cases, and positively injurious in many; the prostration following the fractional exhibition of antimonials has not been found to arrest the disease; purgatives, expectorants, blisters, tonics, and antispasmodics have been freely used to little purpose. There is probably no better general treatment than the following, recommended by Prof. John Ware: 1, to avoid all reducing, depleting, and disturbing measures, as bleeding, emetics, purgatives, and blisters; 2, to keep the patient under the full influence of opium, combined perhaps with calomel; 3, constant external application of warmth and

moisture, and of a slightly stimulating mercurial liniment; 4, sponging with warm water, and poultices of flax seed or mullein leaves to the throat; 5, the inhalation of watery vapor. A great improvement on the use of acid gargles, alum and calomel insufflations, and acid caustics, is the now prevalent application of nitrate of silver. The fibrinous exudation is a secretion from the muciparous glands of the mucous membrane, irritated by some unknown specific cause; as this exudation almost always begins in the upper portion of the air passages, and progresses downward, it may often be checked by the application of a strong solution of nitrate of silver to the tonsils and opening of the glottis; in an hour or less the operation may be repeated, and the caustic applied within the glottis; this will generally be followed by vomiting and the discharge of any existing membrane; the caustic and the emesis will, if any thing can, arrest the exudative inflammation. After this first and most important step, the treatment of Dr. Ware can hardly be improved; in the later stages, when complicated with bronchitis, prussic acid is the best remedy for the distressing spasmodic cough. In desperate cases, tracheotomy has been performed with immediate relief and ultimate recovery; of course it would be useless when the false membranes had reached the bronchi. All remedies, however, to be effectual, must be applied very early in the disease.—*Laryngismus stridulus*, or spasmodic croup, as it is sometimes called, occurs during the first 2 or 3 years of life, from the irritation of dentition, deranged digestion, or insufficient nutrition; the spasm sometimes extends to the muscles of the extremities. The inspiration is crowing, not followed by cough. It seems to be essentially a spasm of the glottis, not immediately dangerous, and is to be treated by tonics, alteratives, attention to the general health, and the removal of any obvious causes of irritation in the dental or digestive systems. Recovery is general; and many of the far-spread remarkable cures of croup are nothing more than cases of this spasmodic or croup-like disease, which may even cease without treatment.

CROUSAZ, Jean Pierre de, a Swiss philosopher and mathematician, born at Lausanne, April 13, 1663, died March 22, 1748, studied at Geneva, Leyden, and Paris, and was ordained pastor of a church at Lausanne. In 1699 he was appointed professor of Greek and philosophy in his native city; in 1724, professor of mathematics and philosophy in Groningen; and in 1737, professor of the same in Lausanne. Beside his sermons, he published many works upon logic, education, and philosophy, and also upon higher geometry.

CROW (*corvus*), a genus of birds belonging to the order *passeres*, tribe *conirostres*, and family *corvidæ*. More than 20 species are described, found in most parts of the globe; some remain stationary within a certain district, while others migrate from place to place with the changes of the seasons; they generally assemble in flocks in cultivated places, in search of worms, grubs, caterpillars, small animals, the eggs and young of birds, carrion, and various grains and cultivated vegetables; a few species frequent the sea shore, to feed upon the dead fish cast up by the waves, or in quest of shell-fish, which they break by letting them fall from a considerable height upon the rocks. The genus *corvus* includes the raven, the rook, the jackdaw, and other species not usually denominated crows, which will be noticed under their proper heads. Four species only will be described here, viz.: the American, the European, the hooded, and the fish crow. I. The American crow (*C. Americanus*, Audubon) was first separated from the European species by Audubon, and there can be but little doubt that they are distinct. The bill of the adult is $2\frac{1}{6}$ inches along the ridge, of a black color, straight, strong, and compressed; the upper mandible a little convex, the lower mandible straight; the edges of both sharp and inflected. The nostrils are basal, lateral, round, and covered by bristly feathers directed forward. The head is large, and the whole form of the bird compact and graceful; the legs are strong and of moderate length; the tarsi are $2\frac{1}{2}$ inches long, black, and covered with scales anteriorly; the toes and claws are black, the latter being moderate, arched, compressed, and sharp; the 3d toe is the longest, the other 3 being nearly equal. The plumage is of a general deep black color, with purplish blue reflections, and tinged with purplish brown on the back of the neck; the under parts are less glossy, and the feathers are less compact than those of the back; the plumage of the head and neck is well blended; the wings are long, the 1st primary short, and the 4th the longest, the primaries are tapering, and the secondaries broad; the tail is long, rounded, of 12 feathers with their shafts undulated. The length of this crow is 18 inches, and the extent of wings 3 feet 2 inches. The iris is of a brown color. The female is slightly less glossy than the male, and the young are of a dull brownish black, with less brilliant reflections. There is probably no bird more generally and unjustly persecuted than the crow; every farmer thinks himself privileged to destroy it, and counts the death of every one as a gain to agriculture. Of course the bird, in order to save his race from extermination, must employ all his cunning and ingenuity to avoid his enemies; hence his extreme shyness, and certain flight at the sight of any one armed with a gun, the destructive properties of which he seems well acquainted with; perched on a high tree, he sounds the alarm at the approach of danger, and all the crows within half a mile fly off at the well-known cry of the watchman. Thousands of crows are destroyed every year by guns, traps, and poisoned grain; and multitudes of the young birds are killed in their nests by every urchin who can climb a tree.

Though the crow pulls up a few seeds of the germinating corn, his services to the agriculturist far outweigh his depredations; he daily devours insects, grubs, and worms, which but for him would devastate whole fields of the young corn; he destroys innumerable mice, moles, and other small quadrupeds, every one of which commits 10 times the mischief he does; he will eat snakes, frogs, lizards, and other small reptiles, and also fruits, seeds, and vegetables, and, if hard pressed for food, will even descend to carrion. He will steal and devour the eggs of other birds, and will occasionally prey upon a weak or wounded bird; he delights to worry the owl, the opossum, and the raccoon, and will pursue the thievish hawk, and even the eagle with all the forces that he can raise in the neighborhood; he is said to follow the larger carnivora, probably to partake of the bits which they may leave. On the whole, the crow is a persecuted, comparatively harmless, and indeed a most serviceable bird, and deserves better treatment from the American farmer. Audubon says to the farmers: "I would tell them that if they persist in killing crows, the best season for doing so is when their corn begins to ripen." Wherever the crow is abundant the raven is scarce, and *vice versa*. The crow is common to all parts of the United States, assembling, after the breeding season, in large flocks, many of which remove to the southern states in the winter. It builds its nest in thick swamps, or on the sides of steep rocks, as much concealed as possible; the period of breeding varies from February to June, according to latitude. The nest is made of sticks interwoven with grasses, plastered within with mud, and lined with soft roots, feathers, or wool; the eggs are from 4 to 6, of a pale greenish color, spotted and clouded with brownish green and purplish gray; both sexes sit upon the eggs, and watch over their young with the tenderest care; in the southern states they raise 2 broods in a season. Several nests are often found near each other, and when any stranger approaches the community, the noise of the assembled multitude is almost deafening until the intruder retires. The young, when just about to leave the nest, are considered in some localities tolerable food. The flight of the crow is swift, capable of being sustained a long time, and sometimes at a great height; on the ground its gait is graceful and slow; it often alights on the back of cattle, to pick out the worms from the skin. Their well-known notes, "caw, caw, caw," are very discordant, especially in early morning when they scatter into small flocks in search of food, and toward evening when the returning parties are selecting their roosting places for the night. The crow is very courageous against its bird enemies, and will not hesitate to attack any marauding hawk which comes within its range. It makes a very interesting pet, as it displays considerable intelligence and docility; but its propensities are decidedly thievish. Like many other birds of a black color, the crow is occasionally perfectly white. The sight of the crow is very keen; and it is by this sense, and not by the sense of smell, that this bird is guided in its search of food, and in the avoidance of its human enemies. When on its marauding excursions after eggs, which it carries away on the bill, it is often attacked and driven away, especially by the courageous king-bird. II. The European, or carrion crow (*C. corone*, Linn.), is larger than the preceding species, being from 20 to 22 inches long, with an extent of wing of 40 inches; the bill is stronger, deeper, more convex on the sides, and the edges more inflected; the feet and toes are larger and stronger, and the claws robust in proportion. Were it not for its smaller size and some differences in the form of the feathers, it might be confounded with the raven, as its proportions are about the same, the body being full and ovate, and the neck short and strong. The palate is flat and the tongue oblong, while in the American species the palate is concave and the tongue is narrower. The plumage is moderately full, compact, and very glossy; the feathers of the hind neck are narrow and with their points distinct, but in the American bird they are broad, rounded, and so blended that the form of each is not easily traced; the feathers of the fore neck are lanceolate and compact at the end, as in the raven, but in the American crow they are three times as broad, rounded, and entirely blended; in other respects the plumage is alike in the two birds, the neck of the former being tinged with green and blue, but in the latter with a distinct purplish brown. From this description it can hardly be doubted that the American and European crow are distinct species. The female is similar to the male in color, but somewhat smaller; the tints of the young have less of the metallic lustre. The carrion crow preys upon small quadrupeds, young hares and rabbits, young birds, eggs, crustacea, mollusks, worms, grubs, and grains; but, as its name imports, its favorite food is carrion of all kinds; it often destroys young lambs and sickly sheep; it is very fond of attacking parturient ewes, frequently killing both the mother and the young, tearing out the eyes, tongue, and entrails, in the manner of the vultures; whatever its food may be, it is exceedingly voracious. Unlike the American species, the carrion crow does not associate in large flocks, but is generally solitary or in pairs, except in breeding time, when a whole family will remain together for some weeks. Its flight is sedate and direct (hence the expression, "as the crow flies," for a straight line), and performed by regular flaps of the fully extended wings; it does not soar to any great height, and prefers the open moors, fields, and shores to mountainous districts. Its gait is similar to that of the raven, and its cry is a croak quite different from the bark-like cawing of the American crow. It builds its nest, of large size, amid

high rocks, or on tall trees, and lays from 4 to 6 eggs of a pale bluish green color, spotted and blotched with dark brown and purplish gray; these colors, however, vary considerably; the eggs are about 1¾ inches long, and 1⅛ inches in their greatest width. They not unfrequently build in the neighborhood of farm houses, in order to be near any rejected offal, and watch their opportunity to pounce upon chickens or ducklings, and to steal eggs from any of the domestic fowls. The carrion crow is very easily tamed, and is capable of strong attachment; its docility is great, and its memory astonishing; its propensities are thievish; like the raven and the jackdaw, the carrion crow may be taught to imitate the human voice. According to Temminck, this species occurs over all western Europe, but is rare in the eastern parts. III. The hooded crow (*C. cornix*, Linn.) has the head, fore neck, wings, and tail of a black color, with purplish blue and green reflections; the rest of the plumage is ash-gray tinged with purplish, the shafts being darker; the female is similar to the male, somewhat smaller, the black on the fore neck less in extent, and the gray of the back less pure; the plumage of the young is black, with the exception of a broad band of dusky gray round the fore part of the body. This species, with the exception of the color, much resembles the carrion crow; it is somewhat smaller, the length being about 20 inches, and the extent of wings 39 inches. It is abundant in the northern parts of Scotland, and it occurs in all parts of Europe; it prefers the coast, and the neighborhood of large maritime towns. It is not gregarious, not more than 5 individuals being often seen together; it is quite as omnivorous as the preceding species, though it prefers fish and mollusks to the carcasses of larger animals; it has sagacity enough, when it cannot open crabs and shell-fish, to raise them into the air and drop them on the ground for the purpose of breaking them. It is very fond of perching upon a stone or tree in dull weather, and croaking for a long time, being answered by others who have stationed themselves at a distance; this habit has been considered by the common people as indicative of rain. Its ordinary flight is slow and regular, and its gait upon the ground remarkably sedate and dignified. It is a peaceable bird, rarely attacked by, and rarely attacking others. It does not soar, nor skim the hillsides in search of food, but skulks along the low grounds in the vicinity of water; it destroys many of the eggs and young of the plover and the red grouse and other birds frequenting the moors. They remain paired the greater part of the year, and almost always construct their nest on a rock near the sea; the eggs, usually 5 in number, are of a pale bluish green tint, marked, especially at the large end, with roundish spots of greenish brown and pale purplish gray. The hooded crow is generally found in different localities from the carrion crow; and, when existing in the same district, the species keep separate, the latter being much more shy and wild. It is said, and probably with truth, that the species breed together, producing hybrids intermediate between the two; it must be difficult to distinguish such hybrids from the present species, as the space occupied by the ash-gray varies greatly in different individuals. IV. The fish crow (*C. ossifragus*, Wils.) is smaller than the common crow, having a length of only 16 inches and an extent of wings of 33 inches; the bill is nearly 2 inches, and the tarsus 1¾ inches long. These two birds resemble each other in general appearance; the bill in the fish crow is concave on the sides at the base, and flat in the middle; the plumage in its general color is deep black, with blue and purple reflections above, and blue and greenish beneath; the bill, tarsi, toes, and claws are black; the iris dark brown. This species is abundant in the southern states, in maritime districts, at all seasons; it is occasionally seen as far north as New York in spring and summer, returning to the south in winter. The fish crow is not persecuted like the common species, and is therefore quite familiar in its habits, approaching houses and gardens without fear, and feeding unmolested on the best fruits. Its favorite food, as its popular name implies, is fish; at early dawn the flock takes wing for the sea-shore, in a very noisy manner; they skim along the shallows, flats, and marshes in search of small fish, which they catch alive in their claws, retiring to a tree or stone to devour them. Like others of the genus, this species will feed on all kinds of garbage, on crabs and mollusks, on eggs and young birds, on the berries of various kinds of *ilex* and *stillingia*, on mulberries, figs, whortleberries, pears, and other ripe fruits; they are in the habit of attacking on the wing the smaller gulls and terns, and of forcing them to give up their recently caught fish. They breed in February and March in Florida and South Carolina, and a month later in New Jersey; the nests are usually made in the loblolly pine, on the ends of the branches about 30 feet from the ground; the nest and eggs resemble those of the common crow, but are smaller. The note is different from that of the other species, resembling, according to Audubon, the syllables *ha*, *ha*, *hae*, frequently repeated; at night they are still, in the morning very noisy, and in the breeding season not disagreeable nor monotonous. Their flight is strong and protracted; they generally fly near the water, but occasionally they rise to a great height. On the ground their movements are graceful; and they are fond of opening and shutting their wings, a habit common to the other crows. They can disgorge their food like the vultures, when wounded and attempting to escape; they are easily approached and shot, and in winter, when their food is chiefly fruit, they are very fat, and considered good eating. The female is smaller, and the gloss on the plumage is less bright, with brown reflections on the upper parts; the length is 15

inches, and the extent of wings 31 inches.—The habits of the crows seem to be the same in all countries. The carrion crow of Ceylon detects the wounded deer, and discloses its retreat to the hunter by congregating on the neighboring trees. Whenever this bird sees an animal lying on the ground, it soon collects all its comrades in the vicinity; one of the boldest hops upon the animal's body; as this is not uncommon in their search for ticks, the creature lies still, grateful for the expected riddance of the vermin. Finally the crow looks into the eyes; then the animal, if able to defend itself, removes the dangerous friend by a shake of the head; but if the eyes be dim from disease or wounds, full well the crow knows it, and plunges its powerful bill into the eyeball of the struggling sufferer, and feasts upon its favorite morsel; the rest soon join, and attack the parts giving easiest access to the entrails. The hooded crow of Ceylon, like the other mentioned in Layard's "Ornithology of Ceylon," lives amid the densest populations, stealing every thing eatable that comes in his way; if the spread table be left for a moment, the marks of feet upon the cloth, of bills in the butter, and the disappearance of small bits, show that the robbers could not have been far off; indeed the sable watchmen sit perched on rafter and roof, with inclined heads, ready for every opportunity to attack the box of rice or the store of dried fish. They are useful scavengers, and are rarely molested by the natives, of whom they stand in no fear; but at the appearance of the white man with his gun, the whole corvine community is in an uproar, and flies hurriedly to a safe distance till the danger is over.

CROWE, Catharine (Stevens), a living English authoress, born at Borough Green, in the county of Kent, married in 1822 Lieut. Col. Crowe of the royal army, and began her literary career in 1838 by the publication of a tragedy entitled "Aristodemus." Adopting a more popular style of composition, she soon after published a novel called "Manorial Rights," which was succeeded by the "Adventures of Susan Hopley." The latter was marked especially by a rapid succession of various incidents, and was reproduced in a dramatic form. Her 3d novel, "Lilly Dawson," appeared in 1847, and was designed to show the influence of the affections upon the development of the intellect. In 1848 she translated from the German of Kerner the "Seeress of Prevorst;" and being thus introduced to the study of the phenomena of animal magnetism, she has since published several tales, some of them of a fantastic character, containing incidents and observations with reference to the supernatural world and to dark points of experience. The "Night Side of Nature" (1848) was a skilful effort to awaken an interest in the whole doctrine of spirits. Among her later publications are "Pippie's Warning," "Light and Darkness, or the Mysteries of Life," the "Adventures of a Beauty," and "Linny Lockwood."

CROWN (Lat. *corona*), a wreath-shaped or circular covering for the head, made either of leaves and flowers or of metals and precious stones, and worn as a decoration or honorable distinction. The legends of the Greeks attributed its invention to Prometheus or Janus, and the earliest Greek crowns were worn chiefly on festive occasions, and were twined of twigs of the tree or plant sacred to the divinity who presided over the festival. They rarely contained more than a single kind of leaves or flowers, as the ivy, myrtle, roses, violets, and lilies. The ivy was in especial esteem on Bacchanalian occasions, since it was believed to be a preventive of drunkenness. Circular garlands were common ornaments also for priests, altars, temples, graves, and sacrificial offerings. At the national games, a crown was the reward granted to the victors. It was made of wild olive for the Olympic heroes; of laurel, for the Pythian; of olive, and afterward parsley, for the Nemean; and of pine, for the Isthmian.—The Romans gave crowns to the conquerors in the circus, and to the best actor at the theatre. They also invented a great variety of crowns, made of different materials, each with a separate name, which were bestowed in honor especially of military achievements. The *corona obsidionalis* was presented by besieged cities or armies to the general who delivered them; it conferred the highest honor, was rarely obtained, and was made of weeds and wild flowers gathered from the spot where the troops or citizens had been beleaguered. The *corona civica* was the reward for a soldier who should save the life of a citizen in battle, by slaying his opponent and maintaining the ground; it was an oak wreath, and was the second of the military crowns in honor. The *corona rostrata* or *navalis* was bestowed upon the Roman who in a naval combat had first boarded the enemy's vessel, or the commander whose skill and courage had gained a signal victory; it was of gold, and decorated with representations of the beaks of ships. The *corona muralis* was given by the general to the soldier who first scaled the wall of a besieged town; it was of gold, and decorated with turrets. The *corona castrensis* was ornamented with palisades, and was given to the soldier who first surmounted the intrenchments and forced an entrance into the enemy's camp. The *corona triumphalis* was a wreath of laurel (afterward of gold), given by the soldiers to the victorious general on the day of his triumph. The *corona ovalis*, of myrtle, and of less estimation than the preceding, was given to generals who enjoyed an ovation instead of a triumph. The *corona oleagina* was a wreath of olive, and was bestowed upon victorious soldiers as well as generals. There was also a crown of olive or gold peculiar to the priests, which was also regarded as an emblem of peace; radiate crowns attributed to gods and deified heroes and emperors; and a crown of verbena, worn by brides, by whom it was gathered and braided. The custom of crowning poets with wreaths of flowers existed both

among the Greeks and Romans.—The crown under different names, as crown, tiara, mitre, and diadem, has been a badge of civil and ecclesiastical supremacy from remote antiquity. The mitre of the Jewish high priest and the radiate crowns upon coins of ancient Persian kings are examples. The Roman and Byzantine emperors wore crowns of various kinds, the diadem, a sort of fillet, becoming common after the time of Constantine. The imperial crown of Charlemagne, imitated from Byzantine usage, was closed above like a cap, and terminated in a circle of gold. During the middle ages the emperors of Germany received 3 crowns: that of Germany, which was of silver, and was assumed at Aix la Chapelle; the crown of iron, which had formerly been peculiar to the Lombard kings, and was assumed at Pavia; and the imperial crown, which was received at Rome, and was surmounted by a mitre similar to that of bishops, but somewhat smaller. The crown of iron, though chiefly of gold, derived its name from an iron band which encircled it in the interior, and which was said to have been made from one of the nails which served in the crucifixion of Christ. It is still preserved in the cathedral of Monza, and is one of the crowns of the Austrian emperors, who are now masters of the Lombardo-Venetian kingdom. Napoleon wore it when he was crowned king of Italy at Milan. The kings of France of the 1st race wore a diadem of pearls in the form of a fillet; those of the 2d wore a double row of pearls; those of the 3d wore a circular band of gold enriched with precious stones. Philip of Valois introduced the 3 fleurs de lis about 1330. Francis I. returned to the crown of Charlemagne, arched over the head, in order not to leave this mark of superiority to Henry VIII. and Charles V.; and from that time this has continued to be the crown of France.—A fillet of pearls appears from coins to have been the most common crown of the Saxon kings of England. Stephen introduced the open crown with fleurs de lis, and Richard III. first placed the arched crown with crosses and fleurs de lis upon the great seal. The crown which, with slight variations, has been continued by succeeding sovereigns, was introduced by Henry VII. At present it is a circle of gold, adorned with pearls and precious stones, having alternately 4 crosses patée and 4 fleurs de lis; above these rise 4 arched diadems, which close under a mound and cross. The whole covers a velvet cap trimmed with ermine.—About the 10th century, when the feudal lords disputed the royal supremacy, all the ranks of the nobility assumed a sort of crown. (See Coronet.)—The popes have for many centuries worn a triple crown, which is designed to signify their ecclesiastical, civil, and judicial supremacy. It consists of a long cap or tiara of golden cloth, encircled by 3 coronets, one rising above the other, surmounted by a mound and cross of gold.

CROWN POINT, a township of Essex co., N. Y., on the W. shore of Lake Champlain, about 75 miles N. of Albany, and noted as the site of a famous fort, now in ruins.

CROYDON, a market town and parish of England, co. of Surrey, on the river Wandle, near Banstead downs, 10 m. S. of London, with which it communicates by the London and Brighton railway. A branch line also connects it with Epsom. Pop. of the town in 1851, 10,260. The houses are mostly well built, and the streets, the principal one of which is a mile long, are paved and lighted with gas. It has an elegant and capacious church of freestone, built in the 15th century, 2 modern churches, several chapels and schools, a hospital, an alms house richly endowed for the maintenance of 34 decayed housekeepers, a literary and scientific institution, a handsome town hall, a barrack, a gaol, breweries, bleacheries, and calico print works. The manor of Croydon (called in the Domesday book Cruie-dune, chalk hill), together with a royal palace, was given at the Norman conquest to Lanfranc, archbishop of Canterbury, whose successors resided here for a long time. The palace has been gradually rebuilt since 1278, at which period it was in its original state, and the oldest portion now left is of the 14th century. In 1780 it was converted into a calico factory, which has since been abandoned. A girls' industrial school is taught in the old chapel. The manufactures of Croydon have been declining for several years.

CROYLAND, or Crowland, a town of Lincolnshire, England, at the confluence of the Welland with 2 smaller streams, 8 m. N. of Peterborough; pop. in 1851, 3,183. It is a place of much interest to antiquaries, partly for its curious triangular foot bridge, dating from the reign of Edward II., but chiefly on account of the ruins of a famous and magnificent abbey, a portion of which is still used as a church. This abbey was founded by Ethelbald, was several times destroyed, and rebuilt each time with greater splendor than before.

CRUCIBLE, a small vessel made of refractory materials for withstanding high temperatures, and used in metallurgic and chemical operations for containing substances to be melted. The name is said by some to have been given to them by the alchemists from the Latin *crux*, *crucis*, in consequence of their custom of marking them with the sign of the cross. Others derive it from the Latin *crucio*, to torment, because the contents, in the language of the same alchemists, were thus treated in the operations to which they were subjected. They are made in various forms and of different materials, according to the purposes required of them. The qualities they should possess are infusibility, capacity of bearing sudden changes of temperature without breaking, resistance to the chemical action of the substances fused in them, and a texture impermeable to liquids and gases. But substances which possess some of these qualities are deficient in others, and consequently they are differently made for dif-

ferent uses; and when made of one material as the best to withstand the heat or the most economical, they are lined with another which better resists the chemical action of the substances to be operated upon. Charcoal being one of the most unalterable substances known, when protected from the action of the air, it was much used for crucibles by the old assayers; a piece of proper shape was merely hollowed out and bound round with wire. An improvement upon this is to line earthenware crucibles with charcoal, well selected, so as to be free from impurities, and after being pulverized passed through a very fine sieve, and made into a paste with water. This being thoroughly kneaded, the crucible, moistened by dipping it in water, is filled with the paste by ramming in small portions at a time with a wooden pestle. Out of this filling a cavity of proper size for the operation is excavated with a spatula, and its sides are well rubbed and smoothed with a glass or metallic rod. For many purposes these, called brasqued crucibles, are the best of all. The lining of charcoal strengthens the sides, so that they will not be liable to lose their shape by softening in the fire; the earthenware is protected by it from contact with the contents; and it is out of reach of the action of the air. Moreover, in reducing the oxides of the metals the charcoal affords the carbon required by the oxygen to disengage it from its metallic combinations, and convert it into the volatile form of carbonic acid gas.—The best earthenware or porous crucibles are made of the purest clays, such as consist only of alumina and silica. The texture depends upon the degree to which the materials are pulverized. The close Wedgwood crucibles are made of the best materials finely ground; but they do not withstand sudden changes of temperature so well as the coarser Hessian and English crucibles. The former, which have been long known as the cheapest and among the best clay crucibles, are made in the vicinity of Almerode, in Germany, of an aluminous clay, which is mixed with quartz sand. They are 3-sided at top and round below. Their composition, according to Berthier, is silica 70.9, alumina 24.8, oxide of iron 3.3, with traces of magnesia. They are remarkable for their refractory properties of withstanding sudden changes and high degrees of temperature. Small ones may even be heated to redness and thrown into cold water without breaking. They will soften, however, at the high heat of the furnaces in which they are used, and the coarseness of their material renders them very porous. Saltpetre and common salt, and other substances used as fluxes, are liable when fused to find their way through them. Porcelain or Wedgwood crucibles are more impervious to vapors and fluxes. The French crucibles of Beaufay are perhaps more refractory than the Hessian. They are made near Namur, of clay without additional mixture of sand; when moulded they are washed over with a thin coating of pure clay, prepared by pulverizing clay that has been baked. They are of more dense material than other clay crucibles, and hence better resist the passage of fluxes. Their composition is, by the analysis of Berthier, silica 64.6, alumina 34.4, oxide of iron 1. The English or London crucibles are made of triangular or circular form, and have covers of the same material. The Cornish crucibles made for the use of the assayers of the copper ores in Cornwall are cylindrical, and resemble in their properties the Hessian. Stourbridge clay, the material of fire brick, is used for the manufacture of crucibles, mixed with half its weight of pulverized coke.—Blue pots, or black lead crucibles, as they are often incorrectly called, are made of the mineral graphite or plumbago, which is composed of carbon with 4 to 10 per cent. of iron. The substance is finely pulverized, mixed with a third or half its weight of clay, moulded into the pots, some of which are large enough to serve for assaying furnaces, and then baked. These are excellent crucibles for resisting changes of temperature, as well as the chemical action of their contents; but their higher cost limits their use to certain purposes only. They are used in melting cast steel in the large works where this is manufactured. They may be protected on the inside from the action of the oxides, which tend to remove the carbonaceous material, by a lining of clay or other substance. These are made of excellent quality in Boston and in Jersey City.—For different chemical operations crucibles are employed made of various metals. Those of platinum are in continual use in the operations connected with chemical analyses. But these, though they bear the highest temperature, are attacked by many substances which do not affect other metals, as silver particularly, and crucibles of this material are therefore required as occasional substitutes. Cast-iron crucibles are cheaply made, and are very serviceable in many assays of sulphurets especially. The iron itself serves to desulphurize the natural compound of this substance, as the carbon of the brasqued crucibles deoxidizes the oxides. Assays of galena may be rapidly made one after another in cast-iron crucibles, by introducing a portion mixed with twice and a half its weight of carbonate of soda and fusing; the galena is decomposed, and sulphuret of iron is produced at the expense of the crucible; the lead set free may be poured out, and a new portion instantly introduced, and thus the operation may be continued as long as the crucible lasts.

CRUCIFIX (Lat. *crucifigo*, to fix to a cross), a sculptured or carved representation of the Saviour attached to the cross. The simple cross was the earliest symbol of Christianity. The 6th œcumenical council (680) ordered that Christ should be represented according to his human features, rather than in the symbolical figure of the paschal lamb, and in the succeeding century the crucifix became common throughout the church. There are still preserved in a museum in Rome crucifixes which date from the 8th century. This image is used by few Protestants,

but is placed by Roman Catholics in churches and oratories, especially on altars, and is sometimes worn on the person.

CRUCIFIXION, a mode of punishment which existed among several ancient nations. Thucydides speaks of Inacus, an African king, who was crucified by the Egyptians. Polycrates suffered the same fate from the Persians, according to Herodotus. It was common among the Carthaginians. Alexander the Great made a most ferocious use of the cross after the capture of Tyre on the defenders of that city. King Tarquin the Proud is said to have been the first to cause executions in this way at Rome. The survivor of the 3 Horatii had been previously condemned to this punishment for the murder of his sister, but had been pardoned. It was an infamous punishment, applied especially to slaves, and hence termed by Tacitus *servile supplicium*. The cross was usually raised in some frequented place outside of the city. In Judæa this kind of execution was practised under the Romans. The crucifixion of the Saviour is a favorite subject with the great painters of the middle ages.

CRUCIGER, Kaspar, a German Protestant theologian, born at Leipsic in 1504, died at Wittenberg in 1548. He studied at Wittenberg, where he became connected with Luther, by whose favor he was appointed to the rectorate of Magdeburg in 1524. In 1528 he became professor of theology and court preacher at Wittenberg, in which offices he remained till his death. His services to the reformation consist chiefly in his having aided Luther in translating the Bible, and having taken part in the most important religious conferences of the time.—His grandson, Georg (1575–1637), was the instructor of Maurice of Hesse, and persuaded that prince to embrace the reformed doctrines. He was afterward professor of philosophy at Marburg, and in 1618 attended the council of Dort.

CRUDEN, Alexander, author of the "Concordance" to the Bible, born in Aberdeen, Scotland, May 31, 1700, died in London, Nov. 1, 1770. He was educated at Mareschal college, and intended for the church, but was employed for 10 years as teacher. In 1732 he went to London, where he was engaged as corrector of the press by a publishing house, with which occupation he combined that of a bookseller, opening a small shop under the royal exchange. He had already commenced his "Concordance to the Holy Scriptures," which was completed and published in 1737, and dedicated to Queen Caroline, from whom he hoped for some substantial proof of royal munificence, a hope never realized; the queen died in 16 days after the presentation of the work. Cruden was afflicted with a peculiar mental malady, and 3 times in his life he was confined in a lunatic asylum—once soon after his departure from college, again immediately after the publication of his "Concordance," and a third time 15 years later in 1753.

CRUGER, John Harris, commander of a corps of royalists in the war of the American revolution, born in New York in 1738, died in London in 1807. In 1764 he was mayor of the city of New York and speaker of the colonial assembly. He was a member of the colonial convention called in the next year to resist the stamp act, and composed the declaration of rights. After the outbreak of the war he adhered to the crown, held the commission of a lieutenant-colonel, and conducted in 1781 the gallant and successful defence of Fort Ninety-six, S. C., when it was besieged by Gen. Greene. His corps formed the British centre in the battle at Eutaw Springs.—His brother, Henry Cruger, born in New York in 1739, died in the same city, April 24, 1827, established himself in trade in Bristol, England, and in 1774 was elected to the British parliament, having Edmund Burke for his colleague. He advocated on all occasions a conciliatory course toward the Americans.

CRUIKSHANK, George, an English humorist, born in London in 1794. His father Isaac Cruikshank, and his elder brother Robert, were caricaturists and engravers, and he picked up a knowledge of the art from seeing them work. He was admitted a student of the royal academy under the superintendence of Fuseli; but finding the rooms uncomfortably crowded, he gladly accepted an offer from a publisher to illustrate juvenile books and make cheap caricatures. Cruikshank was an enthusiastic liberal, and the first objects of his satire were political. For several years, to use his own words, he "lived upon the great usurper Bonaparte." He soon became known as a clever political caricaturist, and was employed by a number of publishers; but the works which first gave him an extensive popularity were the illustrations to a series of squibs on the public and private life of the prince regent, published by Hone between 1819 and 1821, and entitled the "Political House that Jack built;" the "Matrimonial Ladder," and *Non mi ricordo*, in allusion to the marriage and trial of Queen Caroline; the "Man in the Moon," &c. The artist was most successful in the humor of his illustrations, and such was the excited feeling of the time and the cleverness of the satire, that some of the pamphlets reached a sale of 200,000 or 300,000 copies. After this Cruikshank abandoned political caricaturing, having first projected a work to illustrate the results of what was called "seeing life." The story, written by Pierce Egan, had an extraordinary sale in England and America, under the title of "Life in London;" but as the moral aim of the artist was entirely overlooked by the author, Cruikshank retired from the work before its completion. From 1824 until the present time Cruikshank has been almost incessantly engaged in illustrating books; a complete collection of which would exhibit a fertility of invention and humor, a dramatic power, and a technical excellence which have seldom been combined in one artist. So prolific, however, has been his pencil, that it is hardly possible to give a complete list of his

works; he himself has not prints of the whole of them. Among those which obtained the greatest popularity are "Points of Humor," "Mornings at Bow Street," Fielding's "Tom Thumb," "John Gilpin," the "Epping Hunt," "Three Courses and a Dessert," "Sunday in London," which has a satirical humor not unworthy of Hogarth, Fielding's, Smollett's, Defoe's, and Scott's novels, "My Sketch Book," "Illustrations of Phrenology," "Illustrations of the Time," &c., &c. In 1835 he commenced the "Comic Almanac," which was for many years the vehicle of some of his happiest designs. He also illustrated Dickens's first work, "Sketches by Boz," and subsequently "Oliver Twist," which originally appeared in "Bentley's Miscellany," while under the control of Dickens. For the same magazine, after it came under the editorship of Ainsworth, he furnished the designs for "Jack Sheppard" and "Guy Fawkes," and upon the establishment of "Ainsworth's Magazine" illustrated several novels by Ainsworth which appeared there serially. He subsequently started a periodical of his own, called the "Omnibus," which was edited by the late Laman Blanchard. His illustrations of Maxwell's "History of the Irish Rebellion," published about this time, afford some happy specimens of his efforts in a serious style. In 1847 appeared "The Bottle" in a series of 8 prints, by many deemed the most important work of his life, and of which the germ can be traced in the "Gin Shop," the "Upas Tree," the "Gin Juggernaut," and others of his earlier works. The striking manner in which the evils of intemperance were depicted made the work immensely popular, and many thousand copies were sold at a shilling each. The artist subsequently published a sequel in which the career of the son and daughter of the drunkard was followed up. Since the publication of these prints Cruikshank has been a determined advocate of total abstinence from intoxicating drinks, and has done good service in that behalf with pen and pencil in his pamphlet, "The Glass." Of late years he has illustrated few noticeable books, but his etchings for the "Life of Sir John Falstaff," by Robert B. Brough, published in 1858, are executed with a delicacy and spirit worthy of his best years. At nearly 60 years of age Cruikshank again applied for admission as a student at the royal academy, and has latterly given much attention to oil painting. He contributes to the annual exhibitions in London, and in several of his pictures has shown great aptitude for this new branch of his art. Few artists of the present day have given more attention to etching, and his plates frequently present a vigor of touch and a breadth of chiaroscuro recalling the efforts of the old engravers. He has been much addicted to athletic sports, and from his dramatic abilities was selected as one of the actors in the amateur performances undertaken by Dickens and others in organizing the guild of literature and art.

CRUIKSHANK, William, a Scotch anatomist, one of the medical attendants of Dr. Johnson in his last illness, born at Edinburgh in 1746, died in London, June 27, 1800. After having studied from 1764 to 1771 at Glasgow, he went to London with a letter of introduction to the celebrated William Hunter, who appointed him librarian, and afterward his assistant. After Dr. Hunter's death, he continued in concert with Dr. Baillie to preside over his school. His "Anatomy of the Absorbent Vessels," which appeared in 1786, attracted much attention among medical men in England and on the continent. In opposition to the views of Haller, he asserted that when portions of nerves are cut out of living animals they may be reproduced. His paper on this subject was published in the "Transactions" of the royal society for 1794. His memoir on the yellow fever, which toward the end of the 18th century prevailed in the United States, and especially in Philadelphia, was published in the latter city in 1798. He is the author of other medical writings, of which the most important are those on insensible perspiration.

CRUSADE (Port. *cruzado*), a Portuguese coin, either of gold or silver, named from the cross, and palm leaves arranged in the form of a cross, which figure upon it. The first crusades were struck off in 1457, on the publication of a bull by Pope Calixtus III. for a crusade against the Turks. The crusades are called old or new, according as they were struck before or since 1722, the former being valued at 400 rees (about 60 cents), and the latter at 480 rees.

CRUSADES (Fr. *croisade*), the name given to the expeditions by which the Christian nations of Europe, in the 11th, 12th, and 13th centuries, sought to recover Palestine from the Mussulmans. The Holy Land was among the early conquests of the Saracens, the caliph Omar having taken Jerusalem A. D. 637. Thus all the places most sacred in the eyes of Christians passed under the control of the votaries of a new religion; and though some of the Saracenic rulers were men of liberal ideas, and of liberal practices as well, and treated pilgrims humanely, others were of different character, and behaved tyrannically. The Abbassides were a superior race, and the most famous caliph of that line, Haroun al Rashid, sent the keys of Jerusalem to his great occidental contemporary, Charlemagne, which assured the safety of Christian visitors to that city. The holy sepulchre and the church of the resurrection were in the hands of the Christians; and the tribute exacted from the Christian inhabitants and pilgrims was small. The Fatimite caliphs, who became masters of Jerusalem in the 10th century, pursued the liberal policy of the Abbassides until the time of Hakem, who was a fanatic, and persecuted the Christians, interfered with the pilgrims, and defaced the holy places. His conduct excited much indignation in the West, which abated when his successors returned to the wiser course of his predecessors. The church and the sepulchre assumed their former state, and pilgrimage became more common than ever, embracing

men of every condition, from great churchmen and nobles to peasants, and women of all ranks. The Fatimite or Egyptian caliphs, though they never again sought deliberately to put a stop to pilgrimage, did not always protect the pilgrims, who had much ill usage to complain of, and who made it known to all Christendom. When the Seljook Turks conquered Palestine, they inflicted all manner of atrocities on the Christian residents, and treated pilgrims with great indignity and cruelty. While the rage that this caused throughout Europe was at its height, the Byzantine emperor, Michael VII., fearing that the Turks would take his capital, sent an embassy to Gregory VII. entreating assistance. The pope addressed the rulers of the European states, urging war on the Turks, and foreshadowing the crusades. Again Alexis Comnenus sent a similar embassy to Urban II., when events were precipitated by the action of an obscure man. Peter the Hermit, who had become imbued with deep religious enthusiasm, was a monk, and by birth a Picard. Visiting Jerusalem, after having led the life of an anchoret, he was an eye-witness of the insults and cruelties of the Turks, and experienced some of them. He was soon possessed of the idea that he was to become the deliverer of the holy sepulchre, and told the patriarch of Jerusalem that he would cause the western nations to drive out the infidels. The patriarch gave him letters entreating aid, and Peter visited Urban II., who saw that he was an enthusiast, and not the less likely to move Christendom because of his austerity, vehemence, and humble condition. The pope encouraged him, and Peter departed to preach a crusade in Italy and France, which he did with such effect that all other business was neglected, and the minds of men of all degrees were most powerfully affected. Peter had an eloquence suited to his purpose, but he could have effected little if he had not found material on which to act. Christendom then had but little light, but it had much sincerity, and it felt the disgrace involved in allowing the Holy Land to remain in the hands of the Turks. Pilgrimages had become so common that they were made by companies of thousands; and their violent interruption was everywhere felt and resented. Human policy turned religious zeal to a useful purpose. Those statesmen who were capable of taking a broad view of affairs may have thought that there was great danger that the Mussulmans would come to the West if the Christians should not go to the East. The pope wished to bring the Byzantine empire into the Latin fold. He held a council at Piacenza, A. D. 1095, which was numerously attended, and at which the Byzantine envoys pleaded their country's cause. It was determined to hold a more general council, which met at Clermont, Nov. 1095, and where French, Germans, Italians, and others were present. The pope's eloquence was so effectual that the multitude exclaimed: "God wills it! God wills it!" when he declared the holy war was commanded from on high. The pope suggested that those who entered on the enterprise should assume the cross on the shoulder or breast. This was agreed to, and the first clergyman who took it, from the hands of Urban II., was the bishop of Puy. The count of Toulouse was the first temporal prince who assumed the cross. The cross was originally red, but different colors were subsequently adopted by different nations. Every person who assumed the cross was known as a *croisé*, or crusader, whence the name of the enterprise. The crusading spirit spread over Britain and the northern nations, much inflamed by the decree passed at Clermont that whoso should go on the expedition should be regarded as having performed all penances. It was to be a pilgrimage on the largest scale, with the pilgrims armed. The spirit was shared by all classes, and by people of every description, including the worst criminals. The number that assumed the cross was almost incalculable. In the spring of 1096 a large body of the lower orders, under the lead of Peter the Hermit, began the march across Germany. They were compelled to divide, and the smaller party, led by a Burgundian knight, Walter the Penniless, going in advance, was annihilated in Bulgaria. The larger party suffered severely, and was guilty of great atrocities, but Peter brought the bulk of it to Constantinople, where he was joined by Walter. They were landed in Asia, where they were nearly all destroyed by the Turks, Peter having left them. A 3d division, consisting of Germans, was led by a monk named Godeschal, and was massacred in Hungary. A 4th, estimated at 200,000, and composed of various peoples, was led by some nobles, from Germany, but it was destroyed by the Hungarians, after having perpetrated terrible outrages. The real crusade was a very different undertaking from these rabble gatherings. No king joined it, but it was headed by a number of eminent feudal princes—Godfrey of Bouillon, duke of Brabant, Robert, duke of Normandy, Hugh, count of Vermandois, Raymond, count of Toulouse, the counts of Flanders and Chartres, Bohemond, prince of Tarento, Tancred, and others. Godfrey, who was one of the first characters of the age, is often mentioned as the leader of the crusading hosts, but he held no such position, though much was conceded to him. After many adventures, including contests with the Greeks, to whose emperor most of the chiefs took the oath of fealty, the crusaders were united in Asia Minor, where they besieged Nice, which surrendered to the Greeks. Their first great encounter with the Turks took place at Dorylæum, July 4, 1097, and, after a long doubtful contest, ended in their victory. Pursuing their march, thousands died of privation, and many more lost their horses. Had the Turks then vigorously assailed them, they would have been destroyed. Antioch was besieged, and taken after many months, but less through crusading valor than by the treachery of a citizen, June, 1098. Here the victors were besieged in their

turn by a great Mussulman army, gathered from different parts of the East, and which had failed to take Edessa, where Baldwin, brother of Godfrey, had established a principality. The crusaders were apparently on the eve of destruction, when they were saved by a revival of the enthusiastic spirit in which their undertaking had originated. It was declared that the steel head of the lance that pierced the Saviour was found under the altar of the church of St. Peter, and its possession was regarded as an assurance of that victory which the invaders won soon after, the Mussulman forces being destroyed or driven off. This victory was the consequence of dissensions among the Mussulmans. Months elapsed before the original purpose was resumed, and then but 21,500 soldiers marched upon Jerusalem, 1,500 only being mounted. Meeting with no resistance, they arrived before the holy city, which, though valiantly defended, fell into their hands after a siege that closed with an assault, and a massacre of almost unequalled atrocity. Godfrey of Bouillon was chosen first head of the Latin kingdom of Jerusalem, 1099. This event marks the completion of the first crusade, though the war between Christians and Mussulmans was continued, involving the destruction of new immense hosts of Germans, Italians, and French, under the duke of Bavaria and others. When Edessa fell into the hands of the Turks, 1145, Christendom was again aroused, and listened readily to the entreaties for assistance that came from the East. St. Bernard preached a second crusade in France, Germany, and elsewhere. Louis VII. of France and Conrad III. of Germany assumed the cross. The emperor led an immense force by the old route of Hungary and Bulgaria to Constantinople, meeting with the usual Greek treachery. He passed into Asia, but soon lost more than four-fifths of his army, which was betrayed by Greeks into the hands of the Turks. Conrad made his way to Nice, at the head of a small force, where he found Louis with his army. After a variety of adventures, in which the French were nearly destroyed, the emperor and king reached Palestine, and with the fragments of their armies, aided by the templars, hospitallers, and forces of the Latin kingdom, besieged Damascus, where they failed completely. The monarchs returned to Europe. For some years the Christians in Palestine defended themselves with success against the Mussulmans, but the rise of the celebrated Saladin to power in Egypt and Syria was fatal to their cause. Defeated in the battle of Hattin or Tiberias, 1187, they surrendered even Jerusalem to Saladin soon after that event. Tyre was the only place of any consequence which they retained. The news of the fall of Jerusalem caused much excitement in the West. A 3d crusade was resolved upon. The emperor of Germany, Frederic Barbarossa, and the kings of France and England, Philip Augustus and Henry II., took the cross. Numerous bands of Christians soon reached Palestine, and Acre was besieged by an immense host. Saladin aided the besieged from without, and this contest was waged for almost two years. The German emperor had organized a great army, better provided, disciplined, and led than any previous crusading force. This army marched by the usual overland route. In Asia Minor they defeated the Turks, but not without experiencing heavy losses. Frederic lost his life while attempting to cross the Calycadnus in Syria, after which little was done by his army, the relics of which finally reached Acre. Meantime, Richard I. of England (Henry having died in 1189) and Philip Augustus had arrived with their forces at Acre, which surrendered (1191), the crusaders, in violation of their word, butchering 5,000 Mussulmans who had been left in their hands as hostages. Philip Augustus soon withdrew from the crusades, alienated and disgusted by Richard's arrogance; but he left a portion of his army to aid that leader, who marched toward Jaffa, defeating Saladin on his way in a pitched battle. Jaffa was abandoned to him, but this was nearly the term of his crusading career. He wished to proceed immediately to Jerusalem, but was thwarted, and 2 months were lost. The crusaders then marched to Ramla, near Jerusalem, but were forced to fall back. The next year Richard resumed operations, and the city might have been taken if the enterprise had been vigorously pushed. Why it was not, is unknown. Richard retreated to the sea-coast. His last act was to relieve Jaffa, which Saladin had assailed. A truce was agreed to, on terms quite as favorable as the Christians could have expected, access to the holy places at Jerusalem being allowed by Saladin. Thus terminated the 3d crusade. The 4th was of an exceptional character. Intended though it was to injure the Mussulmans, probably it did more to enable the Turks to establish themselves permanently in Europe than any other event. An attempt made to preach a new crusade, after the expiration of the truce between Richard and Saladin, had little success out of Germany. From that country bands of nobles and others proceeded to Palestine, where they served to keep up the remains of the Latin kingdom, frequently defeating the Turks, but accomplishing nothing of consequence. In 1200, Innocent III., an able and aspiring pope, resolved to get up a new crusade. The eloquence of Foulques of Neuilly was employed to excite enthusiasm, and with considerable success. The 4th crusade was now commenced. It was mainly French in its character and composition. The counts of Champagne, Blois, and Flanders, and Simon de Montfort, were the principal leaders. The marquis of Montferrat, in Italy, acted with them, and was followed by many Italians. The crusading spirit extended to Germany and Hungary, in the latter country the king assuming the cross. The French crusaders despatched a deputation to Venice to make arrangements for the transportation of their forces to Palestine by sea. For a reasonable compensation the

Venetians engaged to transport a large army; but when, in 1202, the crusaders assembled at Venice, they could not pay the sum named, whereupon it was agreed that they should, in lieu of money, aid the Venetians to subdue Zara in Dalmatia, which had revolted. This, though not under the command of their chief, the marquis of Montferrat, and in defiance of papal prohibition, they accomplished. The Venetians were commanded by the doge, Enrico Dandolo, then nearly blind, and 93 years old. Montferrat then joined them again. Here the combined forces entered into an agreement with Alexis, son of the deposed Byzantine emperor, Isaac Angelus, to restore the fallen monarch to his throne. The opposition of the pope to this singular undertaking had little effect. The expedition proceeded to Constantinople, which was taken, and Isaac Angelus and his son were raised to the throne. Soon, however, dissensions broke out between the parties to the alliance. The restored princes were compelled to fight their restorers, but against their will, and with no good to themselves; for the Greeks hated them, overthrew them, and placed another member of their family on the throne. Isaac died of terror, and Alexis was slain. The crusaders, affecting to be the champions of the dead princes, waged successful war with the new emperor, besieged and took Constantinople, which they pillaged, and established a Latin empire, the territory conquered being divided between the Venetians and their western associates. The ultimate effect of this crusade was to weaken the principal barrier against Mussulman progress westward, so that when the new Turkish power was established in Asia Minor it experienced but moderate resistance from the side of Byzantium. The 5th crusade, 1216, was the work of Innocent III., and was joined by Hungarians, Italians, Germans, English, and French. Andrew II., king of Hungary, led a large army to Palestine, and, in connection with the dukes of Austria and Bavaria, made one campaign, when he returned home. The Germans remained, and having been joined by others, they transferred the war to Egypt (1218). Damietta was besieged and taken, and the crusaders received large reënforcements from England, France, and Italy. The Mussulmans now offered Jerusalem, and even all Palestine, to the victors, on condition that they should leave Egypt, and most of them were for accepting terms so favorable, and which embraced all that the first crusades had been intended to gain. But the papal legate, and the templars and hospitallers, who were joined by the Italian leaders, were able to bring about the rejection of the offer. After a delay of months the crusaders advanced upon Cairo, but the expedition failed entirely, and they were glad to humble themselves before the sultan, who allowed them to leave the country. The pope, Honorius III., attributed the failure to the emperor Frederic II., who had not kept his crusading vow. It was not until 1228 that the emperor went to Palestine with a small force, he being then excommunicate, the effect of which was much to weaken his offensive power. Yet he did much, and made a treaty with the sultan, by which the Christians were to be allowed to visit Jerusalem freely, and Bethlehem, Nazareth, and other places were made over to them. He was permitted to visit the church of the sepulchre, from the altar of which he took the crown, and put it on his head. Thus the 5th crusade was brought to an honorable termination, and the emperor returned to Germany in 1229. The folly of the Christians soon led to the loss of all the good that Frederic had gained for them. They quarrelled, and some of the independent Mussulman rulers were thereby encouraged to refuse to be bound by the treaty, and were successful in their warfare. Again Europe was filled with complaints. A 6th crusade was proclaimed, but with no good result; and the sultan of Egypt, resolved to be beforehand with his enemies, entered Palestine, and drove the Christians from Jerusalem. Hereupon, the nobility in England and France, in 1238, resolved to go to the relief of Palestine. The French, under various leaders, arrived there first, and achieved some brilliant successes. These were followed by reverses and dissensions, and most of the French left the country. The English then arrived, headed by the earl of Cornwall, brother of Henry III., who was well received by all the Christians, whose affairs he completely reëstablished. Jerusalem and most of the Latin kingdom were ceded to them, and numerous captives were released. Cornwall then departed, having effected a great service, and the 6th crusade, like the 5th, was brought to an honorable end in 1240. The 7th crusade grew out of that vast Mongol movement which terrified the world in the 13th century. The Kharizmian horde, flying before the Mongols, sought refuge in Egypt, but were persuaded by the sultan to attack Palestine. They entered that country, and, in 1242, stormed Jerusalem, perpetrating horrors equal to those which had marked its Christian conquest in 1099. Christians and Mussulmans were compelled to league against them, but they were crushed by the savages and their Egyptian allies. Acre became the refuge of the remnants of the Christians, and was the only place of importance left to the cross. The Kharizmians were soon destroyed or expelled by the Egyptians themselves, who now held Jerusalem. These events had the usual effect on Europe. At the council of Lyons (1245), a 7th crusade was proclaimed. It was, chiefly to France and England that the efforts for forwarding it were confined; for though the king of Norway took the cross, he never drew his sword in its cause, and Germany and Italy were not in a state to afford any assistance. Louis IX. of France, known as St. Louis, was the leader. A large army was assembled at Cyprus, whence, after a long delay, it proceeded to Egypt. The English joined it there. At

first, the crusaders were victorious. Damietta was taken, and they directed their steps to Cairo. Mansoura fell before them, but the rash behavior of some of the French leaders caused them to pay dearly for the victory. The Egyptians resisted bravely and skilfully. Communication between the invaders and Damietta, the base of their operations, was cut off. They were shut up in their camp, where sickness and famine thinned their number. Attempting to retreat, they were utterly routed, and the king and his brothers, with many nobles and knights, became captives. The rest of the army were slaughtered, 30,000 falling in all. The king and his companions were finally released, but not until they had experienced many dangers. Damietta was given up, and large sums were promised to the victors. Most of the survivors regarded the crusade as at an end, and departed from a land which had received them so roughly. Not so Louis, a man of great conscientiousness. He went to Acre, and determined to remain in Palestine. This resolution he maintained for 4 years, exerting himself strenuously for the Christian cause, fortifying several places, and preserving union among the Christians. Compelled by the condition of France to return there in 1254, his departure was followed by Christian dissensions. The templars and hospitallers made open war on each other. The Egyptians, having extended their power over the Syrian Mussulmans, now fell on the Christians. The war lasted for years, and was characterized by constantly occurring Christian reverses, in spite of the valor of the losing party, never more heroically displayed than in that dismal time. At length the Latin principality of Antioch fell in 1268, myriads of Christians being slain, or sold into slavery. Nothing was left but Acre. For the last time Europe was moved to serious exertion, and the 8th crusade was undertaken. Louis IX., undiscouraged by his Egyptian failure, assembled a large force, which sailed in 1270. He landed in northern Africa, near Tunis, influenced by a false report of the dey's conversion to Christianity, and the hope of securing him as an ally. He met with no firm resistance in the field, but the light troops of the Moors harassed the French exceedingly. Sickness raged in the invading ranks, and after crowds of brave soldiers and illustrious nobles had fallen, the king himself died. The French immediately gave up the crusade; but they had been joined by a band of English auxiliaries, headed by Prince Edward, afterward Edward I., and these immediately resolved to proceed to Palestine. Spending the winter in Sicily, they sailed for Acre in the spring of 1271, the last expedition of the kind that ever reached that place. The force was only 1,000 strong, but the name of Plantagenet was great in the East. Sultan Bondocdar, who had been so successful over the Christians, immediately retreated. Edward managed to asssemble 7,000 men, with which force he defeated a large Mussulman army, and then stormed Nazareth, which became the scene of a sweeping massacre. Here he was struck down by disease, and his followers died in great numbers. His life was attempted by an assassin. On his recovery, seeing that success could not be looked for, he concluded a truce of 10 years with the sultan, and departed for his own country; and so ended the last crusade, 177 years from the time the first had been preached. Gregory X. sought to evoke a 9th, but with no success. In 1289 Tripoli, on the Phœnician coast, the last fief of the kingdom of Jerusalem, was taken by Sultan Kelaoun. In 1291 the remnants of that kingdom fell into his hands without resistance, save Acre, which he besieged at the head of an overwhelming force. The greater part of the inhabitants withdrew, but the soldiers of the 3 military orders, and some others, defended it resolutely to the last. The city was stormed, and the defenders massacred, or sold into slavery; 60,000 are said to have been killed or taken, probably an exaggeration.—The most important works treating specially of the crusades are the *Gesta Dei per Francos, sive Orientalium Expeditionum et Regni Francorum Hierosolymitani Historia, a variis Scriptoribus Litteris commendata, edente Jacobo Bongarsio* (2 vols. fol., Hanover, 1611; this is a collection of the ancient histories of the crusades, the principal of which are also found, translated into French, in Guizot's *Collection des mémoires relatifs à l'histoire de France*); Mailly, *Esprit des croisades* (Paris, 1780); Choiseul Daillecourt, *De l'influence des croisades sur l'état des peuples en Europe* (Paris, 1810); Michaud, *Histoire des croisades* (Paris, 1813–'22); Heeren, an essay, *Ueber den Einfluss der Kreuzzüge* (Göttingen, 1803); Wilken, *Geschichte der Kreuzzüge* (Leipsic, 1807–'32); Haken, *Gemälde der Kreuzzüge* (Frankfort, 1808–'20); Sporschill, *Geschichte der Kreuzzüge* (Leipsic, 1843 *et seq.*); Navarrete, *Dissertacion histórica sobre la parte que tuvieron los Españoles en las guerras de ultramaro o de las cruzadas* (Madrid, 1816); and also Mills's "History of the Crusades" (London, 1819), the latter volumes of Gibbon's "Decline and Fall of the Roman Empire," and Procter's "History of the Crusades" (London, 1854).

CRUSENSTOLPE, Magnus Jacob, a popular Swedish author, born at Jönköping, March 11, 1795. He published 3 novels in 1821, which were followed in 1828 by a political work (*Politiska åsigter*), in which he eulogized what he termed the era of liberty, extending from 1719 to 1772. In concert with Hjerta he became in the same year editor of an opposition political paper, but the two collaborators soon separated, each to found a journal of his own. Hjerta established the *Aftonbladet*, which still exists, advocating extreme democratic ideas, while Crusenstolpe became editor, in 1830, of the *Fäderneslandet*, in which he renounced the liberal principles which he had formerly maintained, and which ceased when the patronage of government was withdrawn from it in 1833. In 1834 appeared his *Skildringar ur det inre af*

dagens historia, a piquant melange of truth and poetry on questions of social order, which passed through many editions; and subsequently he purchased the Tessin library, celebrated for its historical manuscripts, from which he took his materials for his *Portefeuille* (5 vols., 1837–'45), and for his *Historisk tafla af Gustav IV. Adolph's första lefnadsar* (1837). For one of his works, *Ställningar och förhållanden*, which reflected upon the government, he was imprisoned for 3 years, a condemnation that resulted in several violent riots. In 1840 appeared the 1st vol. of his most successful work, *Morianen* (6 vols., Stockholm, 1840–'44), a romantic description of the history of Sweden during the Holstein-Gottorp dynasty. This, as well as many of his subsequent novels, has been translated into German.

CRUSIUS, Christian August, a German theologian and philosopher, born at Leuna, near Merseburg, Jan. 10, 1715, died in Leipsic, Oct. 18, 1775. He was educated at Leipsic, where he was professor of theology at the time of his death. He was among the principal opponents of the reigning philosophy of Leibnitz and Wolf, which he challenged at once in the name of reason and faith, asserting its incompatibility with Christian dogmas; and he sought to establish a new philosophical scheme which should be perfectly orthodox. Philosophy is in his view the whole body of rational truths, whose objects are eternal, and is divided into logic, metaphysics, and disciplinary or practical philosophy. He subordinated the scholastic principle of contradiction to that of conceptibility (*Gedenkbarkeit*), founded logic upon psychology, attributed to the soul fundamental faculties and a liberty almost as complete as that of the Deity, and made the certainty of human knowledge consist in an inward constraint and inclination of the understanding, the guarantee of the truthfulness of which exists in the divine veracity. These views are Cartesian; and in regarding time and space not as substances but as modes of the divine existence Crusius approached the theories of Clarke and Newton. His doctrines found many adherents, and were especially combated by Plattner. Though arbitrary hypotheses and mystical views are mingled with them, they are the product of acute thought, and were esteemed by Kant among the happiest attempts that had been made in philosophy. The most important of his publications are: *Entwurf der nothwendigen Vernunftwahrheiten* (Leipsic, 1745); *Logik, oder weg zur Gewissheit und Zuverlässigkeit der menschlichen Erkenntniss* (Leipsic, 1747); and *Anleitung über natürliche Begebenheiten ordentlich und vorsichtig zu denken* (Leipsic, 1774).

CRUSTACEA. The name μαλακοστρακα was given by Aristotle to the soft-shelled aquatic animals, as the lobsters, crabs, shrimps, &c., to distinguish this group from the harder shelled animals, which he called οστρακοδερμα, or testacea—the mollusca of our present system of arrangement. In this system the crustacea constitute one of the classes of the primary division articulata of the animal kingdom, and the term *malacostraca* has been retained for one great section of the class, while another is called the *entomostraca*, or shelled insects. The subdivisions of these sections are variously presented by different authorities. Those of the malacostraca, as given by Milne-Edwards, are generally adopted. They are as follows:

I. *Eyes on peduncles, and movable.*

Orders.

Decapoda. { Brachyoura, short-tailed—as crabs.
Anomoura—as hermit crabs, &c.
Macroura, long-tailed—as lobsters, shrimps, &c.

Stomapoda. { Unipeltata—as squilla.
Bipeltata—as phyllosoma, lucifer, &c.

II. *Eyes sessile and immovable.*

Amphipoda—as gammarus, &c., having feet simple and claw-shaped.
Lœmodipoda—as leptomera, &c.
Isopoda—as oniscus or wood-louse, armadillo, &c.

The entomostraca are divided by the same authority into the

Orders. Branchiopoda.
Phyllopoda—as apus, &c.
Cladocera—as daphnia, &c.

Entomostraca Proper.
Copepoda—as cyclops, &c.
Ostrapoda—as cypris, &c.

Haustellata (suctorial crustaceans).
Aranœiformes—extremities long and slender, adapted for walking.
Siphonostomata—extremities not adapted for walking.
Lernœiformes—extremities rudimentary.

The crustacea are furnished with organs of respiration fitted, unlike those of the other articulata, for use beneath the surface of the water; and they are provided with a shell which is either a horny tegument, as in the case of the shrimp, or a calcareous crust, as in the lobster—not stony like those of the mollusca. It is in fact an external articulated skeleton secreted from their own bodies, and periodically thrown off and renewed by the growth of a new shell. In casting its shield the animal is said to first pine away and become smaller, until at last it readily slips out of its covering. Lobsters have been known, when captured, to effect their escape by thus slipping out and leaving their shell in the hands of the astonished fisherman. Sometimes when caught they voluntarily cast off a limb by which they are held, and which they often can very well spare, having always at least 4 pairs beside a pair of claws. In some genera they are so numerous that the animals approximate to the myriopoda. A lost limb too is replaced, gaining in growth at each moulting, while the body is unconfined. These organs, with those of respiration, and the tail also, are supported by the body; the antennæ or feelers, eyes, and mouth belong to the head. The organs of sight and touch are remarkably well developed; and it is not a little interesting to find in those very ancient representatives of this class, the trilobites, whose period of existence was as remote as that of the formation of the older silurian rocks, the same peculiarities and perfection in the structure of the eye as are seen in the highly complicated organization of that of the fly and the butterfly of the present day. The organs of hearing, it is thought, may be detected in some

of the genera of the decapoda, and the habits of many of the crustacea seem to imply the possession of the sense of smell. The shelly covering corresponds in its protuberances and depressions to the form of the important organs of the body within. The progressive motion of the animals is sometimes by walking, sometimes sidewise, backward, or forward—by climbing, as seen in their progress over the weeds and rocks at the bottom of the water—by swimming, and also by leaping. The lobster, clumsy as he appears, and loaded with his heavy claws, is often seen to dart backward by suddenly flapping his tail toward the thorax, throwing himself a distance of more than 20 feet with the swiftness of a bird or a dolphin. By the perfection of his sight he can dart like a mouse directly into his hole, scarcely large enough to admit his body. The young shrimps on the ebb of the tide are often seen along the shallow margin of the water, as observed by Paley in his "Natural Theology," skipping into the air in such numbers that they resemble a cloud or thick mist hanging over the edge of the water to the height of half a yard. The trilobites were fitted by their organization for swimming just beneath the surface of the water, and with the back downward. Like the crustacean insect, the wood-louse, they possessed the faculty of rolling themselves into a ball as a defence against attack from above. The crustacea are found for the most part in salt water; some species, however, live in lakes and rivers, and a few upon the land. Some of them are of considerable size, the largest being the lobsters; but for the most part they are very small. The salt water is almost filled with varieties of them so minute that they are rarely observed, and it is said that a portion taken up at random will always be found to contain a number of them. Numerous species furnish food for man, and all are preyed upon by the inhabitants of the deep. Some species of the whale subsist upon minute crustacea drawn in swarms into their huge mouths, and caught in the fibrous web that lines them, while the water is ejected. Many of the terrestrial crustacea, as the land crabs, are said to visit the sea periodically to deposit their spawn. They burrow also in the mud and in damp places, and their gills are always moist. The oniscus, or wood-louse, has no such arrangement of the gills, and is consequently confined to damp places. Some species of the anomoura or hermit crabs, known also as soldier crabs, are found living in the sea, and others upon the land. Their singular habits are noticed in the article Crab. The entomostraca are mostly fresh-water insects, many of them microscopic. They subsist upon animalcules and microscopic plants. In their progress from the egg to maturity some of them, as the cyclops, undergo curious transformations. Some live in salt water, and one species, the *branchipus stagnalis*, called also the brine worm, lives in the concentrated solutions of salt, such as those of the brine pans of salt works, which contain 2 lbs. of salt to a gallon of water. This active little shrimp is thought by the workmen to contribute to the purity of the brine. Some, like the fresh-water cyclops, sustain intense cold without injury, being sometimes frozen into the ice, and coming out on its melting as active as ever. Many are parasites, as the lerneas, and are classed by themselves by some naturalists, with the name *epizoa*. The *lerneonemia monilaris* infests the head of the sprat, attaching itself near the eye. It is luminous in the dark, and the fishermen say that a shoal of sprats is often headed by those thus infested, which they call lantern sprats. The cod also, and other large fish of our deep waters, have their parasitical crustacea. The limuli, or king crabs, or "horse-shoes," common upon our coast, are placed by Milne-Edwards in a sub-class, which he calls *xiphosura*. It differs from the other genera by having no organs for conveying food to the mouth. The name is from ξιφος, a sword, with reference to the long, pointed, spear-like appendage usually called the tail. This is used by the natives of the Moluccas to point their weapons. A buckler entirely hides from view the limbs and organs of the animal as he moves along upon the sand, or in the water upon the bottom. They are found as fossils in the strata of the coal and Jura formations of Europe.—The crustacea furnish a great number of species that are much esteemed as food by man, as the lobsters, crabs, shrimp, prawn, &c., and the business of capturing them is extensively pursued along the shores where they abound. Lobsters and crabs are caught in pots, or traps of basket work, made like the wire mouse-trap with conical openings that admit the entrance but not the exit of the animals. These are sunk upon the ledges of rock along the coast, after being baited with refuse fish, each trap having one end of a line attached to it while the other is fastened to a floating buoy. The fishermen visit the traps daily, draw them up, and taking out the animals, sink them again. Immense quantities are caught on the coasts of Norway and Scotland for the English markets, where they are carried alive, being kept in perforated "cars" like small boats, sunk to the level of the surface of the water, the same as are used by our fishermen. The northern markets of this country are supplied with lobsters from Massachusetts bay, about 200,000 being taken annually. They have been caught weighing 28 lbs., but the average size is about 4 lbs. On being thrown into boiling water, the natural black or dark color of the shell is changed into red by the solution of the bluish black pigment diffused through the tegument, and the substitution of a red-colored oil, which is insoluble in water. Lobsters are commonly boiled before they are offered in the market, though it is customary in some places to sell them alive to insure their freshness. They are kept many days by having the gills always moistened. Crabs are taken nearer the shore than lobsters, and many of those which live upon the land are

much esteemed as articles of food. Those caught in the waters of Chesapeake bay are preferred in their soft state, and are regarded as great luxuries. In Europe, where they are also a favorite article of food, they are preferred after the new shell has become hard.

CRUVEILHIER, Jean, a French physician, born at Limoges, Feb. 9, 1791. He studied under Boyer and Dupuytren, was a professor at Montpellier, and became attached to the faculty of Paris in 1825. In 1826 he reorganized the anatomical society, which in 1769 had been founded by Dupuytren. The first part of his great work on pathological anatomy (completed in 1842) appeared in 1829. He has also written on descriptive anatomy, and on the anatomy of the nervous system.

CRUVELLI, Sophie (Baroness Vigier), a German vocalist, born in Bielefeld, Prussia, Aug. 29, 1830. Her family name is Cruwell, which she Italianized into Cruvelli. Her musical education was acquired in Paris, but she made her *début* upon the German stage, to which her reputation was for several years confined. She afterward sang in Milan, Venice, and other Italian cities. In 1852 she made her first appearance in London at the queen's theatre, then under the direction of Lumley, and was successful. Her voice, a soprano of great strength and purity, her dramatic powers, youth, beauty, and commanding person, created an extraordinary enthusiasm in her favor, and both in London and in Paris, which she visited in the same year, she became perhaps the most popular singer of the day. The constant demands upon her voice were beginning to impair its quality, when in the latter part of 1856 she was married to the baron Vigier, since which time she has not appeared upon the stage. Ahmed Pasha, son of Mehemet Ali, lately left her a fortune of 1,000,000 francs, and an almost equal sum in diamonds.

CRUZ, Juana Inez de la, a Mexican poetess, born near the city of Mexico in 1651, died April 17, 1695. She was very quick at acquiring knowledge, and was able to speak and write Latin with fluency. She was only about 17 when she resolved to become a nun, and entered the convent of St. Jerome at Mexico, where she remained until her death. During her life she was called the "tenth muse," and in Spain, where she is known as the "nun of Mexico," her poems have been very popular. Her writings have been collected in 3 vols. 4to.

CRYOLITE (Gr. κρυος, ice, and λιθος, stone), a mineral so named from its fusibility in the flame of a candle. It is a compound of sodium, fluorine, and aluminum, and is used for the preparation of the new metal aluminum. Large quantities are imported into England for this purpose from Greenland, where it was discovered by a missionary and carried many years ago to Copenhagen. It was supposed to be sulphate of barytes, until examined by Abilgard, who found it to contain fluoric acid. Klaproth afterward detected soda. It is a snow-white mineral, partially transparent, of vitreous lustre and brittle texture. Its hardness is 2.5; sp. gr. 3. It cleaves in 3 directions, 2 of which are rectangular. It occurs in veins in gneiss with pyrites and galena, and has been found at Arksut, in West Greenland, and at Miask, in the Urals. At the former place it constitutes a mass 80 feet thick and 300 feet long, included between layers of gneiss, and associated with argentiferous galena and copper and iron pyrites.—See a paper communicated to the geological society by Mr. J. W. Taylor, 1856.

CRYPTO-CALVINISTS, a name given in the latter half of the 16th century to the favorers of Calvinism in Saxony, on account of their secret adhesion to the doctrines of Geneva.

CRYSTAL PALACE, the name of the structure in which the great exhibition of works of industry of all nations was held in London, in 1851. It was erected after a design of Mr. (afterward Sir) Joseph Paxton, on the S. side of Hyde park, opposite Prince's gate, and composed mainly of glass and iron, with its floors of wood. Its length was 1,851 feet; width in its broadest part, 456 feet; area, 21 acres. It contained illustrations of modern industry from about 17,000 exhibitors, was opened May 1, 1851, visited by over 6,000,000 people, closed Oct. 11, 1851, and the building taken down shortly afterward. A new and permanent crystal palace has since been erected (opened June 10, 1854), at a cost of about £1,450,000, 8 m. from London, on Penge hill, near Sydenham, with splendid gardens and waterworks, and arrangements for musical and other public entertainments, and containing, beside industrial exhibitions, an extensive museum of ancient and mediæval art and of minerals, representations of antediluvian animals, specimens in all branches of zoology and botany, and other departments of science.—Crystal palaces, in imitation of that of London, and for the same purpose of universal industrial exhibition, were opened in New York, July 14, 1853, in Munich in 1854, and in Paris, May 1, 1855. The New York crystal palace was situated in Reservoir square, and designed by Messrs. Carstensen and Gildemeister. The main building covered 173,000 square feet, galleries included, with an additional building of 33,000 square feet. It was composed of 45,000 square feet of glass, 1,200 tons of cast and 300 tons of wrought iron, and surmounted by a dome. This beautiful structure was destroyed by fire, Oct. 5, 1858.

CRYSTALLINE LENS, a lenticular transparent body, placed between the aqueous and vitreous humors of the vertebrate eye, at about its anterior third; it is about 4 lines in diameter and 2 in thickness in man, and its axis corresponds to the centre of the pupil. The lens is flat in proportion to the density of the medium in which the eye is habitually placed, being very flat in birds of the highest flight, and very convex in aquatic mammals and diving birds; in fishes it is almost spherical. This most important refracting structure of the eye is imbedded in the anterior portion of the vitreous

humor, and is enclosed in a membranous capsule, to which it is prevented from adhering by the "liquid of Morgagni." Its structure is complicated, but it consists, when fully formed, of fibres arranged side by side, and united into laminæ by serrations of their edges; the fibres originate in cells; the vessels are confined to the capsule, and are derived from the central artery of the retina; when hardened in spirit, it may be split into 3 sections, composed of concentric laminæ; it is made up of 58 parts of water, and 42 per cent. of soluble albumen; the central parts are the densest, and this property increases with age. Beside its refractive power, necessary for distinct vision, it is generally believed that a change in its place, by means of the ciliary muscle and the erectile tissue of the surrounding ciliary processes, is the mechanism by which the eye is adapted to distinct vision at varying distances; beside the anatomical arrangement of the parts, this view is rendered more probable by the development of this muscle in predaceous birds which have a great range of vision, and by the loss of this power of adaptation when the lens of the human eye is removed or displaced in the operation for cataract. For the diseases of the lens and its capsule and their treatment, the reader is referred to the article Cataract.

CRYSTALLOGRAPHY, the science of form and structure in the inorganic kingdom of nature. In the organic kingdoms, the animal and vegetable, each species has a specific form and structure evolved from the germ according to a law of development or growth. In the inorganic kingdom also, which includes all inorganic substances, whether natural or artificial, a specific form and structure belong to each species, and the facts and principles involved therein constitute the science of crystallography. The forms are called crystals; so that animals, plants, and crystals are the 3 kinds of structures characterizing species in nature. As the qualities of crystals depend directly on the forces of the ultimate molecules or particles of matter, crystallography is one of the fundamental departments of molecular physics, and that particular branch which includes cohesive attraction. Cohesive attraction in solidification is nothing but crystallogenic attraction, for all solidification in inorganic nature is crystallization. The solidification of water, making ice, is a turning it into a mass of crystals; and the word crystal is appropriately derived from the Greek κρυσταλλος, ice. The solidification of the vapors of the atmosphere fills the air with snow-flakes, which are congeries of crystals or crystalline grains. Solid lava, granite, marble, iron, spermaceti, and indeed all the solid materials of the inorganic globe, are crystalline in grain; so that there is no exaggeration in the statement that the earth has crystal foundations. The elements and their inorganic compounds are, in their perfection, crystals. Carbon crystallized is the diamond. Boron is little less brilliant or hard; and could we reduce oxygen to the solid state, it would probably (as we may infer from its compounds) have no rival among nature's gems. Alumina is the constituent of the sapphire and ruby, and silica of quartz crystals. Magnesia also has its lustrous forms. The metals all crystallize. Silica and alumina combined, along with one or more of the alkalies or earths, make a large part of the mineral ingredients of the globe, its tourmaline, garnet, feldspar, and many other species, all splendent in their finer crystallizations; and limestone, one of the homeliest of all the earth's materials, as we ordinarily see it, occurs in a multitude of brilliant forms, exceeding in variety every other mineral species. The general principles in the science of crystallography are the following: I. A crystal is bounded by plane surfaces, symmetrically arranged about certain imaginary lines, called axes. II. A crystal has an internal structure which is directly related to the external form, and the axial lines or directions. This internal structure is most obviously exhibited in the property called cleavage. Crystals having this property split or cleave in certain directions, either parallel to one or more of the axial planes, or to diagonals to them; and these directions are fixed in each species. In some cases, cleavage may be effected by the fingers, as with mica and gypsum; in others, by means of a hammer with or without the aid of a knife-blade, as in galena, calcite, fluor spar; in others, it is indistinguishable, as in quartz and ice. In all species, whether there be cleavage or not, crystals often show a regular internal structure through the arrangement of impurities, or by internal lines, striations, or imperfections; and, when there has been a partial solution or erosion of the crystal, there is often a development of new lines and planes, indicating that the general symmetry of the exterior belongs to the whole interior. III. The various forms of crystals belong mathematically to 6 systems of crystallization: the monometric, dimetric, trimetric, monoclinic, triclinic, and hexagonal. The greater part of the crystalline forms may be regarded as based on 4-sided prisms, square, rectangular, rhombic, or rhomboidal in base; and the rest, on the regular 6-sided prism. The 4-sided prisms are either right prisms (erect) or oblique (inclined). Any such 4-sided prism may have 3 fundamental axes crossing at the centre, 1 vertical axis connecting the centres of the opposite bases, and 2 lateral, connecting the centres of either the opposite lateral faces, or the opposite lateral edges. The 6-sided prism is right, and has 4 axes, 1 vertical and 3 lateral. In the right 4-sided prisms, the intersections of the axes are all at right angles; in the oblique, one or all of them are oblique angles. A. Right or orthometric systems. 1. Monometric system: the 3 axes equal, and thus of one kind. The system is named from the Greek μονος, one, and μετρον, measure. The cube, for example, has 3 equal axes with rectangular intersections; the axes connect the centres of the opposite faces. The regular oc-

tahedron, rhombic dodecahedron, and tetrahedron, are other solids of this system. The octahedron is contained under 8 equal equilateral triangles, and is like two 4-sided pyramids placed base to base. The lines connecting the apices of the solid angles are the axes; as in the cube, they are 3 in number, equal in length, and rectangular in their intersections. The rhombic dodecahedron is contained under 12 equal rhombic faces, and is an equilateral solid like the cube and octahedron. All the forms of the monometric system are thus equilateral, and every way symmetrical. No one of the axes is distinguished as the vertical. Examples: garnet, diamond, gold, lead, alum. 2. Dimetric system: the vertical axis unequal to the lateral, and the lateral equal; the axes thus of 2 kinds. The dimetric system is named from the Greek δις, twice, and μετρον, measure. The square prism is an example. As the base is a square, the lateral axes, whether connecting the centres of opposite lateral faces or edges, are equal; while the vertical may be of any length, longer or shorter than the lateral. Under this system, there are square octahedrons, equilateral 8-sided prisms, and 8-sided double pyramids, beside other forms. Examples: idocrase, zircon, tin. 3. Trimetric system: the vertical axis unequal to the lateral, and the lateral also unequal, or, in other words, the 3 unequal. The trimetric system is named from the Greek τρις, 3 times, and μετρον, measure. In the rectangular prism (a right prism with a rectangular base), the 3 axes are lines connecting the centres of opposite faces, and are unequal. In the right rhombic prism the vertical axis connects the centres of the bases, and the lateral, the centres of the opposite lateral edges. They have the same relations as in the rectangular prism; that is, they are rectangular in their intersections and unequal. Of the 2 lateral axes in this system, the longer is called the macrodiagonal, and the shorter the brachydiagonal. Examples: sulphur, heavy spar, epsom salt, topaz. B. Oblique or clinometric systems. 4. Monoclinic system: one only of the intersections oblique. This system is named from the Greek μονος, one, and κλινω, to incline. If we take a model with 3 unequal axes arranged as in the trimetric system, and then make the vertical axis oblique to one of the lateral, we change the system into the monoclinic. While the right rhombic prism belongs to the former, the oblique rhombic prism, and other related forms, belong to the latter. Examples: borax, glauber salt, sugar, pyroxene. 5. Triclinic system: all the 3 intersections oblique. The system is named from τρις, 3 times, and κλινω, to incline. The forms are oblique prisms contained under rhomboidal faces. The axes, whether connecting the centres of opposite faces or of opposite edges, are unequal, and all the intersections are oblique. Examples: blue vitriol, axinite. C. The axes 4 in number. 6. Hexagonal system. In the regular hexagonal prism, the vertical axis connects the centres of the bases, and the 3 lateral, the centres of the opposite lateral faces or edges. Examples: beryl or emerald, apatite. Beside the hexagonal prism, the system includes the rhombohedron and its derivative forms, inasmuch as the symmetry of these forms is hexagonal. The rhombohedron is a solid, bounded like the cube by 6 equal faces equally inclined to one another, but those faces are rhombic, and the inclinations are oblique. The relations of the rhombohedron may be explained by comparison with a cube. If a cube be placed on one solid angle, with the diagonal from that angle to the opposite solid angle vertical, it will have 3 edges and 3 faces meeting at the top angle, and as many edges and faces, alternate in position, meeting at the opposite angle below; while the remaining 6 edges will form a zigzag around the vertical diagonal; these 6 edges might be called the lateral edges, and the others the terminal. The cube, in this position, is in fact a rhombohedron of 90°. If the cube were elastic, so that the angles could be varied, a little pressure would make it a rhombohedron of an angle greater than 90°, that is, an obtuse rhombohedron; or by drawing it out, it would become a rhombohedron of an angle less than 90°, or an acute rhombohedron. The diagonal here taken as the vertical axis, is the true vertical axis of the rhombohedron; and as there are 6 lateral edges situated symmetrically around it, there are 3 lateral axes crossing at angles of 60°, as in the regular hexagonal prism. Examples: calcite, sapphire, quartz. IV. The relative values of the axes in any species are constant. In the monometric system, the axes are equal, and the axial ratio is, therefore, that of unity. Calling the 3 axes a, b, c, it is in all monometric species $a : b : c = 1 : 1 : 1$. In the dimetric system the vertical axis (a) is unequal to the 2 lateral (b, c). Calling the lateral 1, the vertical may be of any length greater or less than 1; and whatever the value, it is constant for the species. Thus in zircon, the value of a is 0.6407, and the axial ratio is $a : b : c = 0.6407 : 1 : 1$. In calomel, the ratio is 1.232 : 1 : 1. In the trimetric system, the 3 axes are unequal, but the ratio is constant for each species, as in the dimetric. Taking the shorter lateral axis (b) as unity, the ratio for sulphur is $a : b : c = 2.344 : 1 : 1.23$; for heavy spar, 1.6107 : 1 : 1.2276. In the monoclinic system, the obliquity of the prism is a constant, as well as the relative values of the axes. In glauber salt, this inclination is 72° 15′, and the ratio of the axes is $a : b : c = 1.1089 : 1 : 0.8962$. In the hexagonal system, as in the dimetric, the vertical (a) is the varying axis; but its value is constant for each species. In quartz, $a : b : c : d = 1.0999 : 1 : 1 : 1$; in calcite, 0.8543 : 1 : 1 : 1. In other words, taking the lateral axes at unity, the vertical (a) in calcite is 0.8543. Crystallography owes its mathematical basis to this law. The constancy of angle for each species, stated in § II., is here involved. V. Each species, while having a constant axial ratio, may still crystallize in a variety of forms. Thus the diamond, which is mono-

metric, occurs in octahedrons, in dodecahedrons, and in solids like octahedrons, but having low pyramids of 3 or 6 faces in place of each octahedral face (called tris-octahedrons and hex-octahedrons), and in various combinations of these forms. So dimetric species, as idocrase, may occur in simple square prisms, or in square prisms with the lateral edges truncated or bevelled, or with different planes on the basal edges or angles, or in 8-sided prisms, or in square octahedrons, &c. In the species calcite, the number of derivative forms amounts to several hundreds. This simple fact shows that while cohesive attraction in calcite, for example, sometimes produces the fundamental rhombohedron, it may undergo changes of condition so as to produce other forms, and as many such changes as are necessary to give rise to all the various occurring forms of the species, with only this limitation, that they are all based on the fundamental axial ratio, 0.8543 : 1. VI. In all cases of derivative or secondary forms, either (1) all similar parts (parts similarly placed with reference to the axes) are modified alike, or (2) only half, alternate in position, are modified alike. This law may be explained by reference to a square prism. In this prism there are 2 sets of edges, the basal and lateral; the 2 sets are unlike, that is, are unequal, and included by different planes. One set may therefore be modified by planes when the other is not; moreover, when one basal edge has a plane on it, all the others will have the same plane, that is, a plane inclined at the same angle to the base; or if one has a dozen different planes, all the others will have the same dozen. Again, if a lateral edge is replaced by one plane, that plane will be equally inclined to the lateral planes, because those planes (or, what is equivalent, the lateral axes) are equal; and in addition, all the lateral edges will have the same plane. In a cube, the 12 edges are all equal and similar; and hence, if one of them has a plane on it, there will be a similar plane on each of the 12. Hence, we may distinguish a cube, modified on the edges, however much it may be distorted, by finding the same planes on all the 12 edges of the solid. The 8 angles of a cube are similar, and hence they will all have similar modifications. This remark applies also to the 8 angles of a square prism. The square prism and cube differ in this, that in the cube, when there is one plane on each angle, that plane will incline equally to each of the 3 faces adjoining, because these faces are equal; while in the square prism, the plane will incline equally to the 2 lateral planes and at a different angle to the base. This general law, "similar parts similarly modified," is in accordance with what complete symmetry would require. The exception mentioned, of half the parts modified without the other half, is exemplified in boracite, in which half of the 8 solid angles of the cube have planes unlike those of the other half—a mode of modification that gives rise to the tetrahedron and related forms; in tourmaline, in which the planes at one end of the crystal differ from those at the other; and in pyrites, in which on each edge there is only one plane out of a pair of bevelling planes. All such forms are said to be hemihedral (Gr. ἡμισυ, half, and ἑδρα, face), while the former are said to be holohedral (from ὁλος, all, and ἑδρα). Many hemihedral crystals, when undergoing a change of temperature, have opposite electric poles developed in the parts dissimilarly modified. VII. The derivative forms, under any species, are related to one another by simple multiples of the axial ratios. In calcite, the fundamental rhombohedron has the axial ratio just mentioned, 0.8543 : 1, that is, $a = 0.8543$. There are a number of derivative rhombohedrons among the crystalline forms of this species; one has the vertical axis $\frac{1}{2}a$; another $\frac{1}{4}a$; others $\frac{5}{4}a$, $\frac{3}{2}a$, $2a$, $3a$, $4a$, and so on, by simple multiples of the vertical axis of the fundamental form. So in zircon, of the dimetric system, while a (vertical axis)$=0.6407$, the lateral being unity, there is one derivative octahedron with the axes $a : 1 : 1$; another, $2a : 1 : 1$; another, $3a : 1 : 1$; and there are 3 other forms (8-sided pyramids) whose axes are severally $3a : 3 : 1$; $4a : 4 : 1$; $5a : 5 : 1$; or writing out the value of a, they are $1.9221 : 3 : 1$; $2.5628 : 4 : 1$; $3.2035 : 5 : 1$. It is obvious that if an octahedron of zircon have the vertical axis $2a$ (or the whole ratio, $2a : 1 : 1$), its interfacial angles may be calculated, the value of a being known $= 0.6407$. The calculation is simpler still, provided the basal angle of the pyramid, $a : 1 : 1$, be known; for the tangents of half the basal angles will vary as the vertical axes, or, in this case, will be as 1 : 2. Moreover, if the angles of the octahedron, $a : 1 : 1$, be known from measurement, the value of the axis a may be thence calculated. The derivative forms thus enable us to ascertain the dimensions of the axes of crystals. Crystals are often much distorted, and cubes are thus changed to square prisms, rectangular prisms, and other forms; and prismatic and octahedral crystals are liable to similar distortions. But the distortions seldom affect the angles. These facts still further illustrate the mathematical basis of crystallography. They also show that the modifications which cohesive attraction (or, what is the same, crystallogenic attraction) undergoes in order to produce the various derivative forms of any substance, take place according to a law of simple ratios. VIII. The physical characters of crystals have a direct relation to the forms and axes. Cleavage, hardness, color, elasticity, expansibility, and conduction of heat, differ in the direction of different axial lines, and are alike in the direction of like axes. The difference of color between light transmitted along the vertical and lateral axes of a prism is often very marked, and the name dichroism (Gr. δις, twice, χροα, color), or the more general term pleochroism, is applied to the property. The hardness often differs sensibly on the terminal and lateral planes of a prism, and also, though less sensibly, in other different directions.

IX. The angles of the crystals of a species, though essentially constant, are subject to small variations. The unequal expansion of inequiaxial crystals along different axial directions, alluded to under the last head, occasions a change of angle with a change of temperature; other small variations arise from impurities, or isomorphous substitutions, or irregularities of crystallization. There are also many instances of curved crystallizations which are exceptions to the general rule. A familiar example of curving forms is afforded by ice or frost as it covers windows and pavements. Diamonds have usually convex instead of plane faces. Rhombohedrons of dolomite and spathic iron often have a curving twist; half the faces are concave and those opposite convex. Other imperfections arise from an oscillating tendency to the formation of 2 planes, ending in making a striated curving surface. Thus 9-sided prisms of tourmaline are reduced to 3-sided prisms with the faces convex. X. While simple crystals are the normal result in crystallization, twins or compound crystals are sometimes formed. The 6-rayed stars of snow and the arrow-head forms of gypsum are examples of compound crystals. In the stars of snow there are 3 crystals crossing at middle; in the arrow-shaped crystal of gypsum, 2 crystals are united so as to form a regular twin. Many of these twin crystals may be imitated by cutting a model of an oblique prism in two vertically through the middle, and then inverting one part on the other and uniting again the cut surfaces. In such a twin, the top of one half of the crystal is really at the bottom, and the bottom of the same half at the top. To explain its formation, it is necessary to suppose that the nucleal or first particle of the crystal was a double molecule made up of 2 molecules, in which one was thus inverted on the other. Such twins, as well as other facts, prove that molecules have a top and bottom, or, in more correct language, polarity, one end being positive and the other negative, this being the only kind of distinction of top and bottom which we can suppose. Axial lines or directions of attraction are in fact necessarily polar, if it be true, as is supposed, that molecular force of whatever kind is polar. In the case of the compound crystal of snow, the nucleal particle must have consisted of 3 or 6 molecules combined. Those prismatic substances are compounded in this way which have the angles of the prism near 60° and 120°, and for the reason that 3 times 120°, or 6 times 60°, equal 360°, or the complete circle. In a case where this angle is nearly $\frac{1}{5}$ of 360° (as in marcasite), the twins consist of 5 united crystals. In compound crystals of another kind, the composition is produced after the crystal has begun to form, instead of in the first or nucleal particle. A prism, as in rutile, after elongating for a while, takes a sudden bend at each extremity at a particular angle, depending on the values of the axes. In another case, as albite, which is triclinic, a flat prism begins as a thin plate; then a reversed layer is added to either surface; then another like the first plate; then another reversed; and so on, until the crystal consists of a large number of lamellæ, the alternate of them reversed in position, yet all as solidly united as if a simple crystal. Such a kind of composition may be indicated on the surface in a series of fine striations or furrows, each due to a new plane of composition; and they are frequently so fine as to be detected only by means of a magnifying glass. This mode of twin is additional proof of the polarity of the crystallogenic molecule. If there were not some inherent difference in the extremities or opposite sides of the molecules or their axes, which is equivalent to polarity, there could not be this series of reversions during the formation of the crystal. External electric or other influence may be the cause of the reversion. XI. While simple and twin crystals form when circumstances are favorable, in other cases the solidifying material becomes an aggregate of crystalline particles. Regular crystals often require for their formation the nicest adjustment of circumstances as to supply of material, temperature, rate of cooling or evaporation, &c.; and hence imperfect crystallizations are far the most common in nature. A weak solution spread over a surface may produce a deposit of minute crystals, which, if the solution continues to be gradually supplied, will slowly lengthen, and produce a fibrous or columnar structure. In other cases, whether crystallization take place from solution or fusion or otherwise, the result is only a confused aggregate of grains, or the granular structure. Under these circumstances, the tendency in force to exert influence radially from any centre where it is developed or begins action, often leads to concentric or radiated aggregations, or concretions. The point which first commences to solidify, or else a foreign body, as a fragment of wood or a shell, becomes such a centre; and aggregation goes on around it until the concretion has reached its limits. Basalt and trap rocks which have been formed from fusion are often divided into columns, and the columns have concave and convex surfaces at the joints or cross fractures, proving that they are concretionary in origin. The centre or axis of each column is the centre of the concretionary structure, and therefore it was the position of the first solidifying points in the cooling mass. The distance therefore between the initial solidifying points determines in any case the size of the columns; and as the columns are larger, the thicker the cooling mass, the distance is greater, the slower the cooling. The cracks separating the columns are supposed to be owing to contraction on cooling. XII. The system of crystallization of a given substance sometimes undergoes a total change, owing to external causes. Carbonate of lime ordinarily crystallizes in rhombohedrons, and is then called calcite; but in certain cases it crystallizes in trimetric prisms, and it is then called aragonite. The aragonite appears to

form when the solution has a higher than the ordinary temperature. This property of presenting two independent forms is called dimorphism. Beside difference of form, there is in all such cases a difference of hardness and specific gravity. Carbon crystallizes in one set of forms, which are monometric, in the diamond, and in another, hexagonal, in graphite. Glass and stone are dimorphous states of the same substance, and the former may be changed into the latter by slow cooling.—*Modes of crystallization.* Crystallization requires freedom of movement among the particles engaged in the process. It may take place: 1. From solution, where a solvent serves to disunite the molecules of a solid, and give them the free movement required. The crystallization of sugar or alum from a concentrated solution is an example of this method. The alum solution is simply set away to cool, and the crystals slowly form and cover any object that may be placed in the solution. With many solutions evaporation cautiously carried on will throw down a crop of crystals. Sea water, on slow evaporation, first deposits gypsum, afterward common salt, and then its magnesian salts. 2. From a state of fusion or of vapor. Heat in this case is the dissevering agent, and the removal of heat permits resolidification. Thus water becomes ice, and aqueous vapor snow; and melted lead, sulphur, and other substances, may come out in perfect crystals. If a mass of melted sulphur, or of bismuth, after it has crusted over, be tapped and the interior run out, the cavity within will be found lined with crystals. Camphor, when sublimed by a gentle heat, condenses again in delicate crystallizations. 3. From long continued heat without fusion. The heat used for tempering steel is far short of fusion, and yet it allows of a change in the size of the grains throughout the mass. Heat has crystallized beds of earthy sediment, and thus changed them into gneiss and mica schist without fusing the rocks; and there is reason to believe that even a low degree of heat long continued is sufficient for these results. By this means statuary marble, one of the earth's crystalline rocks, has been made out of fossiliferous limestones. The white marble of Berkshire, Mass., is of the same formation with the Trenton limestone, a rock full of fossils, in central New York and elsewhere. Such altered rocks are termed in geology metamorphic rocks. Nearly all the gems, and far the larger part of the crystalline rocks of the world, were crystallized by some metamorphic process. Long continued vibration is known to change the crystalline texture of iron, making axles of wheels coarse-grained and brittle. In vibration there is some heat developed, and this may aid in the process. 4. From any circumstances that favor the combination of the elements of a compound. Crystallizations often take place at the moment of the combination.—*Origin of the modifications of crystals.* The particular modifications of form presented by the crystals of any substance sometimes depend on the nature of the solution depositing the crystals, and sometimes on wider terrestrial conditions. Common salt, crystallizing from pure water, almost invariably takes a cubic form; but if boracic acid is present, the crystals are cubes with truncated angles; or if the solution contains urea, the crystals are octahedrons. Carbonate of copper, in course of deposition, has been observed to change the form of the crystals on the addition of a little ammonia, and again to a still different form on adding sulphuric acid. Sal ammoniac ordinarily crystallizes in octahedrons; but if urea be present, it forms cubes. A floating crystal forming in a solution has been seen to assume secondary planes on becoming attached to the sides of the vessel. There are many examples where a substance, as calcite, for a time crystallized under one form, and afterward began a new form around or on top of the first. At Bristol, Conn., 6-sided prisms of calcite have been found surmounted by short, flattened calcite crystals of the variety called nail-head spar. At Wheatley's mine, Phœnixville, Penn., the same species, under the form of the scalenohedron, has been found covered and altered to a 6-sided prism. Such facts prove some change, and probably a change in the nature of the solution supplying the carbonate of lime, the ingredient of calcite. In nature the crystals of a substance over a wide region are often identical in form. The calcite of the Niagara limestone at Lockport, N. Y., in all cases has the form called dog-tooth spar, or the scalenohedron; that of Booneville, N. Y., the form of short hexagonal prisms; that of the Rossie lead mine, a combination of other more complex forms. This is a general fact with regard to the crystallizations in rocks. In massive aggregate crystalline rocks there is a tendency to parallelism in the crystals, and hence, at a granite quarry, it is easier to split the granite in one direction than in others, owing to an approximate parallelism in the cleavage planes of the feldspar. To obtain large crystals artificially from solutions, a large supply of material is of course necessary. The most successful mode is to select certain of the best crystals that have begun to form, and supply them from time to time with new portions of the solution. They will thus continue to enlarge, the crystallizing material tending to aggregate about the ready formed crystals, rather than commence a new crop. Cavities in rocks sometimes contain a vast amount of large crystals. At Zinken in Germany, a single cavity was opened last century which afforded 1,000 cwt. of quartz crystals, one of which weighed 800 lbs. In all such cases the supply of material was gradually introduced; for so little silica is taken up by alkaline waters that the solution of silica filling the cavity at any one time could make but a thin lining over its interior. When water freezes, there is at first a sheet of ice made by the shooting of prisms over its surface. After

this, as the cold continues, the crust increases in thickness by gradual additions to the under surface, thereby causing an elongation of prismatic crystallizations downward. The body of the ice is consequently columnar, although not distinctly so when examined in its firm state. In the melting of the ice of some lakes in spring, as has been observed at Lake Champlain, this columnar structure usually becomes apparent; and it is sometimes so decided, that when the ice is even a foot thick and strong enough to bear a horse and sleigh, the horse's foot will occasionally strike through, driving down a portion of the half-united columnar mass, which may rise again to refill the place as the foot is withdrawn. When in this condition, a gale at night sometimes leads to a disappearance of all the ice before morning. A fact like this illustrates what must be the condition of the earth's crust if it has slowly cooled from fusion. The crystallizing rock material below, as the crust slowly thickened, would not necessarily take columnar forms; but there would be some system of arrangement in the crystals which would be of a world-wide character; and as the cleavable species feldspar is a universal mineral among igneous rocks, the earth's crust would derive some kind of structure—a cleavage structure, it might be called—from these conditions. Crystallization thus pervades the globe, and has had much to do in determining its grander surface features, as well as making gems, solidifying sedimentary strata, and furnishing material for the statuary and architect. It has also afforded man one of his best avenues for searching into nature, opening to view facts on which are based some of the profoundest laws in cohesive attraction, heat, light, and chemistry.

CSÁNYI, László, minister of state during the Hungarian revolution, born in the county of Zala in 1790, executed at Pesth, Oct. 10, 1849, served as an officer in the Napoleonic wars from 1809–'15, was disabled by a wound, and retired to private life. Having become a member of the liberal opposition in his native county, he took part in the Hungarian revolution in 1848, acted as a commissary of the revolutionary government in the attempt to relieve Vienna, and during the retreat of the army of the upper Danube to Pesth, which he was the last to leave, and afterward went to Transylvania in order to organize that province under Hungarian rule. There his severity against the German and Wallachian population brought him into collision with the military commander, Gen. Bem, in consequence of which he was recalled. When the diet had proclaimed Hungary an independent state, he was appointed to a seat in Szemere's cabinet, of which he became the most active member. When Görgey, whom he zealously supported, surrendered to the Russians, Csányi, exhausted and grieved, refused to leave his country. Before the Austrian court martial he frankly confessed his revolutionary principles and acts, and was sentenced to death and hanged.

CSOKONAI, Vitéz Mihály, a Hungarian poet, born at Debreczin, Nov. 17, 1773, died Jan. 28, 1805. He was educated at the college of his native town, and appointed professor of classical literature there in 1795. He was soon, however, expelled from this situation on account of his irregularities. He then commenced the study of the law, which he soon gave up, and during the rest of his life had no regular employment. His works, principally love poems and pieces of a light and lively character, have been published in numerous editions.

CSOMA DE KÖRÖS (Körösi), Sándor, a celebrated traveller and Thibetan scholar, born at Körös, in Transylvania, about 1790, died at Darjeeling in India, April 11, 1842. Of a noble but poor family, he studied gratis at the school of Nagy-Enyed, where at an early age he avowed his intention to make the discovery of the original home of his race, the Magyars, the task of his life. The researches of Klaproth led him to seek the traces of the Ooigoors, a people of central Asia mentioned by Arabian writers. In 1815 he went to Göttingen, where he studied medicine and oriental languages, and on his return finally started (1820) for his great journey of discovery, with scanty means furnished by the liberality of a friend, in the poor dress of a Transylvania countryman, but with the heroic determination of a Columbus. He passed through the Balkan to Constantinople, visited Egypt and Syria, and wrote his first letter to his friends from Teheran, dated Dec. 21, 1820. The resemblance of a number of Thibetan words to Magyar incited him to acquire the language and to visit the country of Thibet. He traversed Little Bucharia, the desert of Gobi, reached the regions of the Himalaya, wandered through its valleys, partly with the English traveller Moorcroft, partly alone, and spent 4 years (1827–'30) in a Buddhist monastery at Kanam, on a high mountain on the confines of Thibet and India. For his maintenance on his travels he relied upon his medical knowledge and the hospitality of the Asiatic people. But his taciturn habits and austere modesty prevented him from communicating, in writing or conversation, the particulars of his travels and extraordinary sojourn among the Buddhists, when he arrived at Calcutta with immense philological collections, gathered in the narrow cells of the snow-bound monastery, and comprising no less than 40,000 Thibetan words. A severe disappointment awaited him here. He had already given up the illusion in regard to the Magyar and Thibetan languages; he now learned with deep grief that his collections, made for the purpose of tracing the Ooigoors, were all superfluous, as his discovered sources were translations of well-known Sanscrit works. But in the eyes of British scholars in India he had discovered incomparably more than was the object of his patriotic researches. He became the oracle of Thibetan literature and Buddhistic science, before him almost *terræ incognitæ*. He was the object of general attention in Calcutta, and Hungary and Transylvania learned from

England the fame of their countryman. But he modestly withdrew from society, and destined the money which he received from home (the diet of Transylvania having voted him an ample pension) for works of science for the institutions of his country. When offered a remuneration by the Asiatic society of Bengal for an elaborate catalogue of the 1,100 Thibetan works of their library, which before had been like sealed books, he declared if he were rich he would willingly pay for the pleasure of the work. With unabated zeal he continued his profound studies of the languages and religions of the East, until he again started in 1842 for the prosecution of his originally intended discovery; but on his journey he was suddenly overtaken by illness. He refused to take medicine, and died without a struggle or a groan. His works are: "Essay toward a Dictionary Thibetan and English" (Calcutta, 1834); "Grammar of the Thibetan Language" (1834); an "Analysis of the Kahgyur," the great sacred book of the Buddhists, published in the 20th vol. of the "Asiatic Researches;" and numerous articles on Thibetan literature in the "Journal of the Asiatic Society of Bengal."

CTENOIDS, one of the 4 orders into which Prof. Agassiz formerly divided fishes, according to the peculiarities of their scales. The ctenoids comprise those which, like the perch family, have hard rough scales, with their posterior edge dentated or serrated; this order has a bony vertebral column, serratures on the gill covers, and generally spines in the dorsal fin. The other orders were cycloids, ganoids, and placoids. The cycloids, of which the salmon and the herring are examples, have soft circular scales and fin rays, and simple head bones, with simple outlines; these, the most numerous of existing fishes, have also a bony vertebral column. There is not any strongly marked division between these orders, which are connected together by many intermediate types, and their general organization is not in harmony with this single basis of difference. The ganoids have angular scales covered with a substance resembling enamel; they include many fossil species, and the sturgeon and gar-pike of the present day, approaching the reptiles in some particulars of bony structure. The placoids, including the sharks and skates, have only enamelled granules in the skin; these are cartilaginous fishes, and have as many gill openings as gills. This system is now abandoned by its author as too exclusive, being founded on a single element of classification; yet he still retains the principle, as indicating certain natural relationships, and hopes, by combining it with the fin system of Cuvier and the anatomical system of J. Müller, and by further researches, to arrive at a truly natural classification of fishes.

CTESIAS, a Greek physician and historian, contemporary of Xenophon, born at Cnidus, in Caria, is supposed to have repaired to the Persian court about the year 416 B. C. He accompanied Artaxerxes II. on his expedition against his brother Cyrus, dressed his wounds after the battle of Cunaxa, and returned to Cnidus in the year 399 B. C. During his residence at the Persian court he formed the design of writing a history of Persia. As physician to the great king, he was allowed access to the state archives, from which he had the opportunity of collecting materials. His work, entitled Περσικα, in 23 books, brought down the history of Persia to the author's own time. It was often quoted by ancient writers. There are many important discrepancies between Ctesias and Herodotus; and recent researches in oriental history show that on most of these points the former is entirely untrustworthy. Only a few fragments of this work are now extant. Of a second work, entitled Ινδικα, we have also a few fragments.

CTESIBIUS, a native of Alexandria, celebrated for his mechanical inventions, probably flourished in the latter half of the 3d century B. C., or the early part of the 2d. He is said to have been the first to apply the elastic force of air as a moving power. He invented numerous machines, among which may be mentioned his clepsydra or water clock, and his hydraulic organ.

CTESIPHON, an Athenian orator of the 4th century B. C., son of Leosthenes. After the disastrous battle of Chæronea he moved that Demosthenes, in consideration of his great services in the cause of the state, and the great sacrifices which had been made in behalf of his country, be honored with a golden crown; whereupon he was prosecuted by Æschines, but was triumphantly defended by Demosthenes himself, who, though not the nominal, was yet the real defendant.

CUBA, the largest of the West India islands, lying at the outlet of the gulf of Mexico, and thence extending E. S. E. into the Caribbean sea. Its W. extremity bends toward the S. W., and approaches within 130 m. of Yucatan. The S. point of Florida is the same distance due N. from its extreme N. portion, which is in lat. 23° 10′ N. Its S. W. portion reaches the lat. of 19° 50′, and is distant from Hayti 48 m., the windward channel flowing between the two islands. Punta de Maysi, the E. point of the island, is in long. 74° 7′ W. from Greenwich, and Cape San Antonio, the W. extremity, is in 84° 57′ 12″. The greatest length of the island, measured through the centre, is given by different authorities from 750 to 793 English miles; the greatest width, 50 m. W. of Santiago, is about 127 m.; from Havana to the S. coast at Batabano, it is only about 28 m. across the island. The area of the island has been variously estimated. In 1825 it was computed by Señor Bauza, at the request of Humboldt, and found to be 3,681 square maritime leagues of 20 to the degree. This included the isle of Pines, on the S. coast, the area of which is 98 leagues. The latest estimates of the area, converted into English statute miles, are from 42,383 to 45,277. The isle of Pines contains beside 810 sq. m., and

other small islands 970, making that of the whole territory belonging to Cuba from 44,163 to 47,057 sq. m. The length of shore line on the S. side is 301 leagues, and on the N. 272 leagues; that of the whole island may be called about 2,000 English miles.—The principal feature in the topography of Cuba is a range of mountains more or less broken, which extends through the central portion of the island from one end to the other. From this backbone the streams flow in short courses to the sea on either side. At the E. extremity the mountains spread over a wider territory than elsewhere, and some of them attain a height of 8,000 feet. From Punta de Maysi to Cape Cruz the range called Sierra del Cobre, or Copper mountains, skirts the S. coast for about 200 miles; and back of it, parallel with the line of this coast, runs the river Cauto toward the W., which empties into the bay of Buena Esperanza on the S. side of the island. This, the longest of the rivers, is navigable for schooners about 60 m. above its mouth. At the W. end the mountains also approach the coast, especially on the N. side. In several other places groups of high hills form the margin of the island; but for the most part low tracts intervene between the central elevations and the shore on either side; and in the wet season these are inundated, and rendered almost impassable by the depth of water and the tenacity of the deep black mud. From Jagua to Point Sabina, on the S. side, the country is a continuous swamp for 46 leagues, and the same may be said of many other less extensive tracts on the N. side. The soil of these districts is a rich alluvial mould, in part derived from the decay of vegetable matter, and in part from the disintegration of the calcareous strata that make up the greater portion of the rock formations which appear along the coast, where this is low, and which compose a large portion of the hills near the sea, or between it and the central axis of the island. These limestone formations are singularly cavernous, and many of the streams, some even of the larger rivers, are swallowed up in their recesses; in the dry season the greater number of them seem thus to disappear wholly or in part. To the facility with which rocks of this character are acted upon by water is owing the extreme irregularity of the coast line, its frequently recurring deep indentations, in fact its numerous harbors, and its capes and islands, which are indeed mostly coral reefs, or limestone ledges of similar nature. The formation of these is seen to be still in progress upon the coast, and the ledges are observed to be filled with remains of shellfish of species now living in the waters. The limestone rocks of the hills are of older date; many are referred by Humboldt to the jurassic period. Others may be seen associated with the mica slates, granitic rocks, and serpentines that make up the central hills of the island, which are of metamorphic character, true marbles; such have been found in the vicinity of Puerto Principe, and probably such are the marbles reported to occur in the isle of Pines. Petroleum springs are sometimes met with flowing out of the limestones; but these are of more frequent occurrence in the serpentines. The metamorphic rocks form a large portion of the island, traversing it from one extremity to the other, and everywhere they are accompanied by ores of copper in small or large quantity. The chief development of these is in the mountains near Santiago de Cuba, where they were known and worked in the 17th century. The mines were however abandoned, and remained neglected for more than 100 years, when they were reopened by Englishmen in 1830. They are situated at Cobre, 9 miles from Santiago de Cuba. The ores, principally pyritous, are in quartz veins in the metamorphic rocks. In 1850 the shipments to Swansea amounted to about 25,000 tons, averaging about 16 per cent. of metal. Up to Jan. 1854, the principal company, called the consolidated copper mines of Cobre association, had divided, since their organization in 1834, £61 12*s.* per share on £40 paid in, and the shares were at a small premium. The royal Santiago mining company, formed in 1837, had paid up to 1848, in dividends, £33 4*s.* per share on £13 paid in; but their mines have since been unprofitable, and in 1853 the shares were assessed. Other copper mines less productive have been worked in other parts of the island, as near Trinidad, between Nuevitas and Puerto Principe, and various other places. Near Villa Clara the copper ores have proved to be argentiferous, $7\frac{1}{2}$ oz. being obtained from the quintal ($107\frac{3}{4}$ lbs.) of ore. Lead, antimony, and chrome have been found near Holguin, but they are not worked. Magnetic oxide of iron is an abundant ore, and is found of excellent qualities, but is nowhere worked. Gold was exported in no very great amount by the early settlers, and has been met with in recent times in the deposits of the rivers Holguin, Escawbray, and others, but not in quantity to encourage further explorations. Coal is not a product of the island; but a highly inflammable substance called *chapapote*, and sometimes bituminous coal (see Bitumen), is met with in masses of extraordinary extent, occupying fissures in the serpentines, and the kindred diorites and euphotides. The varieties from different localities, most of which are near Havana, yield different proportions of volatile matters. Mr. T. G. Clemson found in one sample 63 per cent. and the fixed carbon 35 per cent. Mr. John H. Blake found 50 per cent. volatile, and the ultimate analysis yielded carbon 71.84, oxygen 6.22, hydrogen 8.40, ash 13.5. The abundance of this product, and the facility of obtaining it, have led to its extraction and its employment to some extent, as a fuel for steam and manufacturing purposes. Its composition and cheapness recommend it for the production of gas and lampblack. Several chalybeate and tepid springs near Havana, and those particularly of San Diego, 40 leagues to the S. W., have acquired some celebrity for their supposed me-

dicinal effects. From the analysis given these must be ascribed to sulphuretted hydrogen, and sometimes to iron. Common salt may be classed among the mineral products. It is obtained from the lagoons, along the N. coast principally, which are filled by the high course tides, and retain the salt as the waters evaporate in the dry season. About 100,000 lbs. are thus obtained annually at Point Hicacos and Choco.—The productions of the forests of Cuba are noted alike for their valuable qualities and the beauty they impart to the scenery. Some of the hardwood trees are unsurpassed for durability, and with this property combine excessive hardness and toughness. Few of these varieties are exported or known except in the West India islands; but their importance was long ago appreciated in Cuba, and in the early part of the 18th century led to the establishment of shipbuilding by the Spanish government. From 1724 to 1796 Havana was the great nursery of the Spanish armada, 114 vessels of 4,902 guns being constructed there in that time. The business was abandoned in consequence of its taking employment from the mother country. Among these valuable woods may be named the well-known lignum vitæ; the cocoa wood or cocus, which somewhat resembles the lignum vitæ, and is used for similar purposes, as also for pins and tree nails and for turnery, making excellent flutes; the lance wood, largely exported for carriage shafts, surveyors' instruments, and other uses. Mahogany is so abundant, and the quality of the wood is so superior, that it has been, since its first use in London in 1724, an important item in the exports of the island. Belonging to the same natural order is the *cedrela odorata* of Linnæus, a tree which furnishes the wood known in Europe as the Havana cedar, and there much used, as also in the United States, for the inside of drawers and wardrobes. It is the material of the cigar boxes. Humboldt, citing the several species of palm, of which he enumerates five, remarks that "we might believe that the entire island was originally a forest of palms and wild lime and orange trees. These last, which have a small fruit, are probably anterior to the arrival of the Europeans, who carried there the *agrumi* of the gardens, which rarely exceed 10 or 15 feet in height." Though the forests are extensive and almost impenetrable, they are inhabited by no wild animals larger than the wild dogs. These prowl around the settlements at night, with habits like wolves, which they much resemble in appearance also, and devour calves, pigs, and poultry. The jutia is an animal of the size of a muskrat, which resembles in its habits the porcupine and the raccoon of the northern states, living in the trees and feeding on the leaves and fruits. More than 200 species of birds are known upon the island, and many of them are remarkable for the beauty of their plumage. Fish also are of great variety, and, exposed in the markets, attract the attention of strangers by their singularly bright colors. The waters also abound in crustacea and mollusca, and the huge reptiles, the alligator and sea turtles. Crabs of whitish and disgusting appearance frequent the land near the coast, living in holes. They often enter the houses at night. Every spring they migrate from the N. to the S. side of the island. Insects are numerous and of many troublesome kinds; the most to be feared are the tarantula and scorpion; the most beautiful are the large fireflies or *cocuyos*, which emit a steady mild light, so bright that a few of them confined together under glass and fed with sugar cane serve as a lantern, or enclosed in gauze bags are worn by ladies as sparkling ornaments for their dresses.—Cuba, lying just within the torrid zone, enjoys throughout the year a warm climate; but this is tempered in the summer months by the cool N. E. trade winds, which blow indeed almost every day in the year from early in the forenoon to sunset, and also by the rains which prevail from May to November. The clouds which bring these protect the earth from the fierce rays of the sun, and the atmosphere is cooled by the copious evaporation of the waters. In the elevated districts the heat is rarely oppressive, and in the summer for weeks together the thermometer seldom varies 4° or 5° from 83°. The difference between the mean temperature of the hottest month and that of the coldest is 21.6° in Havana and 14.4° in the interior. Only once in 13 years at Vera Cruz was the thermometer observed so high as 89.6°, and its range for 3 years at Havana was between 61° and 86°. In the winter it has been known to fall in the interior to 50°, and ice has been formed at night after the north winds have prevailed for several weeks; but this must be in consequence of local radiation of heat, as the atmosphere is never cooled to the freezing point. Fires are not required for their warmth, and young children are accustomed to go unclothed throughout the year. Strangers from the north are more sensitive to the changes of the climate than the natives; and during the prevalence of the "northers," or the wind storms from the north, often experience positive discomfort from the cold. In the summer bilious fevers of the yellow fever type are prevalent, but more particularly virulent along the coast than in the interior. From December to May the climate is dry and salubrious, and the roads, which during the hot season were deep with mud, become baked and open in wide cracks by the contraction of their material. There is no record of snow having ever fallen in Cuba except on Dec. 24–25, 1856, when the coldest term ever known on the island was experienced. The thermometer then descended at Havana to 43° F. (lowest previously 50° in Dec. 1826); snow fell near Villa Clara, in the most central part of Cuba, and in the same vicinity ice formed to the thickness of a dollar on the lagoons of a sugar estate. Hail is frequently seen, particularly in the eastern department, between February and July. The only occasion known of its falling at Havana was in

March, 1852. Great thunderstorms occur from June to September, and in the same period silent lightnings are common. Earthquakes seldom occur in the western districts, but are frequent in the eastern, especially in that of Santiago de Cuba. In 1853 that city experienced two violent earthquakes, producing much injury and causing its decline. The salubrity of the climate is variously estimated. Some writers consider it unfavorable to prolonged life. The most remarkable instances of longevity have been found among the negro and aboriginal races.—It is considered by Cuban statisticians that all the reports on the population of the island have been quite incomplete. Some of these estimate that the total population at the present time is about 1,500,000. The portion not reported is believed to consist chiefly of slaves. The following is a synopsis of some of the reported enumerations:

Years.	Whites.	Free Col. and Bl.	Slaves.	Total.
1775	96,440	30,847	44,333	171,620
1827	311,051	106,484	286,942	704,477
1841	418,291	152,838	436,495	1,007,624
1846	425,767	149,226	323,759	898,752
1849	457,133	164,410	323,897	945,440
1853	501,988	176,647	330,425	1,050,000
1857	549,674	174,810	374,549	1,107,491

CENSUS OF 1853.

Classes.	West'n Dep't.	East'n Dep't.	Total.
White persons	397,451	104,537	501,988
Free colored and black	98,442	78,205	176,647
Slaves	268,717	61,708	330,425
Permanent population	764,610	244,450	1,009,060
Floating population, white	....	....	40,940
Total	....	....	1,050,000

The following estimate was made of the classes composing the white population, which, as given above with the floating population, supposed to consist wholly of whites, amounted to 542,988, viz.: 90,000 from Spain, 25,000 from the Canary islands, 3,000 French, 1,000 English, and 3,000 Americans and others, leaving about 421,000 as the number of native whites.

CENSUS OF 1857.

Classes.	West'n Dep't.	East'n Dep't.	Total.
White persons	423,908	125,766	549,674
Free colored and black	94,857	79,953	174,810
Slaves	306,036	66,423	374,549
Aggregate	824,801	272,142	1,096,943
To which is to be added the number of emancipados	.....	....	5,240
Asiatic colonists (or coolies)	....	....	5,308
Total population	....	....	1,107,491

Nearly the whole of the native whites are descendants of the peninsular Spanish races. In the period following the conquest (A. D. 1511), none but Castilians were allowed to come to America; but at present the industrious Catalans or Catalonians, and the hard-working Isleños (islanders of the Canaries), are found to preponderate throughout the island. Until 1801 Spain maintained a commercial monopoly of the island, which system, combined with other features of its government, restricted the settlement of Cuba almost exclusively to Spaniards. The Spanish whites are divided primarily into old Spaniards, or peninsulars, and creoles; and these classes are widely separated by a reciprocal aversion, amounting to hostility, and even hatred. The former hold all the offices, and look down upon the creoles with contempt. They transact most of the commerce, and monopolize the most profitable traffic. The Catalans, industrious, shrewd, hard-headed, and very loyal, faithful to their motto, "Five years of privation and a fortune," are to be found in every town and hamlet, and in every stage of social development. The opulent creole planters and merchants are distinguished for intelligence, enterprise, courteous manners, and genial hospitality.—The African race was introduced in 1524 to serve as slaves. Its natural increase has not corresponded to the analogy of the climate with that of its own country. This result has been owing mainly to the perpetuation of the slave trade, which has kept up a great excess of the male sex, and encouraged the exaction of the greatest possible amount of labor from all the slaves. On the large estates there is some semblance of family life among the negroes, but the children are not often numerous. Even on the best of the sugar estates the slaves (both sexes) work 16 and sometimes 19 hours a day, from November to May, during which season labor is carried on unceasingly, the slaves working by watches in gangs. Upon many of the small tobacco plantations, also, their toil is similarly severe. The slave trade is actively prosecuted in direct violation of the most positive treaty obligations, and the annual importations are estimated at 10,000 to 20,000. The profits of the trade are enormous, and traders can well afford to give large bribes to the officials. When a slaver is captured, her case is adjudicated by the so-called "mixed commission." If a lawful prize, she is retained as such by her captors; and her slaves, styled *emancipados*, are apprenticed, under the charge of the Spanish authorities, for a term of years (8 or 10 to 15), at the end of which they are entitled to freedom. Only a small proportion, however, become free, because the masters to whom they are hired sell them, and at the end of the period report that they are dead. The importation of coolies, or Chinese laborers, was commenced in 1847. Nominally they are "free colonists," but in reality slaves. Professedly they are employed by contract for a term of years, usually 8, "without prohibition of extension for any longer period to fit the life of the subject or the interests of the master." By the close of 1853 about 6,000 had been introduced. From 1853 to April 10, 1855, about 4,000 were landed, and 960 were lost during voyages by disease, suicide, &c. From April 10, 1855, to May 13, 1858, 23,146 were delivered, and 3,844 died on the passage. This makes an aggregate delivery from 1847 to 1858 of about 33,000, with an average mortality on shipboard of over 17 per cent. The introduction of In-

dians from Yucatan, on the "contract plan," was begun about 1853, and met with some opposition from the Mexican and Central American governments. The whole number delivered to May, 1858, was 1,385. The mulattoes form $\frac{3}{5}$ of all the free colored; but of the slaves their proportion is about $\frac{1}{10}$. They generally employ themselves as tailors, carpenters, musicians, coach builders, and painters; and they are usually excellent workmen. There yet exists a poor remnant of the aboriginal race; but the majority of this class are crossed with mulattoes.—Productive industry in Cuba is mainly devoted to agriculture, with direct reference to the exportation of the staples. The manufactures, properly so called, are of little importance; and as a class, the people are disinclined to mechanical pursuits. The mining interests, chiefly in copper, do not contribute so much to the wealth of the island as would at first seem from their extent, since these are worked mainly on foreign account. The fertility of the soil is proverbial, and its actual production has long been highly remunerative; and yet it appears, according to the returns of 1853, that not more that $\frac{1}{19}$ part was then under cultivation. The following table exhibits the distribution of the surface, stated in *caballerias* (the *cabelleria* is equal to about 33 acres):

Description.	West'n dept.	East'n dept.	Total.
Barren lands, mines, &c.....	142,138	179,269	321,407
Mountains, forests, &c.....	174,418	202,584	377,002
Natural pasturage	102,022	47,226	149,248
Artificial "	15,183	5,158	20,341
Under cultivation.....	34,098	14,474	48,572
Total.....	467,859	448,711	916,570

The chief products are the sugar cane, tobacco, coffee, cotton, fruits, and garden vegetables. Rice, sago, maize, and even cacao, are cultivated on a small scale, not enough to supply the consumption of the interior. The lands of Cuba are recognized as superior to those of the other Antilles for the production of the sugar cane; but there is great irregularity in the extent of the cultivation and yield of this staple, depending on soil, weather, condition of plant, &c. Sugar estates, called *ingenios*, are the largest agricultural establishments on the island. Many of them produce 8,000 to 9,000 boxes of sugar (each 400 lbs.), and a few of them are much larger. Their formation requires great outlay, and their management is very expensive; but their production is correspondingly great, and the foreign demand for this crop is steady, so that their owners become immensely wealthy. From 1853 to 1858 the yearly exports of Cuban sugars were from 700,000,000 to 750,000,000 lbs. Most of the tobacco is produced in a very few districts, which are particularly favorable to its culture. The best lands for this plant are comprised in an irregular oblong tract, near the W. extremity of the island, on the S. coast. It is about 73 miles long by 18 wide, extending from the Rio Hondo west to the Cuyaguateje or Mantua river. Outside of this, toward the meridian of Havana, the tobacco is less fragrant, but of fine color, and the latter quality gives it the preference with foreigners. Coffee was for a period (from about 1820 to 1832) the second staple in importance, but afterward its production was greatly decreased, owing to the duties charged on its importation into the United States, and to the competition of Brazil, Java, &c. Cuban coffee, however, is of superior quality. Maize, rice, sago, pulse, yuca, the sweet potato, plantains, and fruit are grown on nearly all estates, and especially on the small farms at some distance from the towns. Maize produces two crops a year, but is quite variable in its yield.—The foreign commerce of Cuba, in proportion to its population, probably exceeds that of any other country on the globe. Since 1850 the valuation of the yearly exports has ranged from $27,000,000 to $32,000,000, and that of the imports has averaged about the same; but it appears that in these valuations the custom or rule is to understate the exports, and overstate the imports. Yet the commerce is much restricted by the policy of the government. The duties discriminate greatly in favor of the Spanish flag in all respects, though chiefly in favor of all imports by Spanish and Cuban vessels, and of imports of products of Spain. The tonnage duties similarly favor national vessels. Under this system, the greater part of the imports since 1829 have been brought under the Spanish flag. Of late years the proportion has averaged two-thirds. The effect of the system may be readily seen in the importation of flour and provisions. Under fair regulations these would mainly be brought from the United States. But the duties on flour are as follows: from Spain in Spanish and Cuban vessels, $2 50 per barrel; from other countries in same vessels, $8 50, and in foreign vessels, $9 50. In 1854 the imports of flour from Spain were valued at $2,677,791; from the United States, $29,830. Under such burdens prices are maintained at high rates, materially diminishing consumption. Duties are collected on exports as well as imports, and the yearly totals of each are about as 1 to 4. Only between $\frac{1}{3}$ and $\frac{1}{4}$ of the exports are carried in Spanish vessels. Over $\frac{1}{3}$ is taken by the United States, and about $\frac{1}{4}$ by England. Despite all restrictions, $\frac{1}{3}$ of the whole commerce is with the United States. According to U. S. treasury reports, the balance of trade against the latter amounted, from 1851 to 1856 inclusive, to about $10,000,000 yearly, and in 1857 was over $30,000,000.—The railroads, amounting in all in 1857 to 397 miles, have done much in maintaining and increasing domestic and foreign trade. The first was opened in 1837 from Havana to Bejucal, 15 m., in the next year to Güines, 45 m., and by subsequent extensions now forms the principal trunk line in the island. The common roads throughout Cuba are very bad, and in the rainy season frequently impassable. Several improved roads, having toll gates, lead

out from Havana. The electric telegraph was introduced in 1852, and its lines now extend between the principal cities and towns. The coast shipping has remarkably increased since 1840. Steamboats ply regularly from the various ports of the island to each other and to foreign ports. The circulating medium is chiefly metallic, and was exclusively so until Jan. 1857, when the first issue of paper currency was made by the Spanish bank, which was formally organized in Feb. 1856, having a capital of $3,000,000.—Education has made great progress since 1842. In Havana there are several institutions of a collegiate rank, with a number of seminaries, and in other cities there are advanced schools. The number of newspapers and periodicals published in Cuba in 1857 was: at Havana 21, Matanzas 3, Cardenas 1, Cienfuegos 2, Villa Clara 2, Remedios 1, Santo Espiritu 2, Trinidad 1, Puerto Principe 1, Santiago de Cuba 5, Bayamo 1; total 40.—In its government, Cuba is subject in all branches of the administration to one authority, the representative of the Spanish crown, who is appointed by and accountable only to the home government. He is president of the royal court of judicature (*real audiencia*), superior civil governor, captain-general, superior commandant of marine, superintendent of the treasury, viceregal patron and viceregal protector of public instruction. Of the 6 principal branches of administration, the political and military are particularly under his charge, and the judicial, financial, naval, and ecclesiastical branches are mainly directed by their respective chiefs of high rank. Each division has its determinate territorial subdivisions. The ecclesiastical administration is divided between 2 dioceses, the archbishopric of Santiago de Cuba and the bishopric of Havana, which are respectively superior one to the other in cases of appeal. The Roman Catholic is the only form of worship tolerated. The revenues are divided into maritime and inland, the first comprising customs and lighthouse dues, ship visits, &c., and the second various. The following is a synopsis of the receipts of the treasury for 2 years:

Sources.	1856.	1857.	Increase.
Customs.....	$9,739,524 12	$10 495,858 37	$757,334 25
Taxes.....	4,022,056 71	5,186,289 72	1,164,233 01
Lottery.....	1,329,107 37	1,681,410 12	352,302 75
Total.....	$15.090,688 20	$17,363,558 21	$2.273,870 01

The principal items composing the receipts from customs in 1857 were: duties on imports, $7,074,207; duties on exports, $1,777,868; tonnage dues, $931,869; registry fees (of cargoes, visits, &c.), $159,131. One-half of the revenue is absorbed in supporting the military department of the government. The regular armed force consists on an average of 20,000 men, and is kept in a high state of discipline, and in complete equipment. Nearly the whole of the troops are composed of soldiers from Spain, whose period of service in Cuba is generally limited to 3 years. The organized Cuban militia numbers between 3,000 and 4,000. The squadron on service usually consists of 26 vessels, with 200 guns, and over 3,000 men.—Cuba was the first land of importance discovered by Columbus in his first voyage. After touching at the islands which he called San Salvador, St. Mary of the Conception, Fernandina, and Isabella, his ships entered the mouth of a large river into a country called by the natives Cuba, and which he named Juana, in honor of Prince John, the son of his royal patrons. After the death of Ferdinand it was called Fernandina, and still later Santiago, in honor of the patron saint of Spain, and again Ave Maria, in honor of the Virgin. The large river which Columbus entered is supposed to be the outlet of the harbor of Nuevitas, on the N. shore; at ebb tide a swift current flows out like that of a river; and the breadth of the island at this point is reconcilable with the statement of some of his people having penetrated 60 miles into the interior, and yet bringing back no account of discovering the sea on the other side. From this point he explored the coast to the E. extremity of the island, seeking for gold, and then passed around to Hayti. The discovery of Cuba was on Oct. 28, 1492, and his arrival at Hayti was on Dec. 6. The first settlement of Europeans in Cuba was made by an expedition of 300 men under Diego Velasquez, fitted out by Diego, the son of Columbus, in 1511. They founded Baracoa near the E. end of the island, and in 1514 Santiago, which was made the capital, and Trinidad on the S. coast. A place on the S. coast in the partido of Güines was settled in 1515, and called San Cristoval de la Havana. The name was transferred to the present capital in 1519. The Spaniards found the aborigines of the island an effeminate and inoffensive people, entirely unable to resist the invaders of their country, or endure the severities imposed upon them. Velasquez encouraged settlers by grants of lands and of Indian slaves, and engaged them in agricultural pursuits, and especially in the cultivation of the sugar crop, for which the soil and climate seemed to be admirably adapted, and which was also introduced into Hayti. As early as 1534 the officials, as cited by Sagra in the appendix to his *Historia fisica, politica, y natural*, applied to the emperor for "7,000 negroes, that they might become inured to labor before the Indians ceased to exist." Gomara, the historian, states that there was not one Indian left after 1553. They were destroyed by cruel treatment and unaccustomed labor, were swept off by small pox, committed suicide in great numbers, and many fled in their boats to Florida. With the extinction of the Indians the agriculture of the island declined, and it became mainly a pastoral country. The extensive plains bordering the coast afforded a fine range for cattle, and their hides furnished the chief product for exportation, even to the 18th century. Bees were introduced from Florida, and wax and tobacco also became

at last of more importance than hides; and these are still important products, though now surpassed by sugar and coffee. The port of Havana soon came to be regarded as the principal stronghold of the island. The settlement there was twice destroyed by the French in the 16th century—once in 1538, and again in 1554, after it had been reëstablished and fortified by Fernando de Soto. New forts were added in the same century, and these form a part of the defences now known as the Moro castle and the Punta. The wall around the city was commenced in 1665. In 1762 Havana fell into the hands of the English, who retained it about a year, when they gave it up in exchange for Florida. Up to this time the population of Cuba had increased but slowly, and the productions were very limited. According to an official document, published at Havana in 1811, and based on the records of the custom house, the total import of slaves prior to 1763 had amounted to but 60,000. In 1765 the island contained about half that number of negro slaves, with as many free colored persons, mostly mulattoes. Its trade, hitherto limited to Cadiz, was, except the import of slaves, now made free to all Spaniards from the 9 principal ports of Spain. But at this time it was so small as scarcely to employ 6 vessels. From 1763 to 1789 the import of slaves was about 1,000 a year, which hardly kept up the number. In 1789 the Spanish slave code was promulgated, and the slave trade, hitherto a monopoly, made free. Under the administration of Las Casas as captain-general, which commenced in 1790, Cuba made rapid progress in commercial prosperity, and in its public improvements. In the 31 years from 1789 to 1820, the import of slaves amounted to 225,000, an average of 7,500, and from 1810 to 1820 it was 11,500 a year. The decline of Hayti opened a market for Cuban sugars, the production of which rapidly increased. In 1809 and 1811 the island was partially opened to foreign vessels. With the reëstablishment of peace in Europe the demands for Cuban products revived, and notwithstanding the treaty of 1820, by which Spain agreed with England to put a stop to the slave trade, the importation of slaves was continued on a larger scale than ever. In the 25 years from 1817 to 1842, it was estimated by the English commissioners to have reached the number of 335,000, or upward of 13,000 a year. This continued violation of treaty obligations led Great Britain to propose in 1841, as the only means of putting a stop to it, the establishment of a mixed tribunal in the island, with power to give liberty to all negroes who had been imported contrary to law. This proposition excited the greatest alarm among the Cuban proprietors, and the Spanish government, in consequence, began to take steps to stop the traffic. In 1845, for the first time, a law was enacted making the introduction of slaves a criminal offence. From these and other causes, during the 10 years from 1842 to 1852, the importation was considerably reduced, amounting in the whole to about 55,000. In the years 1845 to 1847, by the energy of Governor-general Concha, it was brought almost to an end. But the increased consumption of sugar in Great Britain, in consequence of the reduction of duty, and the placing of foreign and British sugars on the same level, gave a new stimulus to the traffic. The efforts of the Spanish officials for its suppression were relaxed, and it still continues to be prosecuted, as already stated, mainly, as the British allege, in vessels purchased and fitted out in the United States, and which retain the American flag till they are ready to leave the African coast. With the renewal of the slave trade the British renewed their remonstrances, and their former proposition for liberating the illegally imported negroes. This subject was much pressed from 1850 to 1853, but seems since then to have been abandoned. Some remarkable changes were made in 1854 by the Spanish administration of the island, in relation to the free blacks, who form so considerable a part of the population. The ecclesiastical rule which forbids the celebration of marriages between blacks and whites was abrogated, and a militia composed of free blacks and mulattoes, to the exclusion of the whites, was directed to be organized throughout the island, and was put on an equal footing in regard to privileges with the regular army. At the same time the white inhabitants were disarmed. Both these measures, which are still maintained, were adopted, in part at least, as a means of strengthening the government against the discontent of the white planters, and the danger of fillibuster expeditions from the United States, of which at this time serious apprehensions existed. From the moment the United States acquired Florida, the government at Washington began to take a deep interest in the future of Cuba. Fears were entertained lest the island might fall into the hands of the English or French, and both Spain and those nations were informed that the United States would never consent to that arrangement. They were willing that Cuba should remain a colony of Spain, but would never allow it to pass into other hands. Spain was repeatedly urged by the American government to make peace with the Spanish American republics, lest they should invade Cuba, and bring about not merely a political revolution, but a change in its social system. The claim of the English to make the slave trade suppression treaty an occasion for interfering in the domestic concerns of the island became a new occasion of jealousy. But a proposition made in 1825 on the part of Spain, that in consideration of certain commercial concessions the United States should guarantee to her the possession of Cuba, was declined by Mr. Clay, then secretary of state, on the ground that entanglements of this sort were contrary to the established policy of the United States. In 1848 President Polk authorized the American minister at Madrid to offer to purchase Cuba, and to pay $100,000,000 for it; but this proposition was rejected by Spain in the most peremptory

manner. It was not till after this that the attention of the American people, as distinct from the government, was first attracted to this question of the annexation of Cuba. The occasion was the resort to the United States in 1849 of Lopez, and other Cubans, who, in consequence of some attempted revolutionary movements, had been obliged to fly the island. They represented the creole population as greatly dissatisfied with the Spanish rule, and ready for revolt, and annexation to the United States. Recruits were collected for a descent upon the island. The first attempt was defeated by the vigilance of the government of the United States; but in Aug. 1851, Lopez sailed from New Orleans in a steamer with 500 men on board, of whom a considerable part were Americans. They effected a landing, but made no impression, and were soon taken prisoners. Lopez was garroted at Havana, Aug. 16; some of his comrades were shot, but the majority were transported and afterward pardoned. The sympathy which these movements, and other subsequent projects of the same sort, had found in the United States, and the refusal of President Fillmore in 1852 to join with France and Great Britain in a treaty guaranteeing to Spain the possession of Cuba, made the Spanish government still more alert in guarding against revolution, and especially against the entrance into the island of revolutionists from the United States. This led to occasional collisions with American citizens; and the firing on the American steamer Black Warrior by a Spanish vessel of war, during the administration of President Pierce, seemed at one moment to threaten hostilities. The disposition on the part of the creole planters to throw off the Spanish rule, or at least any overt exhibition of it, subsided after the failure of Lopez, but the idea of the acquisition of Cuba is still entertained in the United States. In Aug. 1854, Messrs. Buchanan, Mason, and Soulé, U. S. ministers at London, Paris, and Madrid, held a conference on the subject of Cuba, at Ostend and Aix la Chapelle, and drew up a statement of their conclusions, popularly known as the Ostend manifesto. In this document they argued that the island ought to belong to the United States, and that Spain would find its sale to be highly advantageous; and finally, that in certain contingencies, such as the emancipation of the slaves by the Spanish government, the United States ought to possess themselves of the island by force. A proposition was strongly urged in the senate of the United States in the session of 1858–'9 to place $30,000,000 in the hands of the president with a view to the acquisition of the island; but after debate, it was withdrawn by its author, Mr. Slidell of Louisiana.

CUBE (Gr. κυβος, a die), in geometry, a solid body terminated by 6 square equal faces, occupying among bodies a place analogous to that of the square among surfaces. The problem of the duplication of the cube, or of constructing a cube of twice the volume of a given cube, is celebrated in the history of science. It occupied geometers in the time of Plato; and it was a Greek tradition that once during a pestilence the priestess at Delos had responded that in order to appease the gods her altar must be doubled. The altar was cubical, and a new one was therefore built whose sides were of twice the dimensions of the old one. The priestess responded that her command had been wrongly interpreted, and from that time the geometrical duplication of cubic figures was a constant problem, like the quadrature of the circle. The cubature of solids, or the reduction of any body to a cubic form of equal volume, is performed by first reducing the given volume to one of the geometrical figures the law of whose curvature is known, as the parallelopipedon, cylinder, cone, or sphere.—In arithmetic and algebra, a cube is a number formed by raising another number to its third power; thus, 27 is the cube of 3, being equal to $3\times3\times3$. The number which is thus multiplied to make a cube is called the cube root.

CUBEBS, berries of the *cubeba officinalis*, a climbing perennial plant of the natural order *piperaceæ*, which is found wild in Java and other parts of the East Indies. It is supposed they were first brought into Europe by the Arabians; and in former times it appears they served the purpose of black pepper, their aromatic, warming, and pungent properties rendering them an agreeable condiment. In India they have long been used as a medicine in disorders of the digestive organs, on account of their carminative properties, and in diseases of the urinary organs for their stimulating effect. It is imported in the dried berries, which are of the size of small peas, and of a dark brown color. The volatile oil they contain is thus better retained than if the berries were pulverized, as they require to be to prepare the medicine. Beside the volatile oil they also contain the peculiar principle cubebin, a white, inodorous, and tasteless substance, not volatilizable by heat, and almost insoluble in water. The oil, having the medicinal properties, is often used instead of the powdered cubebs. It is obtained sometimes to the amount of 7 per cent. by grinding the cubebs, and distilling with water.

CUBIÈRES, Amédée Louis Despans, a French general, born in Paris, March 4, 1786, died Aug. 6, 1853, took an active part in the wars of Napoleon, was commander of the French army at Ancona from 1832 to 1836, created a peer of France in 1839, appointed minister of war in 1839 and again in 1840. Afterward he was implicated in a charge of having bribed M. Teste, the minister of public works in 1842, for the purpose of obtaining a grant for the working of salt mines. Tried in 1847, he was found guilty, sentenced to civil degradation, and to pay a fine of 10,000 francs. In 1852, however, he was reinstated in his position.

CUBIT, an ancient measure, taken from the human arm as measured from the elbow to the end of the middle finger. Its length was in practice somewhat indefinite, and varied among

different nations. According to Dr. Arbuthnot, the Roman cubit was $17\frac{4}{10}$ inches, and the Scripture cubit less than 22 inches.

CUBITT, Thomas, an English architect and builder, born at Buxton, Norfolk, in 1788, died at Denbies, Surrey, Dec. 26, 1855, was the son of a laborer, went to the West Indies as a ship carpenter, and on his return set up in business for himself. In 1823 he took on building leases some suburban property of the duke of Bedford, and finally laid out and built that part of the west end of London known as Belgravia. He afterward laid out and built Kemp Town, Brighton, and the queen's residence of Osborne, in the isle of Wight. He took a hearty interest in all the plans for social and sanitary improvement, and set an example among his own workmen by promoting benefit societies and associations for mutual improvement.

CUBITT, Sir William, an English civil engineer, born in Norfolk in 1785, was brought up as a joiner, adopted the trade of a millwright, and invented self-regulating sails for windmills. About 1808 he entered a machinist's establishment at Ipswich, and was so successful there that he determined on settling in London, which he did in 1826. At the commencement of the railway movement he became engineer of the London and Dover line. He was knighted in 1851 for his services as one of the superintending committee of the great exhibition.

CUCKING STOOL, or Tumbrel, a machine formerly used in England for the punishment of scolding women and dishonest brewers and bakers. It consisted of a stool or chair attached to a long pole, mounted in such a manner that the chair with the criminal in it might be swung over a pond and submerged.

CUCKOO (*cuculus*, Linn.), a genus of birds of the order *scansores*, and family *cuculidæ*, inhabiting the temperate and warmer regions of the old world; the cuckoos of America belong to another subfamily of the same order. The true cuckoos, as exemplified in the genus *cuculus*, have the bill broad, rather depressed at the base, curved, gradually compressed to the acute tip; the nostrils are round and exposed; the wings are long and pointed, the 3d quill being the longest; the tail is long and graduated, or even, and the outer feather of each side is shorter than the others; the tarsi are very short and partially feathered; the toes, 2 before and 2 behind, are unequal, the outer anterior one being the longest, and united to the inner at the base. More than 40 species of this genus are well determined, of which the best known and most interesting is the common European cuckoo (*C. canorus*, Linn.). In this bird the corners of the mouth and eyelids, and the inside of the mouth, are of an orange color; the plumage of the head, neck, breast, and upper parts, is a deep bluish gray; the under parts and the axillary feathers are white with distinct black bars; the quills are blackish gray, the inner webs with transverse white bars; the tail is darker, approaching to black at the end, and often with a green gloss, tipped with white, and each feather marked along the shaft with triangular white spots, which, meeting similar spots on the outer feathers, give an almost barred appearance to the tail; the feet are gamboge yellow, and the bill black. The length of the bird is 14 inches, and the extent of wings 25 inches. The young birds are of a brown tint, with reddish-brown bars and white markings, the white of the under parts being barred with black. The female very closely resembles the male. The cuckoo is associated with the return of sunny skies and the renewal of vegetation, and is a most welcome "messenger of spring;" it arrives from southern Europe in Great Britain in April, and generally departs in August. It is very generally distributed over Europe, decreasing in numbers toward the north; according to Temminck, it extends its migrations to northern Africa. The most singular habit of the cuckoo is that it deposits its eggs in the nests of other birds, leaving the care of the young entirely to the foster parents thus selected; the latter adopt the young cuckoo as their own, often to the destruction of their proper offspring, which are thrust out of the nest by the usurping stranger. The reason of this departure from the usual habit of birds is not well ascertained; it is common in the genus *cuculus*, and is also practised by our cowpen bird (*molothrus pecoris*, Gmel.). The cuckoo selects the nest of a bird smaller than itself, and of a great variety of species, as the warblers, sparrows, finches, and larks, and in it deposits a single egg, very small compared to the size of the bird; it is believed by Montague and others that the female has the power of retaining the egg in the oviduct until she can find a nest suitable for its reception; she lays several in the course of the season. The young cuckoo is said to eject its companions from the nest by lifting them out on its shoulders; from this habit has arisen the German saying, "as ungrateful as a cuckoo." The well-known notes of this bird, as heard in the breeding season, resemble very much its name; the song is loud and joyful, and confined to the males, and is silent before their departure. Its food consists of the larvæ of insects and caterpillars; before swallowing the latter it is in the habit of cutting off the hinder end and freeing the body from the intestinal canal by repeated jerks with its sharp bill. The males are more numerous than the females, and are bold and fierce, and rarely kept as pets. In autumn they are fat and esteemed as an article of food; the ancients were very partial to them, and their flesh was supposed to have valuable medicinal properties. — The American cuckoos belong to the subfamily *coccyzinæ*, or ground cuckoos, and to the genus *coccyzus*. In this genus the bill is long and rather slender, and curved; the nostrils are oval; the 3d and 4th quills are the longest; the tail is long, broad, and rounded on the sides; the tarsi are shorter than the middle toe, and naked; the toes are

unequal, and the claws long, compressed, curved, and acute. There are 3 species described, belonging to North and Central America, though a few stragglers have occasionally been seen in Europe; they are shy birds, frequenting the dense woods and solitary swamps. I. The yellow-billed cuckoo (*C. Americanus*, Linn.) has a length of 12½ inches, and an extent of wings of 16 inches; the bill is 1 inch long, for the most part of a yellow color; the iris is hazel; the general color of the upper parts, with the wing coverts and two middle tail feathers, is light greenish brown, deeper anteriorly; tail feathers, excepting the two middle ones, black, with a broad white space at the end of the 3 outermost, the 4th white on the outer web; the primaries have their inner webs brownish orange; the under parts are grayish white. The female differs little from the male. Its notes resemble the word "cow, cow," repeated several times with increasing rapidity; hence one of its names, cow bird; it is also called rain crow and coucou. It is found in all parts of the United States, though nowhere in abundance. Its food consists of caterpillars, insects, wood snails, berries (especially the mulberry), and grapes; it sucks the eggs of other birds, and itself falls a victim to many species of hawks. Its flight is rapid, but the gait on the ground is very awkward; its favorite retreat is the thickest foliage. Unlike the European cuckoo, this bird builds its nest and rears its young in the usual manner; the flat nest is very simply composed of a few dry sticks and grass, on a horizontal branch of a low tree; the eggs are 4 or 5, of a bright green color. It migrates southward, generally beyond the limits of the United States, as cold weather approaches, in flocks and high in the air; single birds begin to enter our borders early in March, arriving as far as New York early in May. II. The black-billed cuckoo (*C. erythrophthalmus*, Wils.) is a little smaller than the preceding species, from which it is also distinguished by its dark-colored bill, a bare scarlet space around the eyes, and the browner tint of the under parts. The present species does not frequent the interior of deep woods, but prefers the edges of forests on the border of the sea and lakes. It feeds principally on shellfish and aquatic larvæ and insects; it is very fond of the small frogs so numerous after summer showers. Its flight is more rapid than that of the yellow-billed species; in other respects, as in its migrations, general habits, and manner of constructing its nest, it much resembles the last named bird, and has frequently been mistaken for it. The eggs are of a greenish blue color. III. The mangrove cuckoo (*C. minor*, Gmel.) is 12 inches long and 15 inches in extent of wings; the general color of the upper part is light greenish brown, the head tinged with gray; primaries umber-brown; tail feathers, excepting the two middle ones, brownish black with white tips; the under parts brownish orange; in other characters it much resembles the yellow-billed cuckoo. Its habits are the same as those of the other species of the genus; it feeds on insects, fruits, and the eggs of other birds; it is vigilant and shy, not extending its migrations northward beyond Florida; it prefers the mangrove-covered islands, building its nest amid their dark foliage. The flight is rapid and elevated during the migrations. The female is paler than the male, especially on the lower surface, which is grayish.

CUCUMBER (*cucumis*, Linn.), a vegetable fruit in a genus of cucurbitaceous plants, to which likewise belongs the melon, having annual fibrous roots, brittle climbing stems, rough, unequally divided leaves, and tendrils formed of the abortive stipules. The cucumber is thus a sort of gourd represented in its real type, better perhaps, by the colocynth gourd—a bitter, powerfully purgative species, known as *C.* (*citrullus*) *colocynthis* (Persoon). In position these plants are to be placed between the myrtles and passion flowers—to the latter, indeed, so closely allied that they scarcely differ except in some particulars of structure, the habit of both being the same. It has been conjectured that long continued cultivation has done much toward ameliorating the bitter and dangerous properties of this group of plants; and several allied kinds in their wild state, it is known, have proved deleterious. All the numerous cultivated varieties of the melon and cucumber are delicious or wholesome fruits. The writer has raised cucumbers from seeds received from the East Indies, which looked like the common cucumber, only smaller; they were so intensely bitter as to be worthless; and the stem end of the better sorts of the garden cucumber is frequently bitter and disagreeable. The drastic property is strong in many of the allied genera from Brazil, and in the spirting cucumber it exists in concentrated virulence. The common cucumber (*C. sativus*, Linn.) is too well known for any lengthened description. It is a native of tropical Asia. In cultivation, the cucumber requires a deep and rich soil, an abundance of moisture, and continued heat. If planted sufficiently late to escape the frosts, it will grow with scarcely any care; it is subject, however, to the depredations of numerous insect foes. The best way to prevent these is to cover the young plants with boxes having gauze tops, which should be kept over them until the foliage is large and abundant. The cucumber loves to support itself by its tendrils in an upright position upon pieces of brush wood, and the cleanest and best fruit is thus obtained. This will be found to be a good practice, too, where there is but little room for a horizontal growth upon the ground. As an early vegetable, scarcely any other plant can be so successfully forced in the hot-bed; but the best sorts should be selected for the purpose. Great skill oftentimes is requisite in the management, to keep the plants vigorous and healthy, and to sustain an unchecked growth. Beside affording in its fruits a palatable and cooling salad, the cucumber has been used in medicine, for pectoral complaints

and as a febrifuge. Its expressed juice is employed as a cosmetic; and it is said to give a pleasant suppleness to the skin. It enters into the composition of some of the French pomades; and the pulp boiled for a long time in lard makes a soothing and cooling ointment, of repute among domestic curatives.

CUCUTA, Valleys of, a district of New Granada, in the province of Pamplona, about 90 m. in circumference; pop. about 30,000. The surface consists of a succession of hills and valleys, the former sterile and the latter uncommonly luxuriant. At Cucuta, or Rosario de Cucuta, the capital of this district, was held the first general congress of Colombia.

CUDBEAR, the name given by the Scotch to a dyestuff prepared from different genera of lichens. It is obtained in the form of a powder of a lake or red color, and is the same substance which, prepared by the English in the form of a violet-colored paste or a purple liquid, is called archil; and also the same as the solid cakes manufactured by the Dutch and called litmus. It is used, like archil, for giving to woollens and silks a great variety of colors, but does not answer for cotton, having no affinity for its fibre.

CUDDALORE, a town of Hindostan, on the Coromandel coast, in the S. division of Arcot, 100 m. S. from Madras, on the estuary of the river Punnair. It was acquired by the East India company in 1681; was captured by the French in 1758, and retaken by Sir Eyre Coote in 1760. With the assistance of Hyder Ali the French took it again in 1782, and greatly strengthened its fortifications. The following year it was besieged by the British, but the declaration of peace put an end to the siege, and in 1801 they acquired the place by treaty.

CUDDAPAH, or Kirpa, a town of British India, capital of a district of the same name, in the presidency of Madras, 78 m. W. from Nellore. It is a military station, near one of the lines of the Madras railway, on the river Cuddapah or Bogawunka, and was once the capital of an independent Patan state. It is famous for its diamond mines, on the Punnair river, 7 m. N. E. from the town, which have been worked with various success for several hundred years.

CUDWORTH, Ralph, an English divine and philosopher, born at Aller, in Somersetshire, in 1617, died at Cambridge in 1688. At the age of 13 he was entered at Emmanuel college, Cambridge, in which he afterward became fellow and tutor. In 1639 he took the degree of master of arts, in 1644 that of bachelor of divinity, and in 1645 was appointed regius professor of Hebrew, in which office he continued during 30 years. In 1641 he was presented to the rectory of North Cadbury, and in the next year published a sermon on the true nature of the Lord's supper, which attracted the notice of several learned writers. After a short absence from Cambridge, caused by pecuniary embarrassments, he returned in 1654, when he was elected master of Christ's college. His subsequent preferments were a vicarage of Ashwell in 1662, and a prebend of Gloucester in 1678. In performing the duties of his professorship he devoted much attention to Hebrew literature and antiquities, and he was one of the persons consulted by a committee of parliament concerning a new translation of the Bible. In 1678 he published his great work, which had been written several years before, entitled the "True Intellectual System of the Universe," the epithet "intellectual" being intended to contrast it with any physical theory, as the Ptolemaic or Copernican. The design of the work was to establish human liberty against the fatalists, and according to the scope of the author it was to consist of 3 parts; the first being a refutation of atheism and atheistic fatalists; the second, of those who admitted a Deity, yet acting necessarily and without moral perfections; and the third, of those who granted the moral attributes of God, but affirmed that human actions are governed by necessary laws ordained by him. Only the first part of this scheme was completed, and the "Intellectual System" consists of a most erudite argument against atheistic fate. To account for the operation of physical laws without the continued agency of Deity he devised the theory of a plastic nature, which he treats as a real being, giving it "a drowsy unawakened cogitation," and which he makes the immediate and obedient instrument in the execution of divine purposes. He also reviewed the systems of ancient speculation in order to show that a belief in one sovereign and omnipotent God underlay the polytheistic views of the pagan nations. Dr. Cudworth left several large ethical and theological works, which still remain in manuscript in the British museum. His "Treatise concerning Eternal and Immutable Morality," was first published by Bishop Chandler in 1731. Its design is to prove that moral differences of right and wrong are antecedent to any divine law, and it was probably a partial accomplishment of the second division of his proposed "Intellectual System." Cudworth was one of the most eminent of several Cambridge divines who were termed Latitudinarians; and the clear and fearless statements which he made of the arguments of his opponents caused him to be accused by some of his contemporaries of heterodoxy, and of raising "so strong objections that he did not answer them." Bishop Burnet speaks of him as "a great man in all parts of learning, divine and human; an honor to Emmanuel college where he was educated, to Christ's college where he afterward presided, to the whole university of Cambridge which he adorned, and to the church and age in which he lived." The "Intellectual System" was republished in London in 1743, in 1820, and in 1845; the last edition is in 3 vols., and contains translations of the valuable notes of Dr. Mosheim. All of his printed works appeared at Andover, Mass., in 1837.

CUENCA, a S. province of New Castile in Spain, between lat. 39° 20′ and 40′ 47′ N., long. 1° 5′ and 3° W.; bounded N. by Guadalajara,

E. by Teruel and Valencia, S. by Albacete, W. by Ciudad Real, Toledo, and Madrid; area, about 12,000 sq. m.; pop. in 1857, 243,260. It is one of the most mountainous provinces of Spain. The products are timber, excellent honey, several minerals, oil, fruit, hemp, flax, and grain, and wine in the S. W. part. The principal exports are saffron and a superior quality of wool. Only one sixth part of the soil is cultivated, and most of the rest is used for pasturage. There are several medicinal springs in the province. The woollen industry, for which it was renowned in former times, has much declined. It is divided into 9 districts and 318 parishes.—The capital, CUENCA, pop. about 7,000, 85 m. from Madrid, is one of the most picturesque towns of Spain, about 3,400 feet above sea level, between the heights of San Cristobal and Socorro, at the confluence of the Huescar and Jucar. Once celebrated alike for arts, literature, and industry, it is now remarkable only for its Moorish aspect, for its cathedral, and for its scenery. The beautiful forests, called *los pinares de Cuenca*, adjoin the town, as well as many lakes and streams containing trout, while the mountains abound in curious plants and geological objects. Near the cathedral is the bishop's palace. Beside a number of churches, the city contains 2 hospitals, 3 colleges, and a clerical seminary. The most remarkable of the bridges of Cuenca is that of San Pablo over the Huescar. The town is surrounded by high old walls, and has woollen factories, paper mills, and establishments for washing wool.

CUENCA, or RAMBAE, a city of the republic of Ecuador, and capital of a canton and province of the same name, in the district of Assuay; pop. about 25,000. It is built on a beautiful plain 8,640 feet above the sea, near the river Matadero, and about 4 m. from the Machangara, from which streams irrigating canals lead toward the city. It has broad and regular streets, contains a Jesuits' college, a cathedral, 8 churches, the governor's residence, and a well arranged prison, has manufactories of good pottery, and is regarded as one of the finest cities of the republic. Its private houses, however, are mostly low and mean-looking. Its trade is chiefly in grain, hats, bark, and dairy produce. In the neighborhood is the hill of Tarqui, which was fixed upon by La Condamine, Bouguer, and Godin, for establishing their meridian line in 1742; and on the plain which lies around it was fought, in 1828, the battle of Tarqui, between the armies of Colombia and Peru.—The province of Cuenca is mountainous, well watered, and fruitful. It produces grain, sugar, cotton, bark, and cochineal, has manufactories of tapestry, drugget, and cotton, and contains gold, silver, copper, mercury, and sulphur, but the mines are not worked. It is divided into the 3 cantons of Azogues, Cuenca, and Gualaceo.

CUEVA, JUAN DE LA, a Spanish poet, born in Seville about 1550, died about 1608. He wrote several dramas on national subjects; an epic (*La conquista de la Betica*, printed in 1603) on the conquest of Seville by St. Ferdinand—an unsuccessful imitation of Tasso's "Jerusalem Delivered;" and over 100 ballads (*Coro Febeo de romances historiales*, Seville, 1587–'88), mostly taken from the histories of Greece and Rome, and only 4 or 5 from that of Spain. His fame rests more particularly upon his having been the first Spaniard to attempt didactic poetry; his poem, entitled *Egemplar poetico*, which he wrote in 1605, but which was first printed only in 1774 in the 8th vol. of the *Parnaso Español*, constituting the earliest and most original effort of the kind in Spanish.

CUFFEE, PAUL, a philanthropic negro sea captain, born on one of the Elizabeth isles, near New Bedford, Mass., in 1759, died Sept. 7, 1818. His father was a native of Africa, and once a slave; his mother was of Indian extraction. Endowed with a commanding presence, strong common sense, and untiring industry and enterprise, he accumulated a handsome fortune in seafaring pursuits, and for many years commanded his own vessel, having a crew composed entirely of negroes, and visiting many American and foreign ports. He was an esteemed member of the society of Friends. It is related of him that on one occasion, when the custom house officer of Norfolk, Va., refused him a clearance on the ground that he was a negro, he proceeded at once to Washington to submit his case to President Madison, with whom he was well acquainted. "James," said he to the president, "thy customs collector at Norfolk refuses me my clearance; I wish an order from thee, which shall compel him to give it me." President Madison inquired into the circumstances, and wrote the required order, by which he obtained his clearance without further delay. In the latter part of his life Captain Cuffee encouraged the emigration of the free people of color in this country to Sierra Leone. He corresponded with prominent friends of that enterprise in Great Britain and Africa, and in 1811 visited the colony in his own vessel to determine for himself its advantages. In 1815 he carried out to Sierra Leone 38 colored persons as emigrants, 30 of them entirely at his own expense, and on his arrival there furnished them with the means of subsistence, spending in this enterprise nearly $4,000. He was anxious to carry other companies of emigrants; but while waiting for the permission of the British government, American vessels being at that time excluded from the trade of the British colonies, he was seized with the illness which terminated his life.—Rev. PAUL, a native Indian preacher to the Shinnecock tribe of Indians on Long island, born in 1757, died March 7, 1812. He was for 13 years in the employ of the New York missionary society, and was regarded as an able preacher. He was a successor of the celebrated Rev. Samson Occom and the Rev. Peter John.

CUFIC INSCRIPTIONS AND COINS, so called because they bear the *Kufi* or Cufic writing, a character named from Cufah, a city

of Irak-Arabi, on the Nahr-Cufah or Euphrates, in the pashalic of Bagdad. Cufah was built by Sa'ad, in A. D. 639, under Omar, the 2d caliph, after his capture of Modain, the capital of Sassanidic Persia. It was the residence of Ali, the 4th caliph, and, a century later, of Abul Abbas, the founder of the Abbasside dynasty; it also possessed a celebrated school. After the foundation of Bagdad by Abu Giaffar Al Mansoor, the 2d Abbasside, Cufah was neglected and began to decay. At the time of Mohammed the Arabs of Hedjaz used a writing similar to the Neskhi, which may be seen in some papyri in the *Mémoires* of the French academy and in the "Asiatic Journal." According to Arabic tradition, writing at that time was newly invented and in little use. Whether the Arabs of Yemen, Irak, Mesopotamia, and central Arabia, had derived their writing, much earlier, from the Phœnician, or Palmyrean, or Sassanidic, is not ascertained. The *Kiufi*, however, is probably derived from the Syrian *estranghelo* (στρογγυλος, round). It is coarse, stiff, angular, and not so distinct as the modes of writing derived from it. It consists of 18 forms of letters, 8 of which, by being marked with diacritic points, represent 10 sounds of the modern Arabic writing—these we include in parentheses—namely: *a*, *b* (*t*, *th*), the English *j* (*h*, *kh*), *d* (*dh*, the English *th*, as in this), *r* (*z*), *s* (*sh*), *ss* (*dz*, Spanish *c* in *celebre*), *t*, *ain* (*ghain*, both peculiar gutturals, or rather faucals), *f*, *k* harsh, *k* soft, *l*, *m*, *n*, *h* (or merely the *spiritus lenis*'), *u*, *i* or *y* (German *i*, *j*). In manuscripts, the vowels are sometimes marked with red or yellow points. This writing was used in manuscripts for about 3 centuries; and on coins, sepulchral monuments, in titles of books, for about 7 centuries after Mohammed. Even now the writing of the African Arabs and Moors resembles the Kiufi; while the Orientals, who are very fond of flowing, elegant, slender letters, use, especially for copying, the Neskhi, whose introduction is attributed to Ibn Mokla, in the 4th century of the Hegira. There are also many other modifications in Persian, Turkish, Hindostanee, and Malay chirographs. —Cufic characters are found on the coins of almost all Mohammedan nations. The coins of the earlier rulers are mostly without an effigy, and ill-stamped; but the most celebrated ones show the face of the ruler, although this is anti-Mohammedan; and those of later times exhibit either a sign of the zodiac or stars, or the heraldic sign (*tamgna*) of the Turkish sovereigns. The inscriptions on the coins contain the name of the potentate by whom they are issued, the year of coinage, &c., and most frequently the phrase: "Coined in the name of Allah," either around or on the edge, and sometimes in 2 lines. The form is, on the whole, either Byzantine or Persian, in the style of Nushirvan or Chosroes I., and of Parvis or Chosroes II., both Sassanides. The dates of these coins extend from the Ommyiades, who ruled at Damascus from A. D. 661 to 750, down to the emirs of Ghizni, who bore sway in Turkestan, Persia, and India as late as the 12th century; most of them, however, belong to the 10th century of our era. Those of gold are called *dinar;* those of silver, *dirhem;* those of bronze or copper, *fuls*. Of some only halves and quarters of the original pieces now exist. The inscriptions are in several languages, some in two at once, some even in Arabic and Russian. They are found in Africa and Asia, from the Caspian and Euxine to the Baltic, in Pomerania, Brandenburg, &c., where they have been brought by commerce; and they are also met with in Spain, Naples, Sicily, &c. Glass medals are also found bearing Cufic inscriptions on either face or on both; they are about ¼ inch thick, and some have a higher margin on one side than the other. These probably belong to the Fatimite dynasty of Egypt; and some of them come down to the Mameluke sultans (1766). It is uncertain whether they were current as money.—See G. C. Adler, *Museum Borgianum* (Altona, 1780); Silvestre de Sacy, *Mémoires de l'académie Française;* Lindenberg, *Sur quelques médailles Coufiques et sur quelques MSS. Coufiques* (Copenhagen, 1830); Möller, *Orientalische Palāographie* (Gotha, 1844); and other treatises, especially those of Fraehn, published at Kasan and St. Petersburg.

CUIRASS, defensive armor for the body from the neck to the waist. It is generally made of well-hammered plate iron, and its name is probably derived from the French *cuir*, leather, of which material armor was very frequently composed in the early ages. The iron cuirass succeeded the hauberk or hacqueton in the reign of Edward III. The cuirass, under a variety of forms and names, was known to the ancient Greeks, Romans, Persians, and Egyptians. After long disuse it was adopted by Napoleon for his heavy cavalry, and his example has been followed by the English (who arm 3 regiments with it) and continental nations.

CUJAS (Cujacius), Jacques, a French jurisconsult, born in Toulouse in 1522, died in Bourges, Oct. 4, 1590. He was the son of a fuller, and was educated at the university of Toulouse; spent several years in acquiring a knowledge of law, and of the ancient languages, history, grammar, philosophy, mathematics, and even of poetry, and at the age of 25 commenced a course of instruction on the Institutes of Justinian. In 1554 the professorship of Roman law in the university of Toulouse became vacant, and Cujas, not being chosen to it, left Toulouse, and accepted a vacant chair at Cahors; but in 1555 he repaired to Bourges, then perhaps the chief seat of the study of civil law. The jealousy of rival professors having forced him to leave this place, he went to Paris, and published a portion of his works, including the *Observationum et Emendationum XXVIII libri*, which, in the hyperbolical language of the time, received the name of *opus incomparabile, opus divinum*. In 1557 he was invited to fill a chair in Valence, whence, in 1560, one of his rivals in Bourges being dead, he was recalled to that city, and there his

principal works were published. In 1566 he repaired to Turin to lecture in the university, and in 1567 returned to France, fixing his residence at Valence. In June, 1576, he finally returned to Bourges, which he never afterward quitted. The latter part of his life was clouded by domestic cares and by the distress of mind which the unhappy condition of his country created. After the assassination of Henry III., the league, who were powerful in Bourges, endeavored to extort from Cujas a written opinion in favor of the claims of Cardinal Bourbon to the succession. At considerable personal risk he opposed the demand, exclaiming: "It is not for me to corrupt the laws of my country." He died soon after, broken-hearted, it is supposed, at the evils which preyed upon France. The jurisconsults of Europe agree in considering him the greatest, as he was among the first of modern interpreters of the civil law. Beside the Institutes, Pandects, &c., of Justinian, he published, with explanations, a part of the Theodosian code, and the *Basilica*, a Greek version of the laws of Justinian, and commentaries on the *Consuetudines Feudorum*, and on some books of the Decretals. His "Observations and Corrections," extending not merely to books of law, but to a number of Greek and Latin authors, have been of great value to philologists. The edition of Fabrot (Paris, 10 vols. folio) was the first complete collection of his writings; but the reprints at Naples in 1757, and at Venice and Modena in 1758–'82, in 11 vols. folio, contain important additions. Cujas was not less distinguished as a teacher than as a writer.

CULDEES, a religious fraternity who at one time were spread over the greater part of Great Britain and Ireland. The origin of the name is uncertain, some deriving it from the Celtic *cylle*, a cell, and *dee*, house, and others from the Latin *cultor Dei*, worshipper of God. Their history has been raised to importance by certain modern writers, who claim that in the 2d or 3d century they were the priests of a Scottish Christian church which had no bishops, and resembled the Presbyterian organization. It is not known when the order became extinct.

CULLEN, Paul, an Irish Catholic prelate, archbishop of Dublin, born about 1805. He studied theology in Italy, received orders, and for 15 years held an office in the chancery of the Vatican which gave him direction of the ecclesiastical affairs of his native country. He was also for some time rector of the Irish college at Rome. On the death of Dr. Crolly, archbishop of Armagh, in 1849, the suffragan bishops failed to agree in nominating his successor, and Pius IX. therefore conferred this dignity upon Dr. Cullen, with the rank of primate of Ireland and apostolic delegate. He was consecrated Feb. 24, 1850, and soon became conspicuous by his hostility to the system of mixed education which prevailed in the Irish schools, and his support of the scheme for founding a Catholic university at Dublin. To further the latter object, in obedience to the instructions of the pope, he called a synod at Thurles, which took such measures that the university was soon established. In March, 1852, Dr. Cullen was transferred to the diocese of Dublin. He thus ceased to be primate, but his title of apostolic delegate was renewed for life, which places him at the head of the Irish clergy. A curious work against the Copernican system, maintaining on theological grounds that the earth is the immovable centre of the universe, has been attributed to him, it is said, without reason.

CULLEN, William, a Scottish physician, born in Hamilton, Lanarkshire, April 15, 1710, died near Edinburgh, Feb. 5, 1790. He studied medicine at the university of Glasgow, and at the same time served an apprenticeship to a surgeon apothecary of that place. At the age of 19 he procured the berth of surgeon on a merchant ship engaged in the West India trade, and in 1732 returned to Scotland and commenced his professional labors in the parish of Shotts. After several years of practice and study he entered into a partnership with William Hunter, afterward celebrated as a comparative anatomist, by the terms of which they were each to spend a winter alternately at some medical school, while the other remained in charge of the business in the country. In 1741 Hunter repaired to London for the purpose of study, and having with the consent of Cullen settled there, the partnership terminated. In 1745 Cullen took up his residence in Glasgow, and in the succeeding year commenced a course of lectures in the university on the theory and practice of medicine. In 1751 he became professor of medicine, and lectured on chemistry, materia medica, and botany, giving much attention to the application of chemistry to agriculture and the useful arts. In 1756 he removed to Edinburgh to assume the chair of chemistry. He continued to be connected with the university until his death, and for nearly 34 years lectured with great reputation on chemistry, materia medica, and the theory and practice of medicine. He also delivered several series of clinical lectures at the royal infirmary. He possessed in a rare degree the faculty of presenting an abstract subject in a clear and attractive light, and his lectures, which were nearly extemporaneous, seldom failed to excite the interest, and even the enthusiasm, of his pupils. As an illustration of this, it is stated that the class in materia medica, which under the former professor, Alston, a man of great learning, had not exceeded 8 or 10 in number, was at once increased by Cullen to over 100. His works are: "First Lines of the Practice of Physic," containing his system of the nature and cure of diseases, which superseded that of Boerhaave; "Institutions of Medicine;" *Synopsis Nosologiæ Methodicæ;* a "Treatise of the Materia Medica;" and some minor miscellaneous publications. The first of these was translated into several languages, and went through many editions. His clinical lectures were also published after

his death, probably from notes taken by one of his pupils.

CULLODEN HOUSE, a family seat in Inverness, Scotland, which gave its name to the battle that ended the career of the pretender in the rebellion of 1745. The English troops were led by the duke of Cumberland; the highlanders were commanded by Charles Edward in person. The prince's army was composed of highlanders; he was almost destitute of artillery, in which arm the enemy were very powerful. The wild, undisciplined courage of the highlanders was vainly opposed to the discipline and cannon of the regulars. After a desperate attack and great carnage on both sides, the English troops stood firm, and the highlanders, unsupported and unofficered, broke and fled in all directions. The battle was fought on Drummossie moor, April 16, 1746.

CULLOMA, or COLUMA, a post town of California, and formerly the capital of El Dorado co.; pop. in 1852, 2,000. It is situated on the south fork of American river, and on the road from Sacramento City to Nevada. In the vicinity are a number of saw mills, one of which, called Sutter's mill, is memorable as the spot where gold was first discovered in California.

CULM, or KULM (Polish, *Chelmno*), a district and city in the Prussian province of West Prussia, in a very fertile region. The city is situated on a branch of the Vistula; pop. 7,800. It was founded by the knights of the cross in 1230, and became the residence of a bishop. It was under Polish sovereignty from 1454 to 1772, when it was given to Prussia by the first division of Poland. The inhabitants, of German origin, had their chartered city rights, copied from those of Magdeburg, collected and revised as early as 1394, which was ever recognized in old Prussia under the name of *Culmer Handfeste*, or *Jus Culmense*.

CULM, in Bohemia. See KULM.

CULMINATION, the passage of a star over the meridian, that is, over the highest point of its diurnal path. Metaphorically the term is used of any thing attaining its highest state of development.

CULNA, a town in British India, in the district of Burdwan, lieutenant-governorship of Bengal, lat. 23° 14′ N., long. 88° 20′ E., pop. 60,000, on the right bank of the river Hoogly, 26 m. E. of the city of Burdwan, a station for steamers plying between Calcutta and the upper provinces, and long noted for its trade in rice, grain, silk, and cotton. It is the station of the Free church mission, and has an English school containing about 120 boys.—There is a town of the same name, lat 23° 13′, long. 89° 42′, in the district of Jessore.

CULPEPPER, a N. E. central co. of Va., bordered S. by Rapidan river, N. E. by the N. branch of the Rappahannock, drained in the N. part by Hazel river; area, 673 sq. m.; pop. in 1850, 12,282, of whom 6,683 were slaves. The surface is greatly diversified by hills and valleys, and the soil very productive. The Rappahannock and Hazel rivers are here navigable, the latter for small boats only. There are one or two mineral springs in the county, but they are yet very little known. Indian corn, wheat, oats, and wool are the staples. In 1850 the productions were 191,395 bushels of wheat, 359,670 of Indian corn, 62,599 of oats, and 45,444 lbs. of wool. There were 17 churches and 488 pupils attending public schools. A number of woollen factories and flour, grist, and saw mills were in operation during that year. Value of real estate in 1856, $3,068,610. The county was formed in 1748, and named from Lord Culpepper, governor of Virginia in 1681. Capital, Fairfax, or Culpepper Court House.

CULPEPPER, JOHN, an early surveyor-general and political leader of the provinces of North and South Carolina, was a refugee from the southern or Clarendon colony, and in 1678 was the head of an insurrection in the northern or Albemarle colony in favor of popular liberty. The navigation acts, by which excessive taxation was imposed on commerce, and an abridgment of political freedom by the "denial of a free election of an assembly," were the chief grievances. Under his direction, the people deposed the president and deputies of the proprietaries, seized the public funds, appointed new magistrates and judges, called a parliament, and took all the functions of government into their own hands. The insurgents, having completed their institutions, sent Culpepper to England to negotiate a compromise. He was indicted for high treason, but through the influence of Shaftesbury he was acquitted on the ground that no regular government had existed in Albemarle. He returned to Carolina, and in 1680 laid out the city of Charleston, reducing the paths, streets, and squares to comparative regularity, and enclosing the town site with a line of fortifications.

CULPEPPER, THOMAS, lord, governor of Virginia from 1680 to 1683, died in 1719. Under his administration an act was passed to encourage emigration by enabling the governor to naturalize any person by instrument under his seal; also an act of indemnity for all offences committed in the rebellion under Gov. Berkeley, and one to prevent the frequent meeting of slaves. He was one of the grantees of the territory of Virginia, and in the year 1669 purchased of his co-grantees their rights to the country lying between the Rappahannock and Potomac rivers.

CULTIVATOR, in England, an implement used after the plough, preparatory to planting; in the United States, an implement for the same purpose, and also for scarifying the earth between the rows of growing plants, and turning it either to or from them, as desired. In the former country all implements for the latter purpose are called horse hoes. The American classification originated in our early manufacturers so constructing their patterns that the same implement could be used for both purposes. Some leading manufacturers are now,

however, advertising gang cultivators, cultivators, and horse hoes; the office of the first being limited to that of the English cultivator, the second being for operation both before and after planting, and the third for the latter purpose only. But, as other manufacturers apply these terms almost indiscriminately, while the New York state agricultural society awarded a premium to an implement in 1854 as the best cultivator, and again to the same implement in 1856 as the best horse hoe, there seems to be, as yet, no distinctive adherence to names, and no proper uniformity of classification. Cultivators, in a general description, are combined modifications of the plough and harrow. In England they are usually made with rectangular frames, constructed on 3 or 4 wheels, and provided with a series of complex levers, by which they can be raised or lowered for greater or less penetration of the teeth or shares below the surface. They are made of two classes, called grubbers and scarifiers, or cultivators; the first class being for cleansing the earth of roots and weeds, and the second for dividing and pulverizing, without any particular overturning like that given by the plough. The teeth of the former may be compared to fork tines, and of the latter to bent coulters, with small double mouldboards. In the United states there seems, however, to be an increasing desire to have cultivators overturn as well as scarify the earth, and hence the introduction of the gang cultivator, as above classified. This implement consists of a line of small steel ploughs, attached to a beam which passes over the ground at such an angle to the line of draught that each plough turns over and pulverizes some 7 inches of earth from the land side of the preceding one. This beam is fastened to the draught beam, which is armed in front with a coulter, and behind with a double-share cultivator tooth, which serves to balance the implement as it does its work. American cultivators, for the double purpose above described, are either triangular or rectangular frames, with a greater or less number of properly shaped and arranged mouldboard-like teeth, and with their centre beams projecting in front for the proper attachment of wheels and draught clevises. They have handles like those of a plough, and their several beams are so connected by joints that their widths can be increased or diminished as they are required for working between drills or before planting. Horse hoes, according to the above classification, differ from cultivators chiefly in the form and arrangement of their teeth, which, having to operate in ground grown more or less hard between the time of planting and that of the first hoeing, have more of a cutting form, while they can be adjusted to turn the earth from the plants when these are young and tender, and toward them when demanded by a more advanced growth. Horse hoes in the United States are single implements, while in England they are generally constructed to work between a number of rows of plants at the same time; their use in the former country being chiefly for the culture of potatoes and Indian corn, the rows of which are at wide distances. So great is the public sense of the recently discovered importance of a thorough and repeated pulverization of the soil for the easier and more effective operation of those forces by which the various necessary gases are carried to the roots of plants, and for the proper decomposition of humus and the manures, that these implements are now made in all parts of the country; one house alone making 4,000 of them in one season, while another, which confines its operations chiefly to making the teeth of the implement for some of the various smaller establishments, sold 40,000 of these between Feb. and Aug. 1857.

CULVERIN (Fr. *couleuvrine*, from Lat. *colubrinus*, serpent-like), a long and slender piece of ordnance, equal to an 18-pounder, and carrying a ball to a great distance.

CULVERT, an arched channel for the conveyance of water under ground. Channels of this description are very common in the embankments of railways and canals.

CULVERT, George, a head chief and warrior of the Choctaw nation, born in 1744, died at Fort Towson, Ark., Nov. 1839, served under Washington in the revolution, and from him received a commission of major of militia in the U. S. service and a sword. He served under Wayne, and also under Jackson against the Seminoles in 1814. For his bravery, Jackson presented him with a colonel's commission, and afterward (during his presidency) with a sword. He educated his sons and established them on plantations among his people.

CUMÆ, or Cuma, one of the most ancient and celebrated of the Greek cities of Italy, situated on the Campanian shore a little N. of Baiæ. It is said to have been founded by a joint colony from Æolian Cyme and Eubœan Chalcis. The time of its foundation is uncertain, but of its extreme antiquity there can be no doubt, for it was in the zenith of its prosperity and power, ruling over the Campanian plain and the Tyrrhenian sea, while Rome was yet in its infancy. Cumæ was the mother of many famous and flourishing colonies in Italy and Sicily; and of the extent of its commerce and opulence, before the establishment of the Etruscan supremacy, the harbors of Dicæarchia and Misenum were splendid evidences. As the Etruscans became powerful, however, the Cumæans declined, first losing their maritime superiority, then the dominion of the Campanian plain, and ultimately every thing without their city walls. After being thus stripped of their possessions, and when beleaguered both by sea and land by their victorious foes, they applied to Hiero of Syracuse for succor, and by means of the auxiliaries he sent them they were enabled to defeat their enemies once more, and to secure themselves from attack for many years. But the warlike Samnites, after wresting all their southern conquests from the Etruscans, laid siege to Cumæ, took

it, 420 B. C., put most of the male inhabitants to the sword, or sold them as slaves, and planted a colony of their own countrymen in the captured city. In 338 B. C. Cumæ became a Roman *municipium*. During the second Punic war Hannibal besieged it in vain. During the wars of the Goths and Byzantines Cumæ acquired a temporary importance as the last stronghold of the Gothic kings in Italy. After its capture, however, by the army of the victorious Narses (A. D. 552), it rapidly sunk into insignificance. Some remains of the city are still to be traced on the Mediterranean shore. A cavern in the rock on which the acropolis stood is still pointed out as the place where the famous sibyl resided and uttered her oracles. In 1853 the prince of Syracuse discovered there a magnificent temple of Diana; and over 150 tombs were explored in the same year, resulting in the discovery of a great variety of antiquarian treasures. An interesting paper on the waxen heads found in one of the tombs was read, May 28, 1856, before the London archæological association, by Mr. Pettigrew, who exhibited a glass vase, a tooth comb, and other antiquities obtained there by Mr. Wansey, who had attended the prince of Syracuse in some of his excavations.

CUMANA, a province of Venezuela, comprising part of the region sometimes called New Andalusia, bounded N. by the Caribbean sea, E. by the gulf of Paria, S. by the Orinoco, and W. by the province of Barcelona; area, 17,309 sq. m.; pop. in 1846, 75,828. A range of mountains crosses it parallel with the sea, and sends off several ridges toward the south. These hills are steep, but not very high, and covered with dense forests. The valleys and plains, watered by many rivers, the chief of which are the Cari, Mamo, Limones, Guaraco, Guarapichi, Manzanares, and Cariaco, and dotted over with lakes, produce excellent pasturage, sugar, and grain. The peninsula of Araya, on the N. coast, has been noted for several centuries for the production of salt, the consumption of which in Barcelona for curing provisions amounts to about 1,200,000 lbs. per annum, ⅓ of which is obtained from Araya. The principal exports are dried fish, salted meat, hides, cotton, cocoa, and medicinal plants.—CUMANA, or NEW TOLEDO, the capital of the above province, is situated near the mouth of the gulf of Cariaco and on the river Manzanares, 1 m. from the sea; lat. 10° 27′ 52″ N., long. 64° 4′ 47″ W.; pop. about 12,000. It is defended by the fortress of San Antonio, built on a rocky eminence, on which are also the ruins of the castle of Santa Maria. It has an excellent port, capable of receiving all the navies of Europe, but its shipping is insignificant. It has suffered too severely from earthquakes to present much architectural beauty. On Oct. 21, 1766, severe shocks destroyed the entire city in the space of a few minutes; and a similar visitation, Dec. 14, 1797, laid ⅓ of the town in ruins. The climate is exceedingly hot, the temperature from June to October reaching 90° and 95° F. during the day, and seldom falling below 80° at night. Cumana was founded by Diego Castellon in 1523. It has 3 suburbs, the aggregate population of which nearly equals that of the city itself.

CUMANIA, GREAT and LITTLE, two districts of Hungary.—GREAT CUMANIA (Hung. *Nagy Kunság*), in the circle "beyond the Theiss," consists of a low plain, subject to frequent inundations from the rivers, and occupied to a great extent by swamps; area, 424 sq. m.; pop. about 55,000, of whom the majority are Protestants. Cumania differs from most Hungarian districts in having no large land-owners, or feudal lords. The inhabitants, before the revolution of 1848, had a government of their own, and sent representatives to the Hungarian diet. They are a robust, plain, and patriotic people, fond of rural pursuits, and moderately wealthy.—LITTLE CUMANIA (Hung. *Kis Kunság*) consists of several detached portions of land in the circle "this side the Theiss," and is more than twice as large as Great Cumania, having an aggregate area of about 1,000 sq. m.; pop. about 64,000. In physical aspect, general characteristics, and the condition of its inhabitants, it closely resembles Great Cumania.—Both districts have their name from settlements of Cumani, a people of Tartar race, who from the 11th to the 14th century acted a conspicuous part in the history of the nations of eastern Europe.

CUMBERLAND, the name of counties in several of the United States. I. A S. W. co. of Maine, area about 990 sq. m., bordering on the Atlantic, and bounded on the N. E. by the Androscoggin river; pop. in 1850, 68,892. The coast is indented by a number of bays, the principal of which, Casco bay, affords facilities for navigation and the fisheries hardly surpassed on the Atlantic coast. The surface of the county is pleasantly diversified by several small lakes or ponds. From Sebago pond, the largest of these, a canal has been opened to the ocean. The soil is fertile and well cultivated. In 1850 it produced 233,870 bushels of corn, 266,586 of potatoes, 130,465 of oats, and 94,535 tons of hay. There were 134 churches, and 22,724 pupils attending public schools. Capital, Portland. II. A S. W. co. of N. J., area 480 sq. m., bounded S. W. by Delaware bay, and E. by Tuckahoe creek; pop. in 1855, 18,966. With the exception of some ranges of hills between the streams, the surface is generally level. East of Cohansey creek, which intersects the county, the soil is light, sandy, and overgrown with pine forests; west of the creek it is composed of clay and sandy loam. Marl is obtained in this part, and Greenwich township has some mines of iron. In 1850 the productions were 370,267 bushels of corn, 78,000 of wheat, 84,408 of oats, 116,144 of potatoes, 21,795 tons of hay, and 174,802 lbs. of butter. There were 40 churches, and 4,215 pupils attending public schools. This county was formed in 1748, out of a part of Salem county. Capital, Bridgeton. III. A S. E. co. of Penn., area 545 sq. m., lying chiefly within the Kittatinny or Cum-

berland valley, between Blue and South mountains; pop. in 1850, 34,327. The Susquehanna river flows along its eastern boundary, and Conedogwinit creek intersects it. Limestone of superior quality exists here in profusion, and iron ore has been found in some places. The soil is remarkably rich, and agriculture is in a very forward state. The productions in 1850 were 487,182 bushels of wheat, 361,166 of corn, 422,100 of oats, 31,788 tons of hay, and 782,587 lbs. of butter. There were 40 flour and grist mills, 17 saw mills, numerous founderies and factories of various kinds, 5 newspaper offices, 74 churches, and 8,887 pupils attending public schools. Organized in 1750, and named from Cumberland county, England. Capital, Carlisle. IV. A S. E. co. of Va.; area, 310 sq. m.; pop. in 1850, 9,751, of whom 6,329 were slaves. The surface is moderately uneven, and the soil was originally productive, but now in some places worn out. The principal rivers are the Appomattox, which forms its S. E. boundary, James river, which flows along its N. frontier, and Willis river, which intersects it. In 1850 it yielded 118,616 bushels of wheat, 220,535 of corn, and 2,476,135 lbs. of tobacco. There were 16 churches, and 275 pupils attending public schools. Value of real estate in 1856, $2,043,148. The county was formed from Goochland in 1748. Capital, Cumberland Court House. V. A S. central co. of N. C.; area estimated at 1,680 sq. m.; pop. in 1850, 20,610, of whom 7,217 were slaves. It is intersected by Cape Fear river, and in great measure occupied by vast forests of pitch pine. Large quantities of turpentine and lumber are obtained from these forests, and exported by means of steamboats down Cape Fear river. The soil is generally good, and the surface considerably diversified. About ⅓ of the county lies within the hilly and granite region of North Carolina; the remainder is low and level. Several plank roads have recently been built in different parts, and by the facilities which they present for the transportation of the produce of the interior, have contributed greatly to the prosperity of the county. In 1850 the harvest amounted to 376,843 bushels of corn, 142,396 of sweet potatoes, and 156 bales of cotton. Organized in 1754. Capital, Fayetteville. VI. A S. co. of Ky., bordering on Tenn., bisected by Cumberland river (from which it is named); area, about 375 sq. m.; pop. in 1850, 7,005, of whom 1,485 were slaves. The surface is hilly near the river, and the soil of moderate fertility. Productions in 1850, 7,850 bushels of wheat, 434,340 of corn, 30,020 of oats, and 1,238,802 lbs. of tobacco. Number of pupils in the public schools, 1,552. There is a remarkable "oil spring" near the river. Capital, Burksville. VII. An E. co. of Ill.; area, 310 sq. m.; pop. in 1855, 6,099. It is intersected by Embarras river, and diversified by forests and prairies. The soil is fertile, and in 1850 produced 217,015 bushels of corn, 5,122 of wheat, and 33,906 of oats. There were 2 churches. Capital, Greenup.

CUMBERLAND, a river of Ky. and Tenn., rising in the Cumberland mountains, near the S. E. boundary of Ky., flowing W. and S. W., and entering Tenn. between Jackson and Overton counties. After a circuit of nearly 250 m. through middle Tenn., it makes a bend to the N. W., recrosses the Ky. border about 10 m. from the Tenn. river, and runs nearly parallel with that stream until it joins the Ohio at Smithland. Its whole course is estimated at over 600 m. At high water it is navigable by steamboats to Nashville, 200 m. from its mouth, and by small boats for a distance of nearly 500 m. Not far from Williamsburg, in Kentucky, it has a remarkable vertical fall of 60 feet. It drains an area of about 17,000 sq. m.

CUMBERLAND, a thriving town and capital of Alleghany co., Md., on the left bank of the Potomac river, and on the Baltimore and Ohio railroad; pop. in 1850, 6,073. It is the W. terminus of the Chesapeake and Ohio canal, and the E. terminus of the national road. A few miles west of the town, upon the summit of the Alleghanies, commences the district known as the Cumberland coal region, which extends west to the Ohio river. The mines of the eastern portion produce an excellent quality of semi-bituminous coal, and are worked by several mining companies. In 1857 the quantity sent to market was 612,291 tons. Iron ores in the same region, and others of the older formations nearer Cumberland, have given support to a few blast furnaces. The town contains the county buildings, several churches, 3 newspaper offices, 1 bank, and 1 savings institution; has an excellent trade, and next to Baltimore is the largest town in the state.

CUMBERLAND, a N. W. co. of Nova Scotia, bordering on Northumberland strait, and partly separated from New Brunswick by Chignecto bay; area, 1,020 sq. m.; pop. in 1851, 14,339. Its coasts are marked by an immense number of small bays and good harbors. The surface inland is rough and mountainous. The wealth of the county consists principally in coal mines, which are very extensive and among the most valuable in Nova Scotia. The North American mining company annually obtains from these beds large quantities of excellent bituminous coal. Gypsum is also found, and grindstones are made from the rock which underlies the surface. Capital, Amherst.

CUMBERLAND, a N. co. of England, separated from Scotland by Solway frith and the Esk and Liddle rivers, and bounded W. by the Irish sea; area, 1,565 sq. m., or 1,001,600 acres, ⅔ of which are under cultivation; pop. in 1851, 195,492. The surface of the N. and N. W. parts is low and flat or gently undulating; the midland districts are traversed by hills, and the E. and S. W. parts are occupied by lofty mountains, among which are the famous summits of Skiddaw (3,020 feet above the sea), Saddleback (2,787 feet), and Helvellyn (3,055 feet). In this picturesque district are lakes Ulls-water, Thirlmere, Bassenthwaite, Derwent-water, But-

termere, Crummock, Lowes-water, Ennerdale, and Wast-water, renowned for their romantic scenery, and often visited by travellers. The principal rivers are the Derwent, Eden, and Esk. The soil of the valleys and river bottoms is generally rich; the lowlands have been much improved by draining and are very productive; the mountainous districts are fit for little but sheep pastures. Agriculture has improved of late years, and a great deal of grain and other produce is exported. The chief minerals are coal, iron, silver, plumbago, copper, lead, and limestone. The first 3 are abundant, and the iron ore is said to yield more than double the average proportion of metal. The lead mines near Alston belong almost exclusively to Greenwich hospital. A considerable extent of the great Roman wall erected by Hadrian is in this county, and many Roman remains of various kinds have been found here. The county suffered much from the Picts, Scots, and Danes, and was the arena of almost constant warfare during the border troubles. At the time of the conquest it was in such a state of desolation that William remitted its taxes, and it was not included in the Domesday book. The chief towns are Carlisle, Whitehaven, Cockermouth, Penrith, Keswick, and Egremont. It is traversed by the Lancaster, Kendal, and Carlisle, the Newcastle and Carlisle, the Carlisle and Maryport, and the Workington and Cockermouth branch railways. A ship canal extends from Carlisle to the Solway frith. The county returns 4 members to the house of commons.

CUMBERLAND, Richard. I. An English divine, born in London, July 13, 1632, died Oct. 9, 1718. He was a good linguist and zealous student, and when upward of 80 took up the study of Coptic, in which he attained considerable proficiency. He was appointed bishop of Peterborough by William III. without solicitation, the monarch having been informed on trustworthy authority that Dr. Cumberland was the fittest person for the vacant see. He learned the fact of his nomination by reading it in the newspaper of the day. His principal works are a translation of Sanchoniathon's "Phœnician History," with notes and dissertations; *Originis Gentium Antiquissimæ* ("Attempts for discovering the Times of the first Planting of Nations"); and an "Enquiry into the Laws of Nature" (written originally in Latin, and translated by the Rev. J. Tower). II. An English dramatist, born in Cambridge, Feb. 19, 1732, died May 7, 1811. He was great-grandson of Bishop Cumberland, and grandson of Richard Bentley. His connections procured him an early introduction into political life; and after having filled the office of secretary to Lord Halifax, with other minor appointments, he was in 1775 made secretary of the board of trade, an office which was abolished in 1782, when he received a compensation allowance. He published the "Observer," a series of essays, in which he displayed considerable classical learning, with much wit and elegant composition. He wrote a large number of dramatic pieces, the most successful of which were the "West Indian" and the "Wheel of Fortune," still stock pieces on the stage. He was a copious writer on a great variety of subjects, and among his works are several novels and a collection of anecdotes of Spanish painters. He published his memoirs in 1806.

CUMBERLAND, William Augustus, duke of, 3d son of George II. of England, born April 26, 1721, died at Winsdor, Oct. 31, 1765. He was present at the battle of Dettingen, where he was wounded. In 1745 he received the command of the allied army, and fought the celebrated battle of Fontenoy against Marshal Saxe, in which the French were victorious. He was next sent against the pretender in Scotland, and overthrew the army of malcontents at the battle of Culloden; but the glory of this victory, such as it was, was stained by the cruelties and excesses of the victors. He was appointed by the king commander-in-chief of the British army, and was next sent to the Netherlands; was defeated at Lafeldt by Marshal Saxe in 1747, and gained no advantages in this war, which was terminated by the peace of Aix la Chapelle. At the commencement of the 7 years' war the king of England's Hanoverian dominions had to be defended at any cost to the English nation; accordingly the duke of Cumberland was despatched to Germany, when the victory of Marshal d'Estrées at Hastenbeck forced him to the disgraceful convention of Closter Seven (1757), by which the English army, 40,000 strong, was disarmed and disbanded, and Hanover was placed at the mercy of the French, who ravaged it at their will. On his return to England the king was so dissatisfied that the duke of Cumberland threw up his appointments, and was never again invited to take office.—For the duke of Cumberland, afterward king of Hanover, see Ernst August.

CUMBERLAND MOUNTAINS, that portion of the Appalachian group which ranges along the S. W. border of Virginia and the S. E. of Kentucky, and thence passes across the state of Tennessee into the N. E. part of Alabama. It spreads over a width of about 50 m., parallel ridges alternating with longitudinal valleys. The ridges rarely exceed 2,000 feet in height. They are rocky and little cultivated, but the valleys are fertile. These mountains lie west of the range of the granite and metamorphic rocks, which compose the mountains on the W. borders of North Carolina and the N. part of Georgia. They are upon the range of the great coal formation of the middle states, and essentially composed of the same groups of stratified rocks as those of the Alleghany mountains, Chestnut ridge, and Laurel hill in Pennsylvania. The Tennessee river and its branches drain its E. slopes, until this river crosses their range and unites with the Cumberland, the sources of which are on its W. side.

CUMBERLAND PRESBYTERIANS, a denomination of Christians which took its rise during the religious revival in Kentucky and

Tennessee in 1801–'3. So great was the excitement, and so vast the multitudes who came from all parts of the country to the camp meetings, that it was found impossible to supply the demand for ministers, and laymen were appointed to preach by the presbytery of Transylvania. Their reception, however, was strenuously opposed by some of the clergy, and they were refused ordination. A new presbytery, which was formed in 1803 in the southern part of the state, denominated the Cumberland presbytery, subsequently received them and granted them ordination, at the same time taking on trial as licentiates others of similar qualifications. The action of the presbytery in this matter was reviewed by the synod of Kentucky, which denied its validity, and appointed a commission to examine the newly ordained ministers both in regard to their attainments and the doctrines which they held. The result was, that the course pursued by the Cumberland presbytery was condemned, and the sentence of the synod confirmed by the general assembly of the Presbyterian church. The presbytery, demurring to this decision, withdrew from the jurisdiction of the general assembly, and in 1810 organized a distinct and separate body, which has since that time been known as the Cumberland Presbyterian church. Their progress as an independent church was marked with great success, so that in 1813 they formed a synod and adopted articles of religion and a form of church government. In doctrine they occupy a sort of middle ground between Calvinism and Arminianism. They reject the doctrine of eternal, unconditional election and reprobation, and believe in the universality of the atonement and the final conservation of the saints. Their government is presbyterian in form, embracing the session, presbytery, synod, and general assembly, all of which are constituted in the same manner as those of the Presbyterian church. Though they have local pastors, they have adopted the itinerant system of the Methodists. By this system of circuits and stations their ministers have spread themselves over the West and South, and even to California. Their general assembly has under its supervision 17 synods, 48 presbyteries, 1,000 churches, 300 ministers, 480 licentiates and candidates, and a membership of 100,000. Several religious journals are published under their auspices, and they have flourishing colleges in Kentucky, Tennessee, and Ohio, beside 10 seminaries.

CUMING, Hugh, a living English naturalist, born about 1800, and residing in London. His collection of shells, over 60,000 in number, has for several years been famous as one of the finest in Europe. In 1848 it represented more than 19,000 species and varieties, and has since been much increased from the principal cabinets on the continent, which Mr. Cuming visits annually, carrying the duplicates of his rarities and exchanging them. His specimens are wonderfully perfect in form, texture, and color, and have been amassed not only by diligently frequenting the shops of commercial naturalists in seaports, but also by passing 30 years of his life in travel and personal researches, collecting every variety of mollusks from their native seas and rivers, in the Atlantic, Pacific, and Indian oceans, and in the islands of the Malay archipelago. He has thus been able to describe the native habitats and habits of most of his shells. His stores are freely opened to scientific men, and have furnished subjects for many important papers in scientific publications.

CUMMIN SEED, the fruit or seed of the *cuminum cyminum*, an umbelliferous plant, cultivated in the East from the remotest times for its seeds, which have a bitter and aromatic taste, and a peculiar odor. The Latin poets allude to their power of producing languor. They are obtained in Egypt, Greece, Malta, and Sicily.

CUMMING, John, D.D., a popular preacher of London, born in Aberdeenshire, Scotland, Nov. 10, 1810, was educated at King's college, university of Aberdeen, and prepared for the Scottish church, but on completing his theological studies, engaged as tutor in a school near London. Here he continued until 1832, when, having been previously licensed by the Scotch presbytery of London, he became the minister of the Scotch church in Crown court, Covent Garden, a relation which he still holds. He is distinguished for eloquence, both in the pulpit and on the platform, for controversial acuteness, and for his devotion to the interests of the Scottish church. Of this latter cause he has been the principal representative in London, opposing himself steadily to the non-intrusion movement of which Chalmers was the leader. As an author, Dr. Cumming is well and favorably known both at home and in this country, and most of his numerous works have been republished in America. His "Apocalyptic Sketches," "Lectures on the Parables," and "Voices of the Night," have had a wide circulation.

CUMMING, Roualeyn George Gordon, a Scottish sportsman and author, born March 15, 1820. He is the second son of Sir William Gordon Gordon Cumming, and from an early age had abundant experiences in hunting as a deer-stalker in the highlands of Badenoch. He spent some years in the military service in India and the Cape of Good Hope, but left the army about 1843. Between October of that year and March, 1849, he made 5 hunting expeditions into various parts of South Africa, which he has recorded in his "Hunter's Life in South Africa," published in London in 1850, and republished in the United States. His adventures, as related by himself, partake so largely of the marvellous that their accuracy has more than once been called in question. A more serious charge against him is his indiscriminate and useless slaughter of a variety of harmless animals, which he destroyed apparently for no other purpose than to increase the list of his victims. He derived a considerable profit from the skins, tusks, and other trophies of the chase, of which he opened a remarkable exhibition on his return to England. He claims to have killed

more than 100 elephants. Of late years he has found sport chiefly in the Scottish highlands.

CUMMINGS, Joseph, D.D., president of the Wesleyan university at Middletown, Conn., born in Falmouth, Me., in 1817, was graduated at that institution in 1840, and was chosen professor of natural science in the Amenia seminary, N. Y. In 1841 he was licensed to preach, and in 1843 became principal of the seminary. In 1846 he joined the New England conference, and occupied several important stations, after which he was appointed professor of theology in the Methodist general Biblical institute, at Concord, N. H. Subsequently he was president of Geneva college, N. Y., for 4 years, when he was elected to his present position.

CUNDINAMARCA, a central department of New Granada, comprising the table-land of Bogota, a small part of the *llanos* near the sources of the Meta and Guaviare, and the valleys of the lower Cauca and the upper and middle Magdalena; pop. in 1853, 564,955. It is well timbered, contains gold, silver, copper, lead, coal, and rock salt, and produces almost every kind of crop common to New Granada. The cataract of Tequendama and the natural bridges of Iconozo and Pandi are in this department. Capital, Bogota.

CUNEGO, Domenico, an Italian engraver, born at Verona in 1727, died in Rome in 1794. His principal works are 22 plates in Gavin Hamilton's *Schola Italiana*, and his outline of the "Last Judgment," from Michel Angelo's frescoes in the Sistine chapel.

CUNEIFORM INSCRIPTIONS, or Sphenograms (Gr. *σφην*, Lat. *cuneus*, a wedge), called also Claviform, Cludiform (Lat. *clavus*, mediæval *cludus*, a nail), and Arrow-Headed Inscriptions, are monumental records of the inhabitants of the ancient Assyrian, Babylonian, and Persian empires. They consist of letters, some syllables, and a few monograms or compends, which contain two principal elements, namely, a figure resembling a wedge, nail, or arrow-head, and a less frequent figure like a broken bow or a swallow-tail (Fr. *chevron*). Some other shapes, such as a hammer, a dagger, angles of parallel insertion, mere lines, &c., all without a curve, are less frequent. They are either cut or stamped upon the substance bearing them, according to the nature of the material. They occur on tablets cut in rocks, on stone slabs, on bass-reliefs, on winged bulls, on vases, gems, seals (some being so minute as to require a microscope), on sun-baked or kiln-burnt bricks or small cylinders; and mostly in horizontal lines. They are read from left to right. Most of them are found within the boundaries of the ancient great Persian empire, a few only having been discovered elsewhere. Democritus called them Assyrian letters, and is reported to have written a treatise on them, and to have translated an epigraph on a pillar. The companions of Alexander the Great saw a tablet so inscribed near Anchiale in Cilicia. Pietro della Valle sent the first Babylonian brick to Athanasius Kircher in 1622. Figueroa saw sphenograms at Persepolis about the same time. Mandelslo (1637), Chardin (1673), Kämpfer, and Herbert, found traces of gold in some on the Chehel-minar (40 pillars, formerly called Hezer-situn, 1,000 columns, of which only 15 were standing at the time of Ker Porter's visit in 1815). Chardin, Cornelius Le Bruyn, and Gemelli-Carreri, at the close of the 17th century, copied some on the site of Persepolis and elsewhere. Tavernier and others also published some account of them in 1663. Kermanshah (Carine), W. of Behistun, was visited in 1737 by Otter, and in 1743 by Em. de St. Albert, whom D'Anville quotes as the first writer on sphenograms; by Kodja Abd ul Kurrim of Cashmere in 1741, &c. In 1765 Carsten Niebuhr copied some at Persepolis and elsewhere, more accurately than had been done before, also giving measurements of various edifices. In 1786 Bishop Beauchamp found bricks at Hillah, and his nephew, the abbé Beauchamp, visited other places beside the site of Babylon, and in 1790 wrote on the manner of searching for these monuments. André Michaux had sent a sphenogrammatic flint to Paris in 1782, and made researches on the rocks of Alvand (or Ervend, ancient Orontes), near Hamadan (eastern Ecbatana), in 1785. These places were also examined by Olivier in 1796, McKinneir in 1810, K. Porter and Bellino, by Keppell in 1824, Malcolm, Morier, Steuart, and Vidal, who copied two tablets. F. E. Schulz, who was killed by the Koords in 1829, copied, during two journeys, many inscriptions on the rocks, on church walls, grottos, &c., in and near the city of Van. One of these sphenograms contains 98 lines with 1,500 characters, and 42 others contain about 900 lines. Col. Monteith found two near Ardzish, and another on the road to Erzroum, the furthest one to the N. W., in the valley of the Little Euphrates. The indefatigable Rawlinson copied some peculiar ones on the Tash-Tepe, on religious subjects, and saw another on the Keli-Shin, a mountain pass, which was covered with ice. A sphenogram of the same nature was found by Moltke on the Euphrates, on a very high rock above Kumurhan, on the route from Ephesus to Babylon, within the chain of the Taurus, between the Armenian and Mesopotamian regions. It was copied by Mühlbach, in 1840. Lepsius published a sphenographic bass-relief from a rock on the Nahr el Kelb (Lycos) near Beyroot, in 1838, commemorating the conquest of Egypt by Cambyses, having near to it a pillar of Rhamses II. (Sesostris). Gen. Dagua copied one with the head of Darius under hawk's wings in token of his apotheosis, near Abu Kesheid, on the canal from the Nile to the Red sea. Witsen described a sphenogram at Tarku (Albana), N. of Derbend, on the Caspian sea, in the beginning of the 18th century. Schulz had intended to go in search of sphenograms to the country of the Sha-to, on Lop lake, where fire-worshippers are said to dwell. Copies of ancient MSS. belonging to the Christians of St. Thomas, in Malabar, now in the

library of Cambridge, England, contain some very ancient Persepolitan letters, with 4 others in ancient Hebrew, and one in an unknown character. J. Tod affirms that he saw many sphenograms on rocks, pillars, &c., at Mundore, in the state of Jhodpoor. Sir Harford Jones sent a great Assyrian epigraph on stone to the East India company in London, in 1803. W. Ouseley furnished materials for sphenographic literature in 1811. The widow of Claudius J. Rich republished (London, 1839) his journey to Babylon and Persepolis, made in 1811, with some valuable notices, especially on Babylonian antiquities. The greatest of all sphenograms, that of Behistun, discovered by Ker Porter, telescopically examined by Coste and Flandin, and explained by Rawlinson, is spoken of below. The rudest cunei, as to design and execution, are those found at Shuster (in Khuzistan or Susiana). Layard describes a species, containing many peculiar groups, found near Mal-Amil, between Shuster and Hamadan. A new period of sphenographic discoveries, joined with those in ancient Asiatic architecture and other great mementoes of bygone civilization, was inaugurated by P. E. Botta, the French consul at Mosul, who, encouraged by J. Mohl, disinterred a great palace at Khorsabad, in March, 1843 (*Monuments de Ninivé*, with designs by E. Flandin, 5 vols., Paris, 1849–'50). His rival, the Englishman Austen Henry Layard, exhumed 3 palaces in the mound of Nimroud in 1845, and one in that of Kuyunjik in 1848, during two visits, beside making discoveries in other places. Two of the former are the most ancient of all. The German Oppert is now (1859) engaged in examining the site of Babylon, on behalf of the French government. The number of sphenograms thus brought to light is surprising. A summary of the discoveries at Nineveh, Babylon, and Persepolis, was published in London, by Vaux, in 1851.—The origin of sphenography is enveloped in utter darkness. Ker Porter thinks it antediluvian, and connected with the tower of Babel. Brandis and others derive it from iconography, in the manner of the Egyptian demotic and the Chinese system of writing. Though no cuneiform manuscript has yet been found, Quatremère supposes a cursive style, for the purposes of common transactions, to have been the prototype of the monumental style, as well as of the square character of the Hebrews, after their return from the Babylonian captivity. Pauthier endeavored to prove the origin of cunei from a cursive style, analogous to the Zendic, Sassanidic, or Palmyrenic letters. Schöttgen attributes the introduction of sphenography into Persia to Darius. Barrois very expeditiously explains all styles of sphenography by dactylology, or the use of the fingers, in indicating the sounds of language. Gell discovered in 1812 a bronze table relating to the Olympian games, probably of the 50th Olympiad, or 577 B. C., in sphenoid letters. Some, probably accidental, resemblance to cuneiforms is also perceived in the runes of Helsingoland. W. Price saw in 1825, at Shiraz, an old manuscript in two kinds of letters, one of which seemed to him to resemble the Persian style of cunei. Niebuhr distinguished 3 styles in the Persepolitan epigraphs, and classified the most remarkable groups. In 1798 O. G. Tychsen supposed that royal titles were written over the portraits of kings, and gave some hints as to the means of reading them. With Münter, he recognized the key in a frequently recurring word, which he suspected to signify king. Münter, with Herder, in 1800, supposed that there were 3 modes of writing, viz.: alphabetic, syllabic, and monogrammatic; he thought that religious matters were written in Zend, and political affairs in Pehlevic. Joseph J. Hager, in 1801, believed the Babylonian to be alphabetic, sacred, and not composed of mere magic signs, as some had thought; having inverted the cylinders, he tried to read it in the Chinese direction downward and leftward. A. A. Lichtenstein (1798–1803) asserted the Assyrio-Persian, as he named it, to be in Cufic letters, containing sentences from the Koran, and the deeds of Tamerlane in Neo-Persian. The abbé Beauchamp believed the epigraphs to have been directions for the masons, as the inscribed side of the Babylonian bricks is found turned inward in the walls. Witte even alleged that the characters had been produced by worms. G. F. Grotefend, following the method of Sylvestre de Sacy in deciphering the Pehlevic inscriptions of the Sassanides at Naksh-i-Rustam (1803), although he had not a profound knowledge of oriental languages, attempted, on the suggestion and with the aid of Fiorillo, by logical induction, to unravel 2 inscriptions copied by Le Bruyn and Niebuhr, on which Tychsen had made trials. He guessed the 2 other writings accompanying each inscription to be of the same contents with the inscription. After a careful scrutiny of the forms of groups, Grotefend examined the Greek historians, Münter's essay, and Heeren's historical researches, to ascertain the age of the Persian kings. Then he tried to find in the epigraphs the names of Cyrus and Cambyses; but the groups had not the same initials. Cyrus and Artaxerxes were too unequal in length. Darius and Xerxes, not offering either of the difficulties, were at last discovered. The groups that might denote the father and the son were also found in proper relation with each other, on both specimens; so that the import of 4 words could be relied on. Now the value of each group, as a letter, was to be ascertained. Anquetil-Duperron's *Zend Avesta* was resorted to. But as Darius is there called *Eanteraffesh*, Grotefend examined *Weorokeshe*, which is the name of Araxes, and so arrived at the sound of the letter *x* in Xerxes, fixing its sound to be *ksh*. By repeated examinations, and aided by materials furnished to him by Bellino and others, he determined the values of *d*, *d̂*, *r*, *u*, *s*, *kh*, *p*, *t*, Eng. *j* and *f*, and came near to *b*, *dh*, *hm*, respectively, by calling them *v*, *th*, *h*. He thus gave a series of 29 letters and one compound

sign for king, and read: *Darheush*, *Ksharsha*, *Goshtaspahe*, *Akhcotshoskoh*; which Rawlinson reads: *Dáryavush*, *Khshárkhsha*, *Vishtáspahyá*, *Hakhamanishiya*. These efforts were made from 1802 to 1816, and were published in Heeren's works in 1815, and in English in 1833. In 1826 Rask rectified Grotefend's *ŏ* by changing it to *m* and *tsh* to *n*, whereby the word answering to *Achæmenius* became clear. St. Martin, following Klaproth, spoiled the *m* by changing it to *a*, and the *n* to *m*; but he agreed with both his predecessors as to *a*, *u*, *t*, *d*, *p*, *s*, and determined correctly *v*, *sh*, *y*, among his 25 letters. Eugène Burnouf (*Commentaire du Yaçna*, Paris, 1833) made out the key to the grammar of the language of the Persian text. This language is derived from the Zend, has decaying grammatic forms, foreshadowing the Neo-Persian, and approaches the Semitic type by the disappearance of vowel signs. He assigns to 15 letters different values from those given by his successors, and makes 32 letters in all, admitting *l*, which is rather *r* or *ru*. Burnouf and Christian Lassen had worked independently at first, but joined their efforts afterward. Lassen's exertions date from 1836, 1839, and 1844, when on receiving exact copies of various Persepolitan epigraphs, made by N. L. Westergaard on the spot, he changed some of his previous views, and admitted 32 Persian letters and 2 compounds (*thr*, *rp*), arranging them analogously to the Dêvanâgarî, after a rectification of the values of all his predecessors. H. C. Rawlinson, who had commenced the deciphering of the same style in 1835, having obtained an impression on paper, made by skilful Koordish climbers, of the high trilingual rock-hewn epigraphs of Behistun, published his views in 1847 ("Journal of the Asiatic Society," vol. xii.), almost totally agreeing with Lassen, and admitting 35 letters and 2 monograms (*dah*, people, and *buhmi*, earth). E. F. F. Beer reviewed Grotefend, Burnouf, and Lassen in 1837, and gave some useful hints. Jacquet also discussed the subject in 1838; he supposes the Behistun epigraphs to belong to Semiramis, and commits other inaccuracies.—The 2d Achæmenian style of trilingual sphenograms, hypothetically named Median by Westergaard, was to a great extent deciphered by him in 1844 (*Mémoires de la société royale des antiquaires du nord*, Copenhagen). He gives 16 groups of consonants, beside *t* and *th*, 6 vowels, and 72 pure syllables, with 2 ending in *s* (*as*, *ahs*); out of 82 perfect and 10 mutilated and spurious groups. He also derives compounds for *phaph*, *rph*, *thr*, *dah*, and *bumi*, counting some groups both as letters and as syllables. The reading of the whole is, however, yet hypothetical to a great extent, owing to the uncertainty of scholars as to the language in which this version of the Persian text is written. Edward Norris calls this version Tartaric, and goes so far as even to construct a Scythian grammar, by means of the Ostiak and Cheremisse dialects ("Journal of the Asiatic Society," xv.). Haug also wrote on this version in 1855.—The 3d Achæmenian style, called Babylonian by Rawlinson, very much resembles the Assyrio-Babylonian, and is yet a problem both as regards its phonetism and its language. This is almost generally admitted to be a Semitic dialect. Ernest Renan, one of the greatest modern Semitists, asserts the 2d style to be Semitic, although he denies the employment of such uncouth letters for a language whose alphabet he asserts to be more ancient and better than the oldest sphenograms. Oppert thinks the language of the 2d style nearer to Ehkili and Mahri, which are classed under the name of Cushitic, as a branch of the Semitic family. Pehlevi or Huzvaresh, an Aryo-Semitic idiom, seems to be the real language of the 2d or Median text. This disagreement of authorities, amounting even to a confusion of the two versions of the Persian text with each other, shows how little is yet known about either. M. A. Stern, encouraged by Benfey of Bonn, asserts that he has found the key to the 3d style, which is to him nearly Hebrew and Chaldaic, and which he professes to read almost without any difficulty. He rejects the whole theory of Rawlinson and of Hincks, who admit a great many ideograms, and a confused polyphony in the values of the characters. He reads each syllable otherwise than De Sacy, adopts literal groups, and classifies 257 of them in 26 categories, headed by 18 Hebrew letters (omitting *l* and *ain*), adding 32 groups for combined sounds. He accepts Botta's homophons, and sneers at Rawlinson for denying triliteral roots, and eliciting the sense of only 200 words from the Behistun text, whereas he himself has found 4 times as many, in proportion, in 15 short epigraphs. Botta does not venture on the slippery path of exegesis, but arranges the Ninevite sphenograms on the basis of 15 dominant figures, and gives a general catalogue of 642 groups, with their variants, in 15 classes, which are named from the number of elements composing them, and contain respectively as follows: 1st class, 4; 2d, 16; 3d, 29; 4th, 54; 5th, 91; 6th, 84; 7th, 77; 8th, 85; 9th, 72; 10th, 51; 11th, 29; 12th, 22; 13th, 12; 14th, 10; 15th (15, 16 or 17 elements), 6. He also gives tables of substitutions and parallels of the sphenograms of Van, Babylon, and the 3d Achæmenian. Edward Hincks, considered by some as the decipherer of the cunei of Van, having written on the Khorsabad style of Botta, afterward abandoned many of his rash assertions, and published his Assyrio-Babylonian phonetic characters, in 1852 ("Transactions of the Royal Irish Academy," 1855). He abandons the method of proper names, but relies, especially in triliteral roots, on radical analysis; asserts that all groups represent syllables, and that the characters of single syllables, exclusive of the 4 vowels (*a*, *e* or *o*, *i*, *u*), have 7 different forms (for instance, *pa*, *pe*, *pi*, *pu*, *ap*, *ip*, *up*); also that the syllabic values of many signs are fixed with all but mathematical certainty. J. Brandis attempts to exhibit what has been gained for history from the deciphering of the Assyrian

sphenograms; also the fundamental traits of the Assyrio-Babylonian system (1856); but his attempts fall very short of the mark in respect of both these objects. Barrois indulges his imagination both on sphenograms and hieroglyphs, and strenuously endeavors to write out the law tablets of Moses in arrow-heads.—The Assyrian, Babylonian, and Elymæan systems and languages still wait for an Œdipus to solve their riddles. It is certain that from time immemorial 3 peoples of different characters and languages were living in close contact and in various relations as to political power, in the countries where sphenography was practised. These 3 groups of nations are the Semitic, Aryan or Iranian, and the Turanian (Aniranian, Scythic, Tartaric, or Allophylic of various writers). Westergaard distinguishes 5 styles of sphenograms, viz.: the Babylonian, Assyrian, and the 3 on the Achæmenian monuments. Rawlinson assumes that there are 5 Assyrio-Babylonian styles, viz.: the primitive Babylonian, Achæmeno-Babylonian, Medo-Assyrian (at Van, Layard's earlier Assyrian), Assyrian (Layard's later Assyrian), and Elymæan or Susianian. Of these the Assyrian of Nimroud is, however, more ancient than the Babylonian, which is rather elongated and hence apparently derived from the former. The styles of Khorsabad and Kuyunjik are less ancient than that of the northwestern palace at Nimroud. Botta, Stern, and others attribute many of the variations to provincial and calligraphic causes. As to their configuration, the Babylonian sphenograms are most complicated, the Persian the most simple and of the latest date, having probably ended with the overthrow of the Achæmenian empire by Alexander. The vertical cunei prevail in the Persian, while the other languages abound in the horizontal. There the words are divided at the end of the lines; not so in others, which exhibit the Semitic mode, by carrying the cunei sometimes even over to the back of the slabs. In the Assyrian the wedges have 4 directions, often crossing each other, and the names of persons, God, countries, &c., are preceded by determinative monograms. The Babylonian cunei lie in 8 directions, and every epigraph on bricks begins with a star-like figure of 4 wedges crossing each other; it has also parallel angles inserted within others, and opening downward and rightward; also many dagger-like lines. Of this style, Rich distinguishes 3 species. Rawlinson thinks that the following list contains all the Persian epigraphs: 1, Morier's on the 4 broken pilasters at Murgab, near Pasagardæ, N. E. of Persepolis, containing "I, Kurush, king Achæmenian;" 2, that at Persepolis, on the palace of Darius, twice over the doors; 3 and 4, on 2 slabs, enumerating nations; 5, at Alvand; 6, at Naksh-i-Rustam, near Persepolis, on the rock-sepulchre of Darius, containing more names of conquered nations than that of Behistun; 7, one of about 60 lines, of which Westergaard copied but 2, containing probably moral and religious precepts; 8, near Suez: "Darius, king great;" 9, that on the windows of the palace of this king, in 18 places, all trilingual; 10, that of Behistun; 11, 3 only on Babylonian cylinders: "I, Darius, king." All these, except the first, are of Darius; the 8 now following are of Xerxes: 1, at Alvand, a single line, perhaps on a road-mark; 2 to 5, on various parts of his palace; 6, at Van, probably engraved on his return from Europe, copied by Schulz, and more completely by E. Boré, in 1828, a Babylonian transcript; 7, on the palace of Darius, at Persepolis, stating: "My father built this house," &c.; 8, Darius, trilingual, on the vase of Caylus, where the hieroglyphs show the phonesis: *Khshayārsha naga wazarka.* No sphenograms of Artaxerxes Longimanus or of Artaxerxes Mnemon have yet been found. The 2 of Artaxerxes Ochus exhibit barbarisms; they are: 1, on the staircase of the terrace of the palace of Darius, relating his descent from Arshama and Vishtāspahya, &c., and invoking the blessing of Ormuzd; 2, the legend in Babylonized orthography: *Ardakhchashcha naga wazarka*, "Artaxerxes, king great," upon an Egyptian vase, in hieroglyphs and the 3 Achæmenian species, preserved in the treasury of St. Mark's, at Venice. The most recent of all known sphenograms, with mixed characters, is that of Tarku, which Burnouf attributes to one of the 30 Arsacidæ, kings of Parthia (250 B. C. to A. D. 226). Herodotus mentions 2 pillars of Darius on the Bosporus, erected while he was assailing the Scythians, with the names of the nations in his army; the one in Greek, the other in Assyrian.—Rawlinson's Behistun inscription consists of 4½ great Persian columns and 11 detached pieces, embracing as much of the language as had been previously discovered from all other monuments put together. The 5 columns of the so-called Median are partly mutilated, and the Babylonian version is only on 4 columns. This document is inscribed upon the sacred rock on the W. frontiers of Media, on the high road from Babylonia eastward. The hill of Bagistane (God's place), rising abruptly from the plain to a vertical height of about 1,700 feet, was most fit for a memento of the deeds of Darius, immediately after he ascended the throne. It informs the world, that while occupied in the reform of the national faith, an insurrection was easily checked in Susiana; that soon afterward a pretended son of Nabonidus of the house of Nabonassar was conquered in Babylon; that a league between Media, Assyria, and Armenia was defeated with great difficulty by himself in person; and that several other insurrections, especially a most dangerous one in Persia, raised by another pseudo Smerdis, had been suppressed. When probably on the road to Babylon to quell a new rebellion, and he heard of its being put down, he engraved his thanksgiving to Ormuzd on this sacred spot, in the 5th year of his reign (516 B. C.). The incision is about 300 feet from the base of the rock; and its inaccessibility preserved it from the iconoclastic fury of Islam. For extent, beauty of execution, uniformity, and correctness, this in-

scription is perhaps unequalled, the Persian being superior to any engraving even at Persepolis, the Median equally admirable. A coating of silicious varnish is yet visible on the tablet, where it has not fallen off from the limestone, which is softer than this covering. Darius begins by proclaiming his genealogy and titles in the following strain: *Adam Dārayavush, khshāyathiya vazarka, khshāyathiya khshāyathiyanām, khshāyathiya Pārsiya, khshāyathiya dahyaunām, Vishtāspahyā putra, Arshāmahyā napā, Hakhāmanishiyā.* Regularly translated into Latin, which language admits the inflections of the original, this is: *Ego Darius, rex magnus, rex regum, rex Persiæ, rex gentium, Hystaspis filius, Arsamis nepos, Achæmenius.* Some defective Persian passages are restorable from both versions or from either, and *vice versa.* All other paragraphs or specific proclamations begin thus: *Thātiya Dārayavush khshāyathiya* (*Prædicat Darius rex*). The 6th of the 1st column enumerates, after the heading, the provinces of his empire, thus: *Imā dahyāva tyā manā patiyāisha, vashnā Auramazdāha adamshām khshāyathiya āham* (*Ecce regiones quibus ego potitus; gratia Ormuzdi ego fuctus rex sum*): *Pārsa, 'Uvaja, Bābirush, Athurā, Arabāya, Mudrāya, tyiya darayahyā, Saparda, Yunā, Māda* (restored from the Scythic *Ma-pata*), *Katapatuka, Parthva, Zaraka, Hariva, 'Uvārazmiya, Bakhtarish, Suguda, Gadāra, Saka, Thatagush, Hara 'uvatish, Maka, fraharvam dahyāva XXIII* (*Persia, Susiana, Babylonia, Assyria, Arabia, Misra* [*Ægyptus*], *quæ maritimæ, Saparda, Ionia, Media, Cappadocia, Parthia, Zarangia, Arya, Chorasmia, Bactria, Sogdiana, Gandaria, Sacæ, Sattagydia, Arachosia, Mecia, simul provinciæ XXIII*). J. Oppert, one of the latest investigators of Babylonian and other kindred antiquities, published in 1857 the translation of the inscription on the sepulchre of Darius I. at Naksh-i-Rustam. He believes it to be next in importance to that of Behistun; and he calls the first version of the Persian text Medo-Scythic, and the second Assyrian. It runs thus: *Baga vazarka Auramazdâ hya imâm bumim adâ hya avam asmânam adâ hya martiyam adâ hya Siyatim adâ martiyahyā hya Dārayavum khsâyathiyam akunaus aivam paruvnām khshâyathiyam aivam paruvnâm framâtâram*, &c.; in Latin: *Deus magnus Ormazdes, qui hanc terram creavit, qui istud cœlum fecit, qui hominem fecit, qui imperium dedit homini, qui Darium regem constituit unum multorum regem, unum multorum imperatorem*, &c. Next follow his titles and genealogy, and the names of his provinces, viz.: *Māda, Uvazā, Parthava, Haraiva, Bākhtris, Sugda, Uvarazmis, Zaranka, Harauvatis, Thatazus, Gāndāra, Hindus, Sakā humargā, Sakā tigrakhauda, Yaunā Sakā tyaiy paradaruya, Skudra Yaunā, Putiyā, Kusiyā, Maciyā, Karkā*; in Latin: *Media, Elymaïs, Parthia, Aryana, Bactria, Sogdiana, Chorasmia, Sarangia, Arachotis, Sattagydia, Gandaria, India, Scythæ pastores, Scythæ sagittarii; qui trans mare: Scodri Iones crinibus plexis* (European Greeks), *Put, Cus, Maxyes* (Libyans), *Carthago.* Then follows a passage concerning the usurper Pseudo-Smerdis: *Auramazdā yathā avaina imâm bumim yâtum pasāva dim manā frābara mām khshāyathiyam akunaus*, &c.; *adam sim gâthavâ niyasādayam*, &c.; in Latin: *Ormazd quum vidisset hanc terram magicam* (under the superstition of the Magi), *tunc eam mihi tradidit*, &c.; *ego in rectum reposui*, &c. Oppert agrees with Niebuhr and Heeren, in following Herodotus in the belief that the rebellion of Gaumata, recorded at Behistun, was that of Smerdis the Magian both as a national and religious, or Medo-Magian, leader. But Rawlinson and others contend that it was merely an attempt to substitute the rule of the priests for that of the warriors. Magism, as the religion of Turan, was opposed to the Mazdeism of the Aryan Persians and Medes. The latter was upheld by the Achæmenian dynasty, as a state religion, even after it had yielded to the former in Media. On account of the restoration of the temples and worship, after the overthrow of Gaumata, Darius was believed by some to have been contemporary with Zoroaster. The Achæmenidæ were one of the 13 tribes of the Pasagardæ. The families of the 6 conspirators, who had assisted Darius against the first rebel Magus, had the privilege of furnishing wives to the Achæmenians. There was no other nobility by birth in Persia.—The oldest Assyrian records are those of conquests. In the N. W. palace at Nimroud there are slabs, vases, &c., bearing the names of kings, an Egyptian cartouche, and the best sphenograms yet discovered. A second period shows still further traces of an intercourse of the empire with Egypt, as early as the 18th Egyptian dynasty. Egyptian monuments confirm this intercourse reciprocally, as shown by H. Brugsch (*Geographie der Nachbarländer Aegyptens*, Leipsic, 1858). The results of a thorough and unprejudiced comparison of the Assyrian monuments with those of Egypt, are likely to upset a great many theories on the races, politics, religion, industry, and fate of the early inhabitants of western Asia.—Among the numerous legends on Babylonian bricks, cylinders, &c., the standard one of Nebuchadnezzar is the most remarkable. It begins with his titles, continues with prayers to Merodach and Nebo, then records the wonders of Babylon, viz.: the great temple of Merodach (the mound of Babel is its tower), the Borsippa temple (Birs Nimroud), and other temples, and finally describes the city, thus: "The double enclosure which Nabopolassar, my father, had made, but not completed, I finished. With 2 long embankments of brick and mortar he bound its (Euphrates) bed, made a bridge, &c. The Irgar-Bel and the Nimiti-Bel—the great double wall of Babylon—I finished," &c. In this legend the names of many works at Babylon and Borsippa, mixed with invocations to the gods and wishes for the duration of various edifices, are mentioned in great detail. It may also be remarked that the bricks were mixed with chopped straw, and often glazed; that the walls built with them

were cemented with bitumen. No remains of columns occur, either at Babylon or at Nineveh. The bricks may have been public documents, or dedications to the gods; the cylinders may have been used instead of seals; in short, most of the points concerning these remains are yet involved in obscurity.—See also Thomas Maurice, "Observations on the Ruins of Babylon" (London, 1816); Obry d'Amiens, *Revue du mémoire de Burnouf*, &c. (*Journal Asiatique*, t. ii. 1836); Cullimore "On Oriental Cylinders" London, 1842); Holzmann, *Beiträge zur Erklärung persischer Keilschrift* (Carlsruhe, 1845); "The History of Herodotus," by George Rawlinson, assisted by Sir Henry Rawlinson and Sir J. G. Wilkinson (London, 1858–'9).

CUNHA, Tristan da, a Portuguese naval commander of the latter part of the 15th century. He figures in Camoëns' "Lusiad" as a discoverer of a group of islands, the most important of which continues to bear his name.

CUNHA MATTOS, Raymunde José da, a Brazilian general, born Nov. 2, 1776, at Faro, in the Portuguese province of Algarve, died in March, 1840. He entered the Portuguese army in 1790, and served 3 years in the south of France, and 18 years in the island of St. Thomas, Africa; was then called to Rio de Janeiro, and afterward acted for some time as governor of St. Thomas. From the first he distinguished himself both as a soldier and as a writer on the countries through which he passed. In 1817 he returned to Brazil, and was appointed commander-in-chief of the artillery of Pernambuco, and subsequently military governor of the province of Goyaz. Here he collected valuable materials for a work upon the interior of Brazil, which was published in Rio de Janeiro in 1836. To this city he removed in 1826, on occasion of his election to the Brazilian legislative assembly. The military academy of Rio was placed under his direction in 1832, and shortly afterward he was promoted to the highest rank in the Brazilian army. He was secretary for life of the industrial aid society, and one of the founders and for several years vice-president of the historical society of Rio de Janeiro.

CUNHA BARBOSA, Januario da, a Brazilian prelate and statesman, born July 10, 1780, died Feb. 22, 1846. Brought up for the priesthood, he was for some time chaplain of John VI., and afterward professor of moral philosophy. In conjunction with Ledo he established (Dec. 15, 1821) a political journal at Rio de Janeiro, entitled *Reverbero constitucional fluminense*, in which he exerted a powerful influence upon the public mind in favor of Brazilian independence. After this had been declared, Cunha was at the instigation of his enemies arrested, Dec. 7, 1822, and banished to France. Two years afterward the government offered him a reparation for the injustice of which he had been the victim, by appointing him officer of the newly founded order of the Cruzeiro, and canon of the imperial chapel. In 1826 he took his seat in the first Brazilian legislative assembly as member for the province of Rio de Janeiro. The rest of his life was devoted to the political and intellectual development of Brazil. In concert with Gen. Cunha Mattos, he founded the historical and geographical society of Rio de Janeiro, and conducted the *Revista trimensal*, which recorded its proceedings. At the same time he was editor of the *Diario do governo*, a political journal favorable to the policy of the government, and of the *Auxiliador da industria nacional*, a paper devoted to the interests of agriculture and industry. These multitudinous journalistic labors did not interfere with his clerical duties, nor with the various trusts which devolved upon him as examiner of the synod, imperial historiographer, and director of the national library. He was just about to propose a comprehensive educational reform when he died. He left 2 small volumes of poems.

CUNIN-GRIDAINE, Laurent, a French manufacturer, born at Sedan in 1778, rose to the position of minister of commerce in 1837. Apprenticed in early life to the extensive cloth manufactory of Gridaine and Bernard, he became the son-in-law and partner of M. Gridaine. In 1817 he was chosen to the chamber of deputies, where he afterward opposed the administration of Polignac. After the revolution of 1830 he became secretary and vice-president of the chamber, and officiated as minister of commerce almost uninterruptedly from 1837 to 1848.

CUNNINGHAM, Alexander, a Scottish classical scholar, son of the minister of Cumnock, Ayrshire, died in 1730. The date of his birth is uncertain, as is also the place of his education, although circumstances indicate that he studied at Leyden and Utrecht, and defrayed the cost of his studies by acting as private tutor. By the interest of the Queensberry family, whom he had taught, he received from the crown the appointment of professor of civil law in the university of Edinburgh. In support of this office the Scottish parliament in 1698 voted £150 sterling annually for 10 years. The magistrates of the city, however, were jealous of the power assumed by the crown to nominate to professorships, and in 1710 they gave the place to another. Mr. Cunningham retired to the Hague, where he spent the rest of his days in philological pursuits. He enjoyed the friendship of Leibnitz, Le Clerc, and indeed of most of the scholars of the day. He published annotated editions of Horace, Virgil, and Æsop. Some of his criticisms aroused a lively controversy with Dr. Bentley. His chief work, which he did not live to complete, was a critical digest of the Pandects of Justinian. He had also in contemplation a work on the evidences of Christianity. —Another man of celebrity, named Alexander Cunningham, flourished at the same time. The two are often confounded. Both were Scotchmen, educated in Holland, the sons of clergymen; both were classical scholars, and, in their youth, tutors. The present Cunningham, a historian, was born at Ettrick in 1654, died in Lon-

don about 1737. His pupils having introduced him into the upper circles of society, he returned from Holland to England in the suite of the prince of Orange. Subsequently he was George I.'s minister to Venice, from 1715 to 1720. Long after his death his Latin manuscripts fell into the hands of his relative, Dr. Hollingbery, archdeacon of Chichester; and in 1787 Dr. William Thomson published a translation, entitled the "History of Great Britain, from the Revolution in 1688 to the accession of George I."

CUNNINGHAM, Allan, a Scottish poet and miscellaneous writer, born at Blackwood, in Dumfriesshire, in 1785, died in London, Nov. 5, 1842. He was of humble parentage, his family, which had formerly been wealthy, having lost its patrimonial estate by taking the side of Montrose. He learned from his father a love for old Scottish tales and ballads, and was sent to school till his 12th year, when he was apprenticed to a stonemason. In his 18th year, having already written several poetical pieces, he sought the acquaintance of the Ettrick Shepherd, who has left in his "Reminiscences" a notice of him as at that time "a dark, ungainly youth, with a broadly frame for his age, and strongly marked manly features, the very model of Burns, and exactly such a man." Cromek, who had collected the poetical relics of Burns, having determined to gather the remains of Nithsdale and Galloway song, engaged Cunningham for an assistant, who furnished him materials sufficient for an octavo volume, which was published in 1810. It soon appeared that Cunningham was the original author of the most beautiful pieces in the collection. At the age of 25 he went to London, and during 4 years established a literary reputation by numerous contributions to periodicals, especially to the "London Magazine." At once a mason, poet, and journalist, in 1814 he was selected by the sculptor Chantrey to be his foreman and the confidential manager of his establishment, in which congenial position he remained till the artist's death. To him Chantrey was indebted not only for many suggestions, but for numerous critiques in periodicals by which his reputation was extended. Though relieved from the necessity of depending on authorship, Cunningham continued a diligent and constantly improving writer. Some of his songs, with which his fame began, and upon which it will mainly rest, were declared by Sir Walter Scott to rival those of Burns. His various publications are: "Sir Marmaduke Maxwell" (1822), a wild drama founded upon border superstitions; several novels, often written with beauty and force, but distinguished by exaggerated ornament and extravagance of imagination, as "Paul Jones," "Sir Michael Scott," "Lord Roldan," and "Traditional Tales;" the "Life of Burns" (1834), and the "Life of Sir David Wilkie" (1843); the "Maid of Elvar," a poem; the "Songs of Scotland, Ancient and Modern, with Introduction and Notes" (1826), which contains many of his own best poems; the "Lives of the most eminent British Painters, Sculptors, and Architects" (1830), which was characterized by Prof. Wilson as "full of a fine and instructed enthusiasm;" and the literary illustrations to Major's "Cabinet Gallery of Pictures." His ballads and smaller poems are graceful, natural, airy, and eminently Scotch.—Peter, eldest son of the preceding, an English author, born in London, April 7, 1816. He was made clerk in the audit office by Sir Robert Peel at the age of 18, is one of the regular contributors to "Fraser's Magazine," and had the charge and arrangement of the works of art in the Manchester exhibition of 1857. He has written an excellent "Handbook of London," full of pleasant and curious local information, together with other interesting topographical works. He edited the poems of Drummond of Hawthornden (1833), and has edited the "Works of Goldsmith," and a new edition of "Johnson's Lives of the Poets," and is now (April, 1859) completing Croker's edition of Pope.

CUNNINGHAM, John, a British poet, born in Dublin in 1729, died in 1773. He was the son of a wine merchant, adopted the stage as a profession, in which, however, he did not attain celebrity, although he was much respected, and wrote several small volumes of poetry, distinguished by pastoral simplicity and sweetness (London, 1766, 8vo.; reprinted in the 14th vol. of Chambers's collection of the poets).

CUNOCEPHALI, or Cynocephali (Gr. κυων, dog, and κεφαλη, head), in the mythology of the Egyptians, a kind of dog-faced baboons, greatly venerated by them, and supposed to be endowed with wonderful powers. By the assistance of these animals they discovered the particular periods of the sun and moon, and it was said that half of the animal was often buried while the other half survived. The dog-head was a favorite symbol with the Egyptians. The god Anubis was represented in this manner, though the head of his image, as is rendered probable by modern researches, is that of a jackal. Cunocephali have also been found in India and elsewhere.

CUPEL, Cupellation. In the article Assaying the method of separating the unoxidizable metals gold and silver from the easily oxidized metal lead, by the process of cupellation, has been described. The cup-shaped vessels, called cupels, in which the melted alloy is exposed to a current of air playing upon its surface, are made of a paste formed of the ashes of burnt bones, mixed with water, to which a little glue may be added or not. This is kneaded into the form of a shallow cup, and dried not so rapidly that the paste shall crack. Cupels are manufactured on a large scale, to be used in separating silver and gold from lead, and from lead and copper; on a smaller scale, for use in the mints and assay office; and of very small size for blowpipe operations. The great cupels or tests used in large metallurgic operations are of oval form, 4 feet long and 2½ feet on the smaller diameter. They are constructed within a hoop or frame

of ½-inch bar iron, 4 inches deep, with several wide cross bars arranged to form an open kind of floor, upon which the sifted bone ash, mixed with about $\frac{1}{10}$ its bulk of fern ashes or $\frac{1}{40}$ its weight of pearlash, is firmly rammed. In this a cavity is scooped out with a trowel about 2¾ inches deep, leaving a wall of bone ash 2 inches thick at top and 3 at bottom, one end only retaining 5 inches thickness—the bottom 1 inch. At the thick end or breast a segment of the bone ash is removed, leaving an opening between the cupel and the hoop. The whole piece is then set in a furnace, of which it forms the floor, and after being cautiously heated, the alloy, called rich lead, is poured into it. At the end opposite the breast the nozzle of a powerful blowing apparatus is placed, so as to direct a current of air over the surface of the melted metals. A portion of the litharge sinks into the cupel, and the remainder is blown across and falls through the opening in the breast into a vessel placed to catch it.

CUPICA, a village and seaport of New Granada, on a small bay of the same name, near the entrance to the bay of Panama; lat. 6° 40′ N., long. 77° 50′ W. It has been proposed as the Pacific terminus of an interoceanic ship canal; its distance from the head of navigation on a branch of the Atrato river, which flows into the gulf of Darien, being only 17 miles.

CUPID (Lat. *cupido*, desire), called by the Greeks Eros, the god of love. In the earlier times of Grecian mythology Eros was one of the chief and oldest of the gods, and an important agent in the formation of the world, he having brought order out of chaos. But later he was the god of sensual love, and one of the youngest of the celestials. It is from this later Eros that we have our common idea of Cupid. He is the son of Venus; but the honor of his paternity is variously given to Mercury, Mars, and Jupiter. He is usually represented as a winged boy, with a bow and arrows; sometimes he is figured as blind, and he usually accompanies his mother Venus. He held sway over gods and men, and the great Jupiter himself was not secure from his attacks. He was very mischievous, and his wantonness furnished the later poets with the theme for many stories. He had sharp, golden arrows, to excite love, and blunt, leaden-headed darts, to inspire aversion in the breasts of his victims.

CUPPING, a method of local abstraction of blood, through small scarifications of the integument, by the assistance of bell-shaped glasses exhausted of air; when the object is merely to draw blood to a part, for purposes of revulsion, the exhausted glass is used without incision of the skin; the latter is called dry cupping. The old method of exhaustion was by burning a bit of paper, or a few drops of alcohol, in the interior of the glass, which was then immediately applied to the skin; a more convenient and certain exhaustion is now obtained by means of a small syringe attached to the cup; by the latter method the risk of burning the patient is avoided, the locality may be carefully selected, and the pressure accurately graduated. Even for dry cupping it is well to apply heat to the skin, in order to render it more vascular. If, after the blood be drawn to the part by a dry cup, it be desirable to deplete the vessels, the skin may be cut by a bistoury or lancet, or by an instrument for the purpose, called a scarificator; this consists of a square box of brass, in which are mounted from 6 to 16 blades, which are set and discharged by a spring; the depth of the incision can be exactly regulated, and the action is so instantaneous that very little pain is felt. From these little wounds the pump draws into the glass from 1 to 5 oz., according to its size; after sufficient blood has been drawn, a piece of adhesive plaster is put on to close them and prevent suppuration. Dry cupping is of great utility in congestions of the brain and lungs, applied in the first case to the nape, shoulders, and arms, and in the second to the back and base of the chest; also in diseases of the eyes. The amount of blood taken by cups can be well measured; they are less disgusting than leeches, quite as effectual when they can be applied, and not liable to be followed by inflammation of the wounds; they are employed both after, and in place of, general bleeding. In pneumonia, pleurisy, and abdominal inflammations, and various local affections, they are applicable when venesection would be out of the question, and are generally preferable to leeches. Cups may be used to prevent the absorption of the virus in poisoned wounds and bites. M. Junod, in France, in 1838, invented a monster apparatus, capable of receiving the whole lower extremity, in which by means of a pump the limb could be compressed or placed in a comparative vacuum; the derivative and revulsive effects of this apparatus were most energetic, amounting, if desired, to the production of syncope.

CURAÇOA, Curaçao, Curazoa, or Curassou, an island of the Dutch West Indies, in the Caribbean sea, 46 m. N. from the coast of Venezuela; lat. 12° 3′ to 12° 24′ N., long. 68° 47′ to 69° 16′ W.; length from N. W. to S. E. 36 m., breadth 8 m.; pop. in 1857, 17,864, of whom 15,076 were Catholics, 1,922 Protestants, and 866 Jews. It has a hilly surface, with rugged coasts, and is exceedingly barren. The climate is dry and hot, though tempered by sea breezes, and the island is visited by the yellow fever every 6 or 7 years. Fresh water is scarce, and is obtained either from rain or deep wells. Severe droughts frequently occur; the soil is so poor that provisions are imported, and some of the products once cultivated, as indigo, cotton, and cocoa, are now entirely neglected. Sugar, tobacco, maize, cochineal, cattle, horses, asses, sheep, and goats are raised; the tamarind, banana, cocoa palm, orange, and various kinds of kitchen vegetables, grow well, and from the lime is made the celebrated Curaçoa liqueur. Excellent fish are taken off the coast, but the staple of the island is salt, which is obtained by natural evaporation

to the amount of about 250,000 barrels per annum. Iron and copper ores exist, but are not worked. The total imports are valued at $1,000,000 annually, and the exports at $1,125,000. The principal harbor is that of Santa Anna on the S. W. coast, one side of the narrow entrance to which is defended by Fort Amsterdam, while on the other stands Willemstad or Curaçoa, the capital of the island and of a government which includes this and the neighboring islands of Buen Ayre, Oruba (or Aruba), and Little Curaçoa, and presided over since 1855 by R. F. van Lansberge. Curaçoa was settled by the Spaniards in the 16th century, taken by the Dutch in the 17th, captured by the British in 1798, restored to Holland at the peace of Amiens, again seized by England in 1806, and finally given up to the Dutch in 1814.

CURASSOW, a name given to two genera of birds of the order *gallinæ*, and the family *cracidæ;* the two genera are *crax* and *pauxi*, both peculiar to America. The curassows have the bill moderately long, strong, generally elevated at the base, with the culmen curved, and the sides compressed to the obtuse tip; the nostrils are lateral and large, with an opening partly closed by a crescentic or rounded membrane; the hind toe is long, and on the same plane with the others. In the genus *crax* the bill is moderate; the wings short and rounded, with the 6th to the 8th quills equal and the longest; the tail long and rounded; the tarsi robust, longer than the middle toe, and covered in front by broad scales; the toes long, strong, and covered with prominent scales, the lateral toes being equal; the claws are moderate, compressed, and curved. Six species are described, of which the most interesting are: 1. The crested curassow (*C. alector*, Linn.), of a general black color, with the lower belly white, and the cere yellow; the head is ornamented with a crest of recurved and frizzled feathers, radiated, alternately white and black; the sides of the head and base of the bill are bare; at certain ages the body, wings, and tail are banded with white. It is 3 feet long, about as large as a turkey. This species has frequently been carried to Europe from Guiana, and is the one generally seen in collections; in addition to its pleasing appearance, it is mild and social in its manners, and affords a savory and nutritious article of food. It inhabits the forests of tropical America in large flocks, whose peaceable members seem not to fear man unless in the neighborhood of dwellings. The nest is of very rude construction, placed upon dry branches on trees, and lined with leaves; the eggs are from 2 to 6 in number, white, resembling those of the turkey. Though living in the wildest localities, it exhibits a remarkable disposition to become tame, and flocks of them are frequently domesticated; they perch in elevated situations, on roofs and high trees; they are easily reared, as almost any kind of vegetable food agrees with them; maize, rice, bread, potatoes, and all kinds of fruits, are eagerly eaten by them. There is no doubt that these and the allied species could be introduced with advantage into the list of domesticated birds, both in this country and in Europe. 2. The globose curassow (*C. globicera*, Linn.) is distinguished by a callous globular tubercle at the base of the bill, inclining backward, covered, like the base of the mandibles, with a bright yellow cere; the general color is black, with the vent and tip of the tail white. This bird unites with the preceding and the next species, producing hybrids, which may be more or less continued by intermixture of the primitive stocks, presenting a very great variety of colors; from this has arisen many a supposed new species. 3. The red curassow (*C. rubra*, Linn.) has no tubercle on the bill, and has the region of the eyes feathered; the color of the under parts is a bright chestnut, with the head, neck, and tail banded with black and white, and occasionally with yellow. 4. The wattled curassow (*C. carunculata*, Temm.) has the head black, the belly chestnut, and the cere and naked parts red, with a black crest. The other species are *C. globulosa* (Spix), and *C. urumutum* (Spix).—In the genus *pauxi* the bill is short, and the culmen is elevated and much curved; the 6th and 7th quills are equal and the longest; the greater part of the head is covered with short velvety feathers. Three species are described: 1. The cushew curassow (*P. galeata*, Lath.), with a hard and thick oval tubercle, of a blue color, at the base of the bill; general color black, but about the vent and the end of the tail white; it is about the size of a turkey, and, like the other curassows, is readily domesticated. 2. The razor-billed curassow (*P. mitu*, Linn.) is smaller than the preceding, being about 2½ feet long; of a black color, with the belly chestnut. 3. The *P. tomentosa* (Spix).—The curassows (or hoccos, as they are sometimes called) and the pauxis, with the *penelope* or guan, are to South America what the turkey is to North America; in the state of domestication they exhibit the same traits and habits as ordinary poultry; they are polygamous, many females being attached to a single male; they are easily acclimated in Europe, and of course would be in the United States; they live in peace with other gallinaceous birds, and rarely utter any discordant cries—qualifications of which many of our domestic fowls are destitute. The flight of the curassows is heavy and ill sustained; but they run with great rapidity, carrying the tail in a pendant position. According to Sonnini, their cry may be represented by the syllables "pohic;" in addition to this they make a dull humming sound, as does the turkey, variously modified by the remarkable sinuosities of the windpipe. The trachea in the *cracidæ* differs from that of other gallinaceous birds in its remarkable circumvolutions. In the curassows proper they take place at the lower part of the neck, or in the thoracic cavity; in the pauxis they are directed on the muscles of the breast, immediately under the integuments; but in none of them does the trachea form its con-

volutions in the interior of the breast bone, as in the swans. In the crested curassow the trachea is flattened, chiefly membranous, with the rings entire and very distant from each other; it describes a broad curve between the bones of the furca, goes back 2 inches over the muscles of the neck, and then makes a second circumvolution, from which it takes the usual form as far as the lower larynx, where it is suddenly dilated. In the *pauxi*, the trachea at the opening of the thorax ascends over the right great pectoral muscle at a distance from the crest of the breast bone, continues along this muscle, and forms a curve passing somewhat behind this bone; it then proceeds over the left pectoral muscle, making a turn on the side of the breast bone, passing behind it above the first curve; then it turns again to the right, and passes over the right clavicle into the cavity of the chest. The windpipe may be shortened or lengthened by muscular action. This conformation is doubtless connected with the loud and sonorous voices of these birds. The curassows are extensively distributed over America, being found in the Guianas, Brazil, Paraguay, Mexico, Central America, and probably in some of the West India islands. It would be worthy of trial to introduce this family of birds into our southern and middle states; they would in course of time add an important article of food, and afford a new source of profitable industry.

CURATE (Lat. *curare*, to take care), the lowest degree of clerical rank in the church of England, so called from having the care of souls. The curate is the substitute or assistant of the actual incumbent. Perpetual curacies are those where there is neither rector nor vicar, but the tithes having been appropriated, the lay appropriator is obliged to appoint a curate at a stipend. In large parishes it is usual to appoint more than one curate to officiate in the parish church, and to assist the incumbent in his duties. There are also curates in chapels of ease, and in the modern foundations known as district churches, which belong to ecclesiastical subdivisions within parishes, and subordinate to the rector or vicar in some matters, though independent in others. By act 1 and 2 Victoria, the lowest stipend to be paid to a curate is £80; the sum rising, in proportion to the population of the cure, to £150, as a maximum. Curates who are not merely assistants to a rector or a vicar, are usually incumbents of churches in which no vicarage was ever established, or incumbents of foundation later than the date of the foundation of parishes, and endowed by the special bounty of particular persons.

CURCULIO, or Plum Weevil, a small beetle of the family *curculionidæ*, and genus *rhynchænus* (Fabr.), *R. nenuphar* (Herbst.). The perfect insect is about ⅛ of an inch long, of a dark brown color, variegated with white, yellow, and black spots; it looks like a dried bud when shaken from a tree, and remains motionless when disturbed, feigning death. The head is furnished with a long curved snout, bent under the thorax when at rest, which is used to make the crescent-shaped cut in which the egg is deposited; the jaws are at the end of the snout; the thorax is uneven, and the wing cases are ridged and humped, covering 2 transparent wings by which the insect flies from tree to tree; behind the humps there is a yellowish white spot; each thigh has 2 small teeth on the under side. These beetles appear between the first of April and the middle of June, according to the forwardness of vegetation. When the plums are about the size of peas, the female begins to sting the fruit, making an incision in the skin, in which she deposits a single egg; she goes from plum to plum, placing an egg in each until her store is exhausted, hardly a fruit escaping when these insects are abundant. The grubs, resembling whitish, footless maggots, with a rounded, distinct, light brown head, are hatched by the heat of the sun, and immediately burrow obliquely to the stone; the fruit, weakened by the gnawing of the grub, becomes gummy, and falls to the ground before it is ripe; by this time the grub has attained its full size, quits the fruit, and enters the ground between the middle of June and the middle of August in New England; it there becomes a pupa, and comes forth a perfect insect in about 3 weeks. Several broods may be hatched in a season, the latest ones remaining as pupæ in the ground all winter; some good authorities believe that the curculio passes the winter above ground in the perfect state, and therefore that any operations in the soil at this season can be of no advantage in guarding against its ravages. Not only plums, but nectarines, apricots, peaches, cherries, apples, pears, and quinces, are attacked by the curculio. The grubs are sometimes found in excrescences on plum trees, in which the beetle, finding in them an acid resembling that of the fruit, has deposited the eggs, and hence has often been wrongfully accused of producing these swellings. As the curculio is a good flier, any efforts to prevent its ascending the trunks of trees must be of no avail. Among remedies which have been found successful on a small scale, the following deserve mention: sudden jars of the limbs in the morning and evening in June, when they are depositing their eggs, will cause many to fall upon sheets spread beneath the trees, from which they may be collected and destroyed; scattering air-slacked lime in damp days on the trees once a week for 6 weeks, beginning soon after the fruit is discoverable; sprinkling flour of sulphur over them about the time the fruit is setting, and once or twice afterward; applying by means of a syringe a whitewash solution, rendered sticky by a little glue. All fallen fruit should be destroyed by heat, that the grubs may not escape into the ground, and give rise to a new generation; diseased excrescences should be cut out; the admission of swine and poultry about the trees will cause many of the larvæ to

be devoured before they can enter the ground.—The gray-sided curculio is pale brown, from ¼ to ⅓ of an inch long; the larvæ live in the trunks of the white oak, on which the beetles may be found about the beginning of June. Other *curculionidæ* destroy pine trees, and infest various kinds of nuts in this country. In Europe there are many species which as yet are not found here. The most destructive of the family are those which attack wheat and other grains. (See Weevil.)

CURES, in ancient geography, a town of the Sabines, 25 m. from Rome, near the left bank of the Tiber. In the time of Romulus, according to tradition, the people of Cures were united with the inhabitants of Rome, whence the latter were afterward designated Quirites. The colleague of Romulus, Tatius, and Numa Pompilius, the 2d king of Rome, were both natives of Cures. The city fell into decay at a very early period, was revived by Sylla, and was at last destroyed by the Lombards in the 6th century. The modern village of Correse occupies its site.

CURETES, priests and ministers of Cybele or Rhea. The rites and orgies with which they celebrated the worship of their deity were almost identical with those of the Corybantes.

CURFEW, the evening bell (spelled also curfeu, carfou, and courfeu, a corruption of Fr. *couvre feu*), so called from the evening bell having been the signal to extinguish fire on the hearth and remain within doors. The practice was common in the middle ages. Polydore Virgil states that William the Conqueror introduced it into England as a measure of police. The obligation of extinguishing fire and light on the ringing of the curfew was abolished in England by Henry I. in 1100, but the evening bell itself was continued. We find entries in the municipal records of "ryngyng ye curfewe," "a man to ring the curfew," "new rope for the curfew bell," and so on, as late as the beginning of the 16th century. The evening bell and prayer bell, still tolled at stated hours in some places, had their origin in the *couvre feu*.

CURIÆ, the name of certain divisions of the people of ancient Rome. Romulus divided the whole population into 3 tribes, and each tribe into 10 curiæ. Although there were afterward 35 tribes, yet the number of the curiæ remained always the same. At first these curiæ possessed considerable political importance, but from the time when Servius Tullius instituted the centuries, their influence became slight. The place where a curia met was also called curia, and the place where the senate met was designated by the same name. In the Roman provincial cities, the name was applied to the body which administered the affairs of the town, and was responsible to the Roman government for the taxes. In the middle ages the name was also given to a solemn assembly of the counts and prelates of the empire.

CURIATII. See Horatii.

CURIO, C. Scribonius. I. A Roman publicist, a son of C. Scribonius the orator, died in 53 B. C. He was tribune of the people in 90 B. C., prætor in 82, and consul in 76. On the expiration of his consulship, he obtained the province of Macedonia, where he distinguished himself by waging successful war against the barbarians dwelling north toward the Danube. In 57 he returned to Rome and was appointed pontifex maximus, which office he held till his death. He had some reputation as an orator, and was at once a virulent enemy of Cæsar and an intimate friend of Cicero. II. A son of the preceding, was made tribune of the people in 50 B. C. On the outbreak of the civil war Cæsar sent him to act against the party of Pompey in Sicily. He succeeded in driving Cato out of that island, but venturing to cross over to Africa, he was defeated and slain.

CURLEW, a bird of the order *grallæ*, family *scolopacidæ*, subfamily *limosinæ* (which includes both curlews and godwits), and genus *numenius* (Lath.). The bill is long, slender, curved from the base, with sides compressed and grooved; the upper mandible projecting over the lower, and obtuse; wings long and pointed, the 1st quill the longest; tail short and even; tarsi long and slender; toes moderate, lateral ones unequal and united at their bases; hind toe long, slender, and partly resting on the ground; claws short and dull. There are nearly 20 species described, scattered over the temperate regions of the world in the winter, and going north in summer; they frequent the borders of the sea, and muddy and sandy shores, sometimes visiting moors and marshy plains, in search of worms, larvæ, crustacea, and mollusks, which they extract from the moist ground, often from under water, with their long bills; they also eat berries from the fields and woodlands. The nests are formed on the ground in holes, lined with grass, and the eggs are generally 4 in number. The long-billed curlew, or sickle-bill (*N. longirostris*, Wils.), is the largest of the American species, and may readily be distinguished from all others by the length of the bill, which is from 7 to 9 inches; the total length to end of claws is 29 inches, the extent of wings 40 inches, and the weight about 1¾ lbs. The general color of the plumage is pale reddish brown, the head and neck streaked with dusky; the upper part of the throat, and a band from the bill to the eye, light buff; above marked with blackish brown, tail barred with the same; abdomen plain yellowish red; feet bluish. Though found in the north, it is most abundant at the south, where it resides all the year and breeds; it feeds during the day in the marshes, retiring to the shores in large flocks at night; the favorite food is small fiddler crabs. They are easily shot, though rather tenacious of life, frequenting for some time the same resting place; they answer readily the fowler's call. The flesh is tough and fishy, and decidedly inferior to the smaller species. They are occasionally seen as far north as Boston. The Esquimaux curlew,

sometimes called dough-bird (*N. borealis*, Lath.), has a bill about 2¼ inches long, and tarsi 1⅝ inches; the length to end of claws about 17 inches, extent of wings 28 inches; weight ½ lb. The upper plumage is dusky brown, marked with numerous spots of light brownish yellow; a line of white from the bill to the eye; upper part of head brownish black, with streaks and a median line of grayish or yellowish white; throat white; neck and breast yellowish gray, with longitudinal marks and spots of dusky; abdomen dull yellowish white; flanks with brown bars; tail and its upper coverts pale grayish brown, with deep brown bars, and brownish white tip; primaries dark brown, the first shaft white with dusky tip. The females very closely resemble the males. In the New England and middle states this bird arrives from the north in the latter part of August, remaining through October, when it moves off to the south in flocks, going north again to breed in the spring. In Labrador its favorite food is the curlew berry, a small black fruit growing on a creeping shrub an inch or two high; in the open grounds in the vicinity of the sea, it feeds on insects, especially grasshoppers, seeds, worms, and berries. In the autumn they are very fat, hence their common name, and are considered great delicacies. They are not shy, running, squatting, and flying very much like a snipe. The Hudsonian or short-billed curlew (*N. Hudsonicus*, Lath.) is considerably larger than the last named species. Its bill is about 4 inches long; the total length to end of claws 21 inches, extent of wings 33 inches, and weight a little over a pound. The upper part of the head is deep brown, with a central and 2 lateral whitish lines; between the bill and eye, and behind the latter, brownish; the neck pale yellowish gray, with longitudinal brown streaks; chin grayish white; upper parts generally blackish brown, with numerous brownish white spots; wings and rump lighter; tail and its upper coverts with brown and yellowish gray bars, the former white-tipped; primaries brownish black; lower parts grayish white, the sides cream-colored and barred with grayish brown; shaft of first quill white. This species often associates with the sickle-bill, and arrives in large flocks on the New Jersey shore in May from the south; they soon move northward to breed; they return toward the last of August, remain a few weeks, and then proceed to the south to spend the winter. The habits and food are about the same as in the other species. The flight is high and rapid, and in their migrations accompanied by a constant whistling; they fly steadily, answer the sportsman's whistle readily, and are easily shot; they are considered excellent eating. Like the long-billed curlew, this species will linger around its wounded companions until many of a flock are killed; the latter, however, is much the rarest bird in most parts of the northern states. The largest of the European curlews is the *N. arquatus*, (Linn.), of the size of a capon; the general color is brown, with the edges of the feathers whitish; the rump is white, and the tail barred with white and brown. It is a well-flavored species. The whimbrel (*N. phæopus*, Linn.) is about half the size of the preceding, which it resembles in its plumage.

CURLING, a favorite Scottish game, played on the ice with large stones of a spherical form, flattened so that their length shall be equal to twice their thickness. They are carefully selected, so that they shall not be liable to break, have their under side polished, and vary in weight from 30 to 60 lbs. They have handles of wood or iron by which they are impelled over the ice. The path in which the stones move is called the *rink*, and may be from 30 to 50 yards long. At each end of the rink a mark or hole is made in the ice, called the *tee*. The players are divided into two parties, and each person endeavors either to leave his own stone as near the tee as possible, to remove those of the opposite party, or to guard those of his own side. When all have played, the one nearest the tee counts one, and the second, third, &c., if of the same side, count each one more. The side which first scores 31 wins.

CURRAN, John Philpot, an Irish orator, born at Newmarket, county of Cork, July 24, 1750, died at his residence in Brompton, a suburb of London, Oct. 14, 1817. His father was officer to a manorial court, and a person of great cultivation of mind, and his mother an accomplished woman, who made great efforts to procure for her son every possible advantage of education. After having been under the instruction of Nathaniel Boyse, the resident clergyman, who, as he himself says, made a man of him, and through a preparatory course at the free grammar school of Middleton, he entered Trinity college, Dublin, with a view of preparing himself for the church, but afterward determined to adopt the profession of the law, and in 1773 became a student of the Middle Temple, London, the Rev. Mr. Boyse having advanced him funds for that purpose. The succeeding year he married the daughter of Dr. Creagh, of Dublin, and in 1775 was called to the Irish bar. For some time he gave the rein to his generous social disposition. A club which he formed, under the name of the monks of St. Patrick, gathered together the leading liberals of the Irish metropolis. Here Curran shone in all his brilliancy. At the same time he was often in great pecuniary straits. He relates that one day, unable to pay his rent, he returned to the house in a state of despondency, when he found a brief awaiting him with 20 guineas. This brief was the commencement of his fortune, and was put in his way through the kindness of Lord Kilwarden, who, although differing with him in politics, continued his friend through life. His clients became so numerous that he was soon in easy circumstances. In 1782 he was returned to the Irish parliament as member for Kilbeggan. His attacks on the gov-

ernment soon led to duels, first with Mr. Fitzgibbon (afterward earl of Clare), then attorney-general, and next with Major Hobart, both ending without injury to either party. Step by step he rose in his profession, till he became the most popular barrister of his time. He had a dashing, fearless way that suited his auditory. His eloquence was thoroughly Irish. Rarely attempting to convince by argument, he always addressed himself successfully to the feelings. His style of metaphor was bold and original—often extravagant. In the cross-examination of witnesses he exceeded the recognized limits of forbearance, and was frequently bullying and insolent. On one occasion he so goaded Mr. St. Leger, a witness in the case of an assault by an Irish nobleman upon an aged priest, that he had to fight him. In persuasive powers Curran had no rival. His diction was fluent and charming, and he not unfrequently wound up his address by some solemn adjuration from Scripture. His voice was not naturally good, but he improved it by careful training. Personally he was the reverse of prepossessing, having a soft and boyish look. In the height of his prosperity he met with a severe domestic blow in the elopement of his wife. He obtained a verdict against the seducer, but would not touch the damages awarded. He even allowed the faithless wife a stipend, and went to London to see her when she was supposed to be on the point of death. Ireland was at that period in an excited political condition. The question of Catholic emancipation especially agitated the people. Curran advocated liberal principles in the house of commons, and defended liberal politicians in the courts of law. Although his talents in parliament were conspicuous, it was in the courts that he shone preëminent. There he made his finest political orations. His defence of the leaders of the rebellion of 1798 was his crowning effort; his most noted speeches being those in defence of Theobald Wolfe Tone, Major Rowan, Oliver Bond, the brothers Sheares, Jackson Finney, and Finnerty—in the latter of which he made a powerful appeal for the liberty of the press. During the sympathy excited for the French revolution Curran remained faithful to England, even while exhausting every element of opposition against her government. In 1800 the union of Ireland with Britain was accomplished. Curran, who had opposed it, viewed the event with despondency. Indeed, he had at one time decided to abandon the country and seek a new home in America; but other events, which followed rapidly, dispelled this idea. The peace of Amiens, in 1802, permitted him to visit the continent. On July 23, 1803, the rising under Robert Emmet took place. Curran had a deeper interest in this event than he himself was aware of, for an affection subsisted between Emmet and his daughter Sarah. The young man was executed, Sept. 20, 1803. During this year he made his celebrated speech in defence of Owen Kirwan. Political matters continued in much the same state until 1806, when the death of Pitt threw the power into the hands of Fox and the liberals. Curran was offered the post of master of the rolls in Ireland, which he accepted, although more desirous of the office of attorney-general. The duties of the office were unworthy of his abilities, and were hampered by petty jealousies. From this time his genius declined, and he sank into a state of hypochondria from which he never recovered. Occasionally the influence of travel or of music, in which he had some skill, would revive him, but only temporarily. In 1814 he exchanged his place for a pension of £2,700 per annum. He resided chiefly in his mansion at Brompton, where he enjoyed the acquaintance of Sheridan, Horne Tooke, Lord Erskine, the prince regent, and other notables. Godwin the novelist, and Moore the poet, were his devoted friends. In Sept. 1817, he wrote that he had "closed his accounts with hope." Afterward he complained of "a mountain of lead at his heart." Occasional flashes of his former wit lit up his decline. Speaking of a passing attack of apoplexy, he described it as "a runaway knock at death's door." On Oct. 8 he was seized with a second fit, of which he died in the following week. His "Speeches on the late very interesting State Trials" appeared in Dublin in 1808, and his "Speeches, with Memoirs by a Barrister," in London, 1817 (new edition, with memoir by Davis, 1845). His "Letter to the Rev. H. Weston" was published in 1819.—See also "Memoirs of the Life of Curran," by Alex. Stephens (1817); "Memoirs of the Legal, Literary, and Political Life of the late Rt. Hon. John Philpot Curran," by William O'Regan (1817); "Recollections of J. P. Curran and some of his Contemporaries," by C. Phillips (1818); "The Life of the Right Hon. John Philpot Curran," by his son William Henry Curran (1819).

CURRANT (*ribes*, Linn.), the name of a small, valuable, and well-known garden fruit, of which there are numerous varieties. Two principal species are commonly known, but there are several beside. The *R. rubrum* (Willd.), according to Persoon, grows spontaneously in Sweden, and in the northern parts of England, and is the origin of the garden kinds. It bears abundance of semi-transparent red berries in racemes, which diminish in size at the apex of the bunch. There is a white-fruited variety, more esteemed by some on account of its less acid juice. Great improvements have been made on these fruits by repeated experiments, and not only the plant has been rendered more robust, but the size of the berries has been increased. The London horticultural society's catalogue for 1842 gives a list of 10 sorts of the red and 3 sorts of the white currant, of which the red Dutch and the white Dutch, known also under many synonymes, have stood high in the estimation of practical gardeners. Knight succeeded in raising some improved kinds from seed, favorably known and bearing his name. Several lately introduced from France bear fruit of remarkable size and flavor; scarce-

ly any difference is to be seen in the size of the first and of the last berry on the raceme, and indeed they could be compared to miniature bunches of grapes. It has been thought that the red currant is a native of this country, an opinion founded on its identity with the *R. albinervium* of Michaux. According to the "Flora of North America," the red currant appears to be "abundant in our northern latitudes, agreeing in every respect with the European form." It occurs throughout Canada to the mouth of Mackenzie river, at Sault Ste. Marie, and at the sources of St. Croix river (Torrey and Gray). It has been noticed growing wild on the rocky banks of the Winooski, in Vermont. Josselyn, who wrote in 1672, makes mention in his "New England Rarities" of "red and black currants." The black currant (*R. nigrum*, Lam.), differing from the common currant in the great size of the plant, in smoother leaves, in flower and in fruit, also in possessing a powerful aromatic principle with proportionately less acidity, has by successive experiments become ranked with the most valuable of the smaller garden fruits. The variety known as the black Naples has larger berries than any other, and is considered the best. The fetid currant (*R. prostratum*, L'Héritier), with pale red and bristly fruit, exhaling, as well as the leaves, a disagreeable odor, grows on mountain sides and in cold woods at the northward, reaching as far as Lake Superior and the Rocky mountains. The thirsty wayfarer and the hunter, on meeting with its berries, find them not too unpleasant for refreshment. The *R. floridum* (L'Hér.), with rather large yellow-greenish flowers, and with smooth, black fruit, occurring in woods from Canada to Kentucky, is our native black currant, but is inferior in value to the European species. The Missouri currant (*R. aureum*, Pursh.) is remarkable for its early yellow blossoms, exhaling a delicious, spicy odor, and considered a highly ornamental shrub. The red flowering currant (*R. sanguineum*, Ph.), from western America, and abundant among rocks along the streams throughout Oregon, is a very beautiful shrub, bearing clusters of light crimson blossoms, which appear early in spring. Its fruit is insipid, but its flowers recommend it for the garden. Another, with flowers not so brightly colored (*R. malvaceum*, Sm.), has been noticed as a native of California. The genus *ribes*, embracing the gooseberries, comprises in North America something like 28 distinct species.—The propagation of the currant is easy, as it will grow in almost any garden soil, in the open sun or in the shade of fences, where the fruit is longer in ripening but still sure. The best mode to be pursued is, never to allow suckers taken from the roots of old plants to be used for new planting out; but to employ well ripened, straight, and stout shoots, removing all the buds or eyes from the lower portions which are to be inserted in the soil, which will prevent future suckers from springing up around the stem. Sometimes, after the stem has been trained upright for 2 or 3 feet, the branches are spread thinly upon a low espalier; or, in case this is not used, a thin, spreading head is carefully grown. All superfluous wood, as it makes its appearance, is removed, and about midsummer the ends of the fruit-bearing branches are pinched off, in order to allow the fruit to swell and increase. But the currant will reward the least degree of attention that is given to it. The juice of the currant contains sugar and malic acid, to the presence of which is owing its pleasant flavor. Currant wine is considered a valuable beverage, and for preserves, tarts, or for the dessert, currants are especially esteemed. When freshly gathered they are refrigerant and very grateful to the palate. An excellent jelly is prepared from them, and for other domestic purposes their reputation is well known. The fruit of the black currant is far less esteemed, indeed to many persons is positively disagreeable. A jelly made of it is used as a remedy for hoarseness or sore throat, and lozenges made of the berries, and especially of their skins, are of much service in pectoral complaints. A wine is made in Russia from the black currant berries, and in Siberia the leaves, dried and mixed with souchong, are made into a drink resembling in flavor green tea. The fruit, leaves, and wood are tonic and stimulant. We have seen the dried fruit of the better garden sorts used in making puddings which possessed much merit.—The word currant is said to be a corruption of Corinth, the original place whence the small raisins were brought known as the currants of commerce. The Ionian islands, Greece, and Turkey are the principal currant-exporting countries, and directly from those countries, and indirectly through England, not less than about 2,500,000 lbs., valued at about $150,000, were imported into the United States in the year ending June 30, 1857.

CURRENCY. See MONEY.

CURRENT RIVER, an affluent of Black river, Arkansas, rises in Texas co., Mo., and has a S. W. course of over 250 m. It is navigable by flatboats, and abounds with excellent fish. Jack's Fork is its principal branch.

CURRENTS. See ATLANTIC OCEAN.

CURRIE, JAMES, a Scottish physician, born at Kirkpatrick-Fleming, Dumfriesshire, May 31, 1756, died at Sidmouth, Devonshire, Aug. 31, 1805. In early life he went to Virginia, with a view of following commercial pursuits, but returning after the breaking out of the American war, he commenced the study of medicine at Edinburgh, was graduated at Glasgow in 1780, and in the following year began to practise in Liverpool. He was very successful in applying affusions of cold and tepid water to the cure of disease, and his great work on this subject, "Medical Reports on the Effects of Water, cold and warm, as a Remedy in Febrile Diseases," appeared in 1797, a 2d volume in 1804, and a 5th edition in 1814. Beside several other medical works, he wrote "A Letter, Commer-

cial and Political, to William Pitt," under the assumed name of Jasper Wilson, which attracted much attention. In 1800 he published an edition of the works of Robert Burns, in 4 vols., for the benefit of the poet's family. This edition has been frequently reprinted. It contains an account of the life of Burns, and a criticism on his writings, to which are prefixed "Some Observations on the Character and Condition of the Scottish Peasantry."

CURRITUCK, a N. E. co. of N. C.; area estimated at 200 sq. m.; pop. in 1850, 7,236, of whom 2,447 were slaves. It borders on Va., and embraces within its limits several islands separated from the mainland by Currituck sound. The surface is level, and the soil sandy. In 1850 the productions were 292,593 bushels of corn, 66,332 of sweet potatoes, and 20,382 lbs. of butter. The county was named from a tribe of Indians who once possessed the land. Capital, Currituck Court House.

CURRY, Daniel, an American clergyman and author, born in Peekskill, N. Y., Nov. 26, 1809, was graduated in 1827 at the Wesleyan university at Middletown, Conn., and was in the same year elected principal of the Troy conference academy, where he remained several years. In 1841 he removed to Georgia, where he was regularly inducted into the ministry of the Methodist Episcopal church, and was stationed successively at Athens, Savannah, and Columbus. When the difficulties arose on the subject of slavery, which finally resulted in a division of the church, he connected himself with the northern branch, and entered the New York conference. After having been stationed in the cities of New York, New Haven, Brooklyn, and Hartford, he officiated for 3 years as president of the Indiana Wesleyan university. He then returned to Brooklyn, and is now (1859) pastor of the Methodist church in Middletown. He has contributed largely to various magazines of the day, and among his works are his "Life of Wycliffe" and "Metropolitan City of America." He has also published an edition of Southey's "Life of Wesley," with notes.

CURRY POWDER, a powder used in cooking, prepared in the East Indies. The ingredients in its manufacture are turmeric, coriander, black pepper, 4 oz. each; fenugreek, 3 oz.; ginger, 2 oz.; cummin seed, ground rice, 1 oz. each; cayenne pepper and cardamoms, ½ oz. each. Curry powder is subject to extensive adulteration, and with very pernicious ingredients, red lead being frequently detected in it. As this is a highly poisonous oxide, the quantity taken in curry powder at a meal has been known to produce a serious effect. It is therefore a safer, as well as a more economical plan, to purchase the materials, and prepare the article.

CURRYING, the art of finishing tanned leather to give it the smoothness and pliancy it requires for most of its uses. The skin is first softened by soaking it in water, and it is then beaten with a mace or mallet upon a hurdle or lattice-work support. It is next laid over a plank called a beam, which projects at a slant from the floor, and the workman, leaning over the end of this, and against the skin to hold it in its place, shaves off the inequalities on the flesh side with a broad blade, called a head knife or beam knife, the edge of which is turned over. This instrument is held firmly in both hands; and as it is used, the currier continually examines with his fingers the effect produced, and moves the skin to bring all parts of it under its action. After it is sufficiently shaved, the skin is thrown into cold water, and well scoured upon a stone slab, the flesh side being laid next the stone, and the grain or hair side well rubbed with a tool of metal or stone called a stretching iron, which is held in both hands. The whitish matter (bloom) gathered from the tan pit is thus forced out, and the inequalities of thickness still more reduced. Tools of several kinds are employed for scraping and dressing down the irregularities of the surface—sometimes a circular knife, among others, shaped like a bowl, the bottom being open for the insertion of the hand. By these operations the skin is softened and prepared for the dubbing (daubing) process. Each side of it is well rubbed with an oily compound made by boiling cod oil with the skins of sheep; and the leather is then hung up to dry. Either before or after this it is subjected to the action of rubbing with the pommel or graining board, an instrument shaped somewhat like a brush, with a leather strap on the back to give a secure hold for the hand slipped under it. It is entirely of hard wood, the under or rubbing surface made with transverse grooves like a crimping board. The leather is folded over, leaving the flesh side out, and is strongly rubbed with the pommel. It is then spread out, leaving the other side exposed to receive a similar application. By this operation the flexibility is greatly increased. After this graining process, the leather is in good condition for storing and keeping till wanted for sale; or, after delicately shaving the flesh side with a very sharp knife, it may be immediately submitted to the process of waxing. A color composed of oil and lampblack is well rubbed in on the flesh side with a hard brush till the surface is thoroughly black; upon this is applied with a brush or sponge a coat of stiff size and tallow, and when dry it is rubbed with a broad smooth lump of glass. The sizing and rubbing are then repeated. Leather thus treated is distinguished either by the name "waxed," or "black on the flesh," and is used for the uppers of men's boots and shoes. If curried on the other side, it is called "black on the grain," and this sort is used for the uppers of ladies' shoes. The treatment is the same for both up to the waxing. To the leather to be made black on the grain is applied a solution of copperas, the effect of which is to produce a black dye by the union of the iron of this salt with the gallic acid of the tan. It is then rubbed with a brush dipped in stale urine, and when dry the application of oil and lampblack is

made; and when this is dry another application of the copperas with rubbing. After this it undergoes the treatment with the pommel again, and several other processes of rubbing, polishing, and dubbing or oiling.

CURTIS, Benjamin Robbins, an American jurist, born in Watertown, Mass., Nov. 4, 1809, was graduated at Harvard college in 1829. He was admitted to the bar in 1832, and commenced the practice of the law at Northfield, Mass., but soon removed to Boston, where he took a high rank and secured an extensive business. He was remarkable for the extent and readiness of his legal attainments, the clearness and accuracy of his statements, and the vigorous grasp of his logic. Upon the death of the late Judge Woodbury, he was appointed a judge of the supreme court of the United States in September, 1851. This office he held till the autumn of 1857, when he resigned it. Since his retirement from the bench, he has resumed the practice of his profession in Boston. Few distinguished lawyers in our country have devoted themselves so exclusively to their profession as Judge Curtis. He was for one or two years a member of the house of representatives in Massachusetts, but has taken very little part in politics.—George Ticknor, an American lawyer and juridical author, younger brother of the preceding, born in Watertown, Mass., Nov. 28, 1812, was graduated at Harvard college in 1832. He was admitted to the bar in 1836, and has ever since been engaged in the practice of the law in Boston. He has made several valuable contributions to the literature of his profession. He is the author of treatises on the "Rights and Duties of Merchant Seamen" (1844); on the "Law of Copyright" (1847); and on the "Law of Patents" (1849). These are all works of acknowledged merit. He has also compiled a volume of "Equity Precedents," a digest of English and American admiralty decisions, and 2 vols. of the series of digests of the reports of the United States, published by Little, Brown, and co., were prepared by him. He has also published (1854) the first volume of a work entitled "Commentaries on the Jurisprudence, Practice, and Peculiar Jurisdiction of the Courts of the United States," which was highly commended by Chief Justice Taney. But the work by which he is best known is a "History of the Origin, Formation, and Adoption of the Constitution of the United States," the first volume of which was published in 1855, and the second in 1858. This is a work of careful and patient research, candid political judgment, and great clearness of style. Mr. Curtis served for 2 or 3 years as a member of the Massachusetts house of representatives, but he has allowed politics to interfere but little with the labors of his profession, and his historical and constitutional investigations.

CURTIS, George William, an American author, born at Providence, R. I., Feb. 24, 1824. His father, George Curtis, was from Worcester, Mass.; his mother was a daughter of James Burrill, a U. S. senator from Rhode Island, who distinguished himself in opposition to the Missouri compromise. Mr. Curtis received his early education in Mr. Green's school at Jamaica Plain, Mass. When he was 15 his father removed from Providence to New York, where he began an apprenticeship to trade in the counting-house of a dry goods importer. He remained in this position, however, only a year. In 1842 he went with his elder brother to reside with the association for agriculture and education at Brook Farm, in West Roxbury, Mass., where he passed a year and a half in study and agricultural labor; after which, attracted by the cultivated and intellectual society at Concord, Mass., in whose circle Mr. Emerson and Mr. Hawthorne were included, Mr. Curtis, with his brother, spent 18 months there, living with a farmer, and both taking part regularly in the ordinary work of the farm; and then 6 months in tilling a small piece of land on their own account. In 1846 Mr. Curtis went to Europe, and after a year in Italy entered the university of Berlin, where he remained a few months, and witnessed the revolutionary scenes in that city in the spring of 1848. The 2 subsequent years he spent chiefly in travel through central and southern Europe, and in Egypt and Syria. In 1850 he returned to the United States, and in the summer of that year published his first book, the "Nile Notes of a Howadji." He soon after joined the editorial staff of the "New York Tribune," and in the summer of 1851 wrote a series of letters to that journal from various watering places, which were afterward collected in a volume, under the title of "Lotus Eating." His second book, however, was the "Howadji in Syria," published in 1852. In the autumn of 1852 "Putnam's Monthly" was commenced in New York, of which Mr. Curtis was one of the original editors, and with which he continued connected till the magazine was merged in another, and virtually ceased to exist. "Prue and I," which was published in 1856, was made up from some of his contributions to that periodical. The second publishers of "Putnam's Monthly" were Dix, Edwards, and co., and in this house Mr. Curtis was a silent partner, pecuniarily responsible, but taking no part in its commercial management. In the spring of 1857 the house was found to be insolvent, and he then, in connection with Mr. Miller, who had been its printer, assumed its assets and liabilities, in the hope of saving the creditors from loss. The attempt was unsuccessful, and he was compelled in a few months to abandon an enterprise in which his private fortune had been entirely sunk. As a lyceum lecturer, upon which field of labor Mr. Curtis entered in 1853, he has met with great success. He delivered a poem at the university of Rochester in 1853, and another before a society in Brown university the year following. His orations on similar occasions have been numerous. In the presidential canvass of 1856 he enlisted with great zeal as a public speaker on behalf of the republican party.

In the winter of 1858 he appeared as the advocate of the rights of woman, in a lecture entitled "Fair Play for Women." To the current literature of the day he has been a constant contributor since 1853, through "Harper's Monthly," as well as through "Putnam's Monthly," as long as it existed, and through "Harper's Weekly," newspaper, since the autumn of 1857.

CURTIUS, Ernst, a German philologist and archæologist, born in Lübeck, Sept. 2, 1814, became professor in Berlin in 1843, was tutor of Frederic William, the son of the present regent of Prussia, until 1850, and appointed in 1856 professor in Göttingen, as successor of the famous Herrman. He has written largely on Grecian antiquities. Among his more recent works is *Die Ionier vor der Ionischen Wanderung* (1855).—His brother, Georg, born April 16, 1820, officiating since 1851 as professor in Prague, has written several philological works, including a Greek grammar for the use of colleges (2d ed. Prague, 1855).

CURTIUS, Marcus, a Roman hero, who lived about the middle of the 4th century B. C., and who is said to have sacrificed himself for the good of his country. The legend which relates this event is in substance as follows: An earthquake once happening at Rome, a large portion of the area of the forum sank down, and a vast chasm appeared there. All attempts to fill it up were vain, and the city was smitten with consternation, especially as the haruspices had declared that it could only be filled by casting into it that on which the greatness of Rome depended. While every one was hesitating and doubting as to the meaning of the haruspicial declaration, the heroic Marcus presented himself, and proclaiming that Rome contained nothing more indispensable to her greatness than a valiant citizen fully accoutred for battle, he offered himself as a victim; and, having arrayed himself in complete armor and mounted his war horse, he galloped into the abyss. Then the earth closed, the chasm vanished, and the forum resumed its wonted aspect. But the place of the chasm, and of the sacrifice of Marcus, was ever after called *Lacus Curtius*. Other versions of the legend are given by different authors, but the above has obtained the greatest currency.

CURTIUS RUFUS, Quintus, the Roman historian of Alexander the Great. Respecting his life and the age in which he lived we have no accurate information. Some critics make him contemporary with Vespasian, and some with Constantine, but it is probable that the former are nearer the truth. The history of Curtius is entitled *De Rebus Gestis Alexandri Magni*. It consisted originally of 10 books, but the first 2 have perished, and the 8 that remain are not by any means perfect. It is not a good historical authority. The best edition is that of Zumpt (Berlin, 1849).

CURULE CHAIR, a state chair among the ancient Romans, permission to use which was a mark of high honor, and only granted, under the republic, to the dictator, consuls, prætors, censors, chief ædiles, the flamen dialis, and those deputed by the dictator to act under himself. In the times of the empire this honor was granted to others. The magistrates entitled to use this chair were called curule magistrates, and when they went to council, the chair was borne on a chariot (*currus*), whence its name. At first it was only adorned with ivory, but in later times it was overlaid with gold.

CURVE, or Curved Line, in geometry, a line which continually and continuously changes its direction. In the higher geometry, a curve is a line in which the coördinates of each point fulfil the same laws. The circumference of a circle is the simplest of all curves. The laws which each point in it must obey are various. One is that each point is equally distant from the centre; another that each part of the line is equally curved, &c. The circle is taken as the measure of curvature. The circle which would exactly fit any curve at any point is called the circle of curvature at that point, and its radius, the radius of curvature. A law by which this radius increases and diminishes in going to different points is usually considered the most vital law of the curve, or intrinsic equation.

CURZON, Paul Alfred de, a French painter, born Sept. 7, 1820. He excels chiefly in landscape painting, has explored the Morea in company with Edmond About and Charles Garnier, and has executed many good pictures, especially those of the Acropolis of Athens, and the shores of the Cephissus, which were favorably noticed at the universal exhibition in Paris in 1855. He also received a second medal in 1857.

CUSH, the name of the eldest son of Ham, as well as of a southern region of the scriptural world, which is rendered Ethiopia by the Septuagint, the Vulgate, and by almost all other versions of the Hebrew Bible, and *Mohrenland*, or land of the blacks, by Luther. There can be no rational doubt that Ethiopia, in its more common and limited sense, was designated by that appellation in Hebrew, though Bochart has contended for its meaning exclusively southern Arabia. Ezekiel (xxix. 10) speaks of it as lying beyond Syene, which perfectly agrees with the classical definition of the boundaries of Ethiopia; Mizraim (Egypt) and Cush are often connected by the prophets, and mentioned together in the Psalms (lxviii. 31). The Cushites appear together with other African nations in historical relations; their black complexion is alluded to in the Bible as well as in the Mishna. But whether Cush did or did not include any other region in the world known to the Hebrews, especially southern Arabia, is a question which has elicited a great deal of ethnological controversy. Michaelis and a number of other critics defend the affirmative. Gesenius maintains the negative. The former opinion is strengthened by a number of scriptural passages in which Cush appears together with Arabian tribes, by its being rendered Arabia in the Chaldee paraphrase of Jonathan, and by the existence of a

tribe called Beni Chusi in Yemen, according to Niebuhr. We find, beside, the land of Cush compassed by the river Gihon (Gen. ii. 13), and Cush as the father of Nimrod, who founded empires in Asia; the same name is connected by Ezekiel with Elam or Susiana, which again agrees with the classical names of Cissians and Cossæans given to the inhabitants of the latter country, and with its modern name, Khusistan. The Himyarites, an ancient people of southern Arabia, are styled by Syrian writers both Cushæans and Ethiopians. The classical term Ethiopia, too, comprised many distant and distinct nations, having in common only their sun-burnt complexion. Homer calls them "a divided race, the last of men, some of them at the extreme west, and others at the extreme east." Strabo says nearly the same. Herodotus speaks of an eastern or Asiatic, and a western or African Ethiopia. The prevalent opinion of the latest ethnological and biblical scholars is, therefore, that Cush in its limited meaning designates Ethiopia, but is also the name of several other Asiatic regions situated along the shores of the southern ocean, and inhabited by people of the Hamitic family. "Recent linguistic discovery," says George Rawlinson ("Translation of Herodotus," book i. essay xi.), "tends to show that a Cushite or Ethiopian race did in the earliest times extend itself along the shores of the southern ocean from Abyssinia to India. The whole peninsula of India was peopled by a race of this character, before the influx of the Aryans; it extended from the Indus along the sea-coast through the modern Beloochistan and Kerman, which was the proper country of the Asiatic Ethiopians; the cities on the northern shores of the Persian gulf are shown by the brick inscriptions found among their ruins to have belonged to this race; it was dominant in Susiana and Babylonia, until overpowered in the one country by Aryan, in the other by Semitic intrusion; it can be traced, both by dialect and tradition, throughout the whole south coast of the Arabian peninsula; and it still exists in Abyssinia, where the language of the principal tribe (the Galla) furnishes, it is thought, a clue to the cuneiform inscriptions of Susiana and Elymais, which date from a period probably a thousand years before our era."

CUSHING, Caleb, an American statesman and jurist, born in Salisbury, Essex co., Mass., in Jan. 1800. He belongs to an old colonial family, which has been largely represented in offices of public service. At the age of 17 he was graduated at Harvard college, and for nearly 2 years subsequent performed the duties of tutor of mathematics and natural philosophy in that institution. Meanwhile he entered upon the study of law, and after the unusual preparatory period of 5 years, was admitted to the bar, commencing practice at Newburyport. Although he attained high professional success, he continued to give a part of his attention to literary studies, and became prominent among the contributors to the "North American Review," by his papers upon historical and legal topics. The political life of Mr. Cushing commenced in 1825, when he was elected a representative from Newburyport in the lower house of the Massachusetts legislature. In 1826 he was elected to the state senate. At the beginning of his public life he was a member of the then republican party. In 1829 Mr. Cushing visited Europe on a tour of pleasure, and remained abroad nearly 2 years. The fruits of this tour were his "Reminiscences of Spain," a collection of miscellanies published in 1833, which indicated a minute acquaintance with Spanish history and literature. To this succeeded, in the same year, his elaborate and learned "Historical and Political Review" of the revolution of Three Days in France, and of the consequent events in other European nations. A portion of this work, which was issued in 2 volumes, had previously appeared in the "American Annual Register." In 1833 Mr. Cushing resumed political life, and was again elected a representative from Newburyport to the Massachusetts legislature, in which position he continued 2 years. In 1835 he was elected from the Essex north district of Massachusetts a representative to congress, in which body he served for 4 consecutive terms. Having supported John Quincy Adams for the presidency, Mr. Cushing thenceforward, until the administration of President Tyler, remained a member of the whig party. At that time, however, in company with Mr. Wise of Virginia and others, abandoning his former political associates, he supported the administration, and has ever since been connected with the democratic party. His congressional career was distinguished by unusual application to public service, as well as by eloquence and parliamentary accomplishments of a high order. His influence was felt, not less in the labors and deliberations of the committee room, than in the debates of the house, as is attested by the numerous and voluminous reports which he had occasion to prepare and submit for its legislative action. In 1843 President Tyler nominated Mr. Cushing as secretary of the treasury, but the nomination was rejected by the senate. The appointment of commissioner to China was then tendered him, and in the summer of 1843 he proceeded to that country. In 1844 he negotiated the first treaty of the U. S. government with the emperor of China. On his return home he was again elected to represent Newburyport in the state legislature, and during the session of 1847 became conspicuous by his advocacy of the Mexican war, a measure not at all favored by a majority of the people of the state. A bill to appropriate funds to equip the Massachusetts regiment of volunteers having been defeated in the legislature, Mr. Cushing furnished the requisite sum from his own means. He was then appointed colonel of the regiment, and in the spring of 1847 accompanied it to the Rio Grande in Mexico. Soon after his arrival at the seat of war, where he was attached to the army under command of Gen. Taylor, he received the appointment of brigadier-general. During the war he was one of the 3 officers con-

stituting the board of inquiry for the investigation of the charges against Generals Scott, Pillow, and Worth. In 1847, while still in Mexico, he was nominated by the democratic party of Massachusetts as its candidate for governor, but was defeated. In 1850, for the 6th time, he represented Newburyport in the legislature of his native state, where he was active in opposing the election of Mr. Charles Sumner as U. S. senator, and the coalition between the free-soil and democratic parties. In 1850 he was elected as the first mayor of the city of Newburyport, and in the year following was reëlected for a second term. In 1852 Mr. Cushing was appointed a justice of the Massachusetts supreme court, a position which he filled with marked ability until March, 1853, when he was invited by President Pierce to fill the office of U. S. attorney-general, from which he retired, March 4, 1857. Notwithstanding the number and complexity of novel questions (arising partly from the expansion of the national domain) submitted for the attorney-general's consideration, the duties of the office were never, on the whole, more thoroughly and ably performed than by Mr. Cushing. The opinions given by him as legal adviser to the cabinet have been published, and although more voluminous and covering a more extended variety of topics, they are in no respect surpassed by those of his official predecessors. In 1857, 1858, and 1859 he again served in the legislature of Massachusetts. In addition to his speeches in congress and at the bar, Mr. Cushing has delivered many addresses on occasions of literary and political festivity, and is the author of various published letters, elaborately discussing the political questions of the time.

CUSHING, Luther Stearns, an American jurist, born in Lunenburg, Mass., June 22, 1803, died in Boston, June 22, 1856. He became clerk of the Massachusetts house of representatives in 1832, judge of the court of common pleas in 1844, and after 4 years on the bench became reporter to the supreme court. In the last capacity he published 8 vols. of reports. He was a leading editor for some years of the "Jurist and Law Magazine," and left several able works on jurisprudence, including "Rules of Proceedings and Debates in Deliberative Assemblies" (18mo. 1854); "Introduction to the Study of Roman Law" (12mo. 1854); "Law and Practice of Legislative Assemblies in the United States" (8vo. 1855).

CUSHING, Thomas, LL.D., lieutenant-governor of Massachusetts, born in Boston in 1725, died Feb. 19, 1788. He represented the city of Boston in the general court, became speaker of that body in 1763, and so warmly espoused the cause of his country in the disputes with Great Britain that Dr. Johnson, in his "Taxation No Tyranny," made this remark: "One object of the Americans is said to be, to adorn the brows of Mr. Cushing with a diadem." He was a member of the 1st and 2d congresses, and afterward of the council of his own state. On the adoption of the present constitution he left the bench of Suffolk co., where he had filled the office of judge of the courts of common pleas and of probate, and was elected lieutenant-governor, a station which he retained until his death.

CUSHING, William, LL.D., an American jurist, born in Scituate, Mass., in March, 1733, died in 1810. He was graduated at Harvard college in 1751, and in 1772 succeeded his father, John Cushing, as justice of the superior court of Massachusetts. He became chief justice 5 years later, and on the organization of the federal government in 1789 was raised by President Washington to the bench of the U. S. supreme court.

CUSHMAN, Charlotte Saunders, an American actress, born in Boston, Mass., July 23, 1816, the oldest of a family of 5 children by a 2d marriage. In consequence of the bankruptcy of her father she was called upon at the age of 12 to contribute to the family support. Possessing a fine voice and much musical taste, she had already acquired some local reputation as a vocalist, when she was engaged to sing in a concert with Mrs. Wood, who declared her voice to be the finest contralto she had ever heard, and advised her to cultivate it for the stage. Against the advice and wishes of her friends she resolved to adopt this course, and made her *début* at the Tremont theatre, Boston, April 18, 1835, as the Countess, in the English adaptation of Mozart's *Nozze di Figaro*. Her success was such that an engagement was procured for her to sing in English opera at New Orleans. Scarcely had she arrived there when her voice failed her under the effect of a sudden change of climate and of an unwise attempt to convert it into an available soprano. In this emergency she resolved to become an actress, and under the tuition of Mr. Barton, an actor who proved a sincere friend, studied the part of Lady Macbeth, in which to the surprise of all she made her appearance with complete success. The piece was repeated many nights, and she returned to New York with considerable reputation for histrionic ability. She accepted a 3 years' engagement at the Bowery theatre, but after performing a week to large audiences, she was prostrated by fever, the result of over-excitement and exertion, and during her illness the theatre, and with it her entire theatrical wardrobe, was destroyed by fire. After an interval of several months she accepted an engagement as stock actress in the Park theatre, and for 3 years appeared in a great variety of parts, thus perfecting herself in stage business and acquiring the versatility for which she afterward became distinguished. During this period she assisted her younger sister, Mrs. Merriman, better known as Miss Susan W. Cushman, to make her *début* on the stage, and afterward appeared with her for several seasons at Philadelphia and New York. For the purpose of encouraging and improving the young actress, and of obtaining for her prominent female characters, Miss Cushman was accustomed to take the chief male parts in the plays in which her sister

appeared. In this manner they performed in "London Assurance" in New York for upward of 90 nights; and for one season in Philadelphia they played all the principal characters. Miss Cushman afterward undertook the direction of one of the Philadelphia theatres, which she retained until invited by Mr. Macready in 1844 to accompany him on a professional tour in the northern states, in the course of which she undertook the higher range of tragic parts with great success. In 1845 she went to England, and, unknown and unheralded, made her first appearance before a London audience, at the Princess's theatre, as Bianca, in Milman's tragedy of "Fazio." Her reception was enthusiastic, and for 84 nights she appeared in a variety of characters, including Lady Macbeth, Julia in the "Hunchback," Mrs. Haller, Beatrice, Lady Teazle, Rosalind, and Juliana in the "Honeymoon." Her sister having joined her, they acted together for several years at the Haymarket theatre in London and in the chief provincial towns of Great Britain. In 1849 she revisited the United States, and, in addition to her ordinary characters, assumed that of Meg Merrilies, in the play of "Guy Mannering"—a striking personation, and one which she may be said to have created. After another professional tour in England she returned to America, and having accumulated a fortune by her profession, took a formal leave of the American stage. She subsequently acted a round of engagements in England, and appeared again in the United States in 1857 and '58, after which she returned to Rome, where she had previously resided. As an actress, particularly in the higher walks of the serious drama, Miss Cushman ranks with the most eminent living, and in her Shakespearean characters is distinguished for a rigid adherence to the letter as well as the spirit of the text.—Her sister Susan, who attained considerable popularity in such parts as Ophelia, Juliet (which she acted to her sister's Romeo for upward of 200 nights in England), Olivia, &c., was married in March, 1848, to Dr. James S. Muspratt of Liverpool, where she now resides.

CUSHMAN. I. Robert, one of the founders of Plymouth colony, born in England about 1580, died in 1625. He joined the nonconformist exiles at Leyden, and in 1617 was sent by them to London with John Carver, as their agent to negotiate with the Virginia company for leave to settle within their domain in North America, and to petition King James for "liberty of conscience there." Not gaining the last point, which was the chief desire of the exiles, he returned to Leyden, after an absence of about 6 months. In the latter part of the same year he, with the same colleague, was again despatched with written terms from the Leyden Congregational church, but gained no better result, for the company was now distracted by dissensions among its officers, so that "no business could well go forward." In 1619 Mr. Cushman was sent the 3d time on the same embassy (associated with Elder William Brewster), and a patent was finally obtained in the name of John Wincob, which, however, was not used, as that person did not emigrate. In 1620 he was despatched the 4th time to London, with Carver and Martin as his associates, to receive money and provide for their embarkation. The "Merchant Adventurers" of London now began to withdraw their means and promises, and insisted upon two stringent alterations in the terms of their contract previously agreed upon with his associate. Cushman assented to them, a step which gave temporary dissatisfaction to many of his friends, though they afterward perceived that it saved the expedition and their ventures in it from utter failure. He procured the Mayflower, a pilot, &c., and finally sailed in her, as "assistant governor" to the passengers, from Southampton, Aug. 5, 1620, in company with the Speedwell. Eight days out, the Speedwell proving leaky, both vessels put into Dartmouth for repairs, and remained there 8 days. They took their 2d departure Aug. 21, and in 3 days the Speedwell was reported leaking again; both vessels then put into Plymouth, when the Speedwell was dismissed as unseaworthy, and her company compelled to remain. Mr. Cushman was appointed to the care of those left ashore, and followed in the next vessel, the Fortune, 55 tons, bringing most of them and others, and reaching New Plymouth, Nov. 9, 1621. On Dec. 12 he preached in the "common house" of the little colony the first sermon in America that was printed: "On the Sin and Danger of Self-Love"—a practical, far-seeing discourse, abounding in wisdom, and enriched with very many illustrations and examples drawn from sacred history, evidently written to allay any dissatisfaction that might have been apprehended among the colonists. He sailed for England the next day, in the same vessel by which he came, which was captured by the French, plundered, and detained 2 weeks on their coast. After his arrival he wrote and published an eloquent vindication of the colonial enterprise, and appeal for Christian missions to the American Indians; which was the first published argument for English emigration to this country. He continued to reside in London, acting as agent for the colonists. In 1623, he with Edward Winslow, envoy from New Plymouth, procured from King James, through Lord Sheffield, a charter for territory on Cape Ann. Early in 1625, while preparing to emigrate thither by the next ship, to join his son, and make New Plymouth his permanent residence, he died. II. Thomas, son of the foregoing, born in England in 1608, died at Plymouth, Dec. 11, 1691. He came with his father to New Plymouth in the Fortune, Nov. 9, 1621, and was left in the care of Gov. Bradford, in whose family he lived till manhood. He married Mary, 3d child of Isaac Allerton, who was the last survivor of the Mayflower passengers, and who died in 1699, aged 90. His life and death are best depicted in the following extract from the Plymouth 1st church records, vol. i.:

"1691. It pleased God to seize upon our good Elder, Mr. Thomas Cushman, by sickness, and in this year to take him from us. He was chosen and ordained Elder of this Church, April 6, 1649; he was neere 43 yeares in his office, his sicknesse lasted about eleven weeks; he had bin a rich blessing to this church scores of years, he was grave, sober, holy and temperate, very studious and solicitous for the peace and prosperity of the church, and to prevent and heale all breaches: He dyed, December 11, neare the end of the 84th yeare of his life; December 16: was kept as a day of humiliation for his death,—the Pastor prayed and preached. Mr. Arnold and the Pastor's 2 sons assisted in prayer; much of God's presence went away from this church when this blessed pillar was removed.

"A liberal contribution was made that fast day for the Elder's widow, as an acknowledgement of his great services to the church whilst living.

"August 7, 1715. A contribntion was moved and made, both by the church and congregation, to defray the expense of Grave Stones sett upon the grave of that worthy and useful servant of God, Elder Thomas Cushman; the whole congregation were very forward in it."

A massive granite monument to the memory of these 3 Cushmans was erected at Plymouth by their numerous descendants, and publicly consecrated, Sept. 16, 1858.

CUSK, a fish belonging to the cod family or *gadidæ*, and to the genus *brosmius* (Cuv.), characterized by an elongated body, a single dorsal fin extending the whole length of the back, fleshy ventral fins, and one barbel at the chin. The American cusk, which is considered specifically distinct from the European, is the *B. flavescens* (Lesueur); the color varies from brownish with yellowish sides, to whitish with brownish patches; the immature fish is of a uniform dark slate color, sometimes with transverse yellow bands; the dorsal, caudal, and anal fins are bordered with bluish black, and edged with white; the dorsal and anal are continued to the base of the tail. The length of the fish varies from 2 to 3 feet and more, one of the first dimensions weighing about 4 lbs.; it is taken generally on the middle bank, with the hook, by the deep water cod-fishers. In the spring it is seen in Boston market, when it is less esteemed than cod, but in the winter it commands a higher price; as a fresh fish it is considered a delicacy, and salted is generally preferred to cod. It is found along the shore of the British provinces, and even to high latitudes. The European species, *B. vulgaris* (Cuv.), called torsk or tusk, is also a northern fish, occurring plentifully among the Shetland islands, where it forms a considerable article of trade; it is caught, salted, and dried in the same manner as cod; it is common on the coasts of Norway, Iceland, and the Faroe islands. It resembles very much the *B. flavescens*, and the two are considered by some as varieties of one species.

CUSP (Lat. *cuspis*, a spear-point), in astronomy, a horn or point of the moon, or of any other luminary. In geometry, it denotes the point or corner in which two branches of the same or of different curves meet. In architecture, it is applied to the spear-shaped ornaments which terminate the internal curves of trefoiled and quatrefoiled Gothic arch windows. In astrology, it denotes the first point of each of the 12 houses in a scheme of the heavens.

CUST, Sir Edward, an English major-general, master of ceremonies at the court of Queen Victoria since 1847, born in London in 1794, served in the army under Wellington, and was for several years, until 1832, a member of the house of commons.

CUSTINE. I. Adam Philippe, count de, a French general, born in Metz, Feb. 4, 1740, guillotined in Paris, Aug. 29, 1793. He served with distinction in the 7 years' war, and in the American war of independence under Washington. On his return to France he was appointed governor of Toulon, and in 1789 was elected by the nobility of Lorraine as deputy to the states-general. He was a partisan of the revolution, but his noble birth and associations with the nobility made him a constant object of suspicion to the republicans of plebeian origin. He returned to military life, and was in June, 1792, appointed commander-in-chief of the French army on the lower Rhine. He took possession of Landau, Spire, Worms, Mentz, and Frankfort-on-the-Main; but suddenly evacuated the German towns, and withdrew to Alsace. This gave umbrage to the leaders of the convention; but he succeeded in vindicating himself, and received the command of the northern army. However, he was finally accused of treason, sentenced to death on Aug. 28, 1793, and guillotined on the following day, but asserted to the last his loyalty to the principles of the revolution. A few months later, his son, Renaud Philippe, his aide-de-camp, was doomed to share the same fate. II. Astolphe, marquis de, grandson of Count Adam, born in Paris in 1793, died at his chateau of St. Gratien, near Pau, Sept. 1857, was the author of several novels, of which *Romuald* and *Le monde comme il est* (the former of a religious, and the latter of a philosophical tendency) have been translated into German. A tragedy of his, *Béatrix Cenci*, disappeared from the stage after a single representation. He travelled extensively on the continent, in England and Russia, and published 3 works of travels, of which that on Russia, *La Russie en* 1839, achieved the greatest popularity. It is written in a somewhat flippant, but entertaining, and in many respects instructive vein. It passed through many editions, and was translated into English and German.

CUSTIS, George Washington Parke, the adopted son of George Washington, born at Mount Airy, Md., in April, 1781, died at Arlington house, Fairfax co., Va., Oct. 10, 1857. He was the youngest child of John Parke Custis, a son of Mrs. Washington by her first husband, and an aide-de-camp to Gen. Washington at the siege of Yorktown. John Parke Custis died at Eltham, Md., of camp fever, just after the surrender of Cornwallis, leaving 4 children, the 2 youngest of whom were adopted by Washington. George Washington Parke Custis was brought up at Mount Vernon, subsequently pursued his classical studies at Princeton, and remained a member of Washington's family until the death of Mrs. Washington in 1802, when he went to reside at Arlington, an estate of 1,000

acres in the neighborhood of Washington, which he had inherited from his father. He erected the mansion known as Arlington house, and devoted his life to literary and agricultural pursuits. After 1852, when his sister Eleanor Parke Custis, who was married to Major Lawrence Lewis, died, he was the sole surviving member of Washington's family, and his residence was for many years an attractive resort on account of the many interesting relics of that family which it contained. Mr. Custis was the author of a number of remarkable orations, of several plays, and of the "Recollections of Washington," published at various times in the "National Intelligencer," of Washington. He was fond of painting, and in the latter part of his life executed a number of pictures of revolutionary battles. He was married in early life to Miss Mary Lee Fitzhugh, of Virginia, and left a daughter and several grandchildren.

CUTCH, or Cutch Bhooj, a native state of Hindostan, under the political superintendence of the Bombay government, bounded N. W. and N. by Sinde, E. by the Guicowar's dominions, S. by the peninsula of Cattywar and the gulf of Cutch, and S. W. by the Arabian sea. It lies between lat. 22° 47′ and 24° 40′ N., long. 68° 26′ and 71° 45′ E.; greatest length from E. to W. 205 m., breadth 110 m.; area, exclusive of the great salt marsh called the Runn of Cutch, which covers the N. part of the territory, and communicates with the gulf, 6,764 sq. m.; pop. 500,536. The Runn is 160 m. long from E. to W., from 4 to 80 m. wide, and about 7,000 sq. m. in area, including several islands. During the rainy season it is impassable except in a very few spots, and the S. part of the state becomes a vast island; but as the waters subside tolerable pastures appear here and there, and barren sand banks, covered with saline incrustations, are left exposed. The rest of the surface is hilly, and exhibits traces of volcanic action. Earthquakes are occasionally felt, and in 1819 a severe shock was experienced, which destroyed several hundred lives, and raised an enormous mound of sand and earth, several miles in extent, while a corresponding depression took place in the neighborhood. With the exception of a few fertile tracts, the country is generally sterile, and almost destitute of perennial rivers. The staple agricultural product is cotton, beside which there are plantations of sugar and of the common grains of India. Timber is scarce, but there are valuable minerals, including coal, iron, and alum. Cutch produces excellent horses, a poor breed of oxen, and numerous sheep and goats. Wild asses are met with in large herds near the Runn. The principal towns are Bhooj, the modern capital, and Anjar. The dominant race is a Rajpoot tribe, formerly noted for their almost universal practice of female infanticide.

CUTCH, Gulf of, an arm of the Arabian sea, running N. N. E. between Cutch and the peninsula of Cattywar (Guzerat), 110 m. long, and 25 m. wide at the entrance. It has often been described as very dangerous to navigation, but though full of eddies it is tolerably free from rocks, and is crossed by the natives at all seasons without fear.

CUTCH GUNDAVA, a province in the N. E. of Beloochistan, bordering on Sinde and Afghanistan, and bounded W. by the Hala mountains, in which is the famous Bolan pass. It lies between lat. 27° 40′ and 29° 50′ N., long. 67° 20′ and 69° 17′ E.; length from N. to S. about 160 m., breadth 130 m.; area, about 10,000 sq. m.; pop. about 100,000. It consists mainly of a vast arid plain, little cultivated, but in some parts thickly peopled. The S. E. part is occupied by the desert of Shikarpoor, 40 m. in extent, the soil of which is hardened clay, almost destitute of vegetation. The climate is proverbially sultry, water is scarce, and the chief productions are bajra and Indian millet. There are some fertile tracts, however, devoted to the cultivation of cotton, sugar, madder, and fruits. Capital, Gundava.

CUTHBERT, a saint and bishop of the English church, born near Melrose, probably in the first quarter of the 7th century, died March 20, 687, which day is observed as his festival. He was early attracted to the monastic life by the virtues of St. Aidan and his pious brethren, and was constrained by a timely vision to join himself to the fraternity. In 664 he was chosen prior of Melrose, and some years later was transferred to the charge of the monastery of Lindisfarne, or the "Holy island," a few miles S. of Berwick. His fondness for ascetic practices was not satisfied by the comparative ease and indulgence of this large establishment, and after a few years he retired to the lone and desolate isle of Farne, where he might enjoy a life of solitude. The island was barren, without wood or water; but the industry of the hermit, aided, according to the legend, by repeated miracles, opened springs, awakened fertility, and covered the ground with fields of grain. The fame of his holiness brought to him many visitors, among them Elfleda, daughter of the Northumbrian king Oswy, with whom he usually conversed through a window in the wall, not stirring out of his cell. For the purpose of more effectual isolation he dug a trench around his cabin. But he was compelled at last to yield to the persuasions of the Northumbrian king and church, and take the bishopric of the province of Lindisfarne. He held this office for 2 years, when, worn out by labors and austerities, he died in the island of Farne. His body, buried at his request in the monastery of Lindisfarne, was exhumed 11 years later, when, according to Bede, it was found to be undecayed. The Danish invasion, breaking up these northern convents, dispersed the monks over all the northern region. The bones of St. Cuthbert found a final resting place on the banks of the river Wear, and a convent, cathedral, and city were successively built around them. The legends and relics of St. Cuthbert remained for ages the chief treasure of the cathedral of Durham. He received the name of the "Thaumaturgus of

Britain." His memory was venerated for many centuries, and no intercession was deemed so powerful by the peasantry of the north of England. Pilgrimages were made to his shrine as to the shrine of St. Thomas of Canterbury. Diseases of the eye and palsy of the limbs were cured by the sight of his relics, or by kneeling at his tomb. A tooth of the saint was preserved in a nunnery in Paris, and a copy of John's Gospel in MS., taken from Cuthbert's coffin, was still extant in the last century. The Roman Catholic church celebrates on Sept. 4 the festival of the translation of St. Cuthbert's relics from Lindisfarne to Durham; in some parts of the region of Northumberland the day is still observed as a holiday.—St. Cuthbert of Durham is to be carefully distinguished from Cuthbert the Benedictine monk, who was a pupil of Bede, attended him in his last hours, and wrote a memoir of his life. Another Cuthbert was archbishop of Canterbury for 18 years from 740 to 758.

CUTLER, Manasseh, an American clergyman, born in Killingly, Conn., in 1744, died at Hamilton, Mass., July 28, 1823. He was graduated at Yale college in 1765, engaged in the whaling business, and opened a store at Edgartown, on Martha's Vineyard. While thus actively employed, he still continued his studies, and was admitted to the bar of Massachusetts in 1767, and pleaded a few cases in the court of common pleas. But this profession was not a congenial one; he cherished a preference for the ministry, and determined to prepare himself for it. After living in Edgartown 3 years, he removed with his family to Dedham, for the purpose of pursuing his theological studies with the Rev. Thomas Balch, whose daughter he had previously married. He was licensed to preach in 1770, and preached 6 months as a candidate at the Hamlet parish, then a part of Ipswich, Mass., but which was incorporated as a separate town under the name of Hamilton in 1793. Over this parish he was ordained, Sept. 11, 1771. At that period the difficulties between the colonies and Great Britain were assuming a threatening aspect, and he watched with deep interest the approach of the revolution. When the news of the battle of Lexington reached him, he made a short and stirring address to the minute men mustered in Ipswich on that occasion, and accompanied them on horseback to Cambridge, coming in sight of the enemy as they were retreating into Boston. Desirous of serving his country in deed as well as in word, he received a commission, Sept. 1776, as chaplain of the regiment commanded by Col. E. Francis, under whom and Col. Titcomb he served a year. Toward the close of the revolutionary struggle, as the physician of the Hamlet parish was employed in the army, and the people left destitute of medical advice, Mr. Cutler applied himself to the study and practice of medicine. For several years he administered to the bodily as well as spiritual maladies of his flock, for the former services receiving little or no compensation; yet notwithstanding these arduous labors, he soon became noted for his scientific taste and attainments. In 1781 he was elected a member of the American academy, and in the volume of memoirs published by that society in 1785 will be found scientific papers from his pen, bearing the following titles: "On the Transit of Mercury over the Sun, Nov. 12, 1782;" "On the Eclipse of the Moon, March 29, 1782, and of the Sun in the following April;" "Meteorological Observations, 1781, '82, '83;" "An Account of some of the Vegetable Productions naturally growing in this part of America;" and in the 3d volume of the memoirs appeared "Remarks on a Vegetable and Animal Insect." His botanical paper was the first attempt at a scientific description of the plants of New England. Dr. Cutler may well be termed the pioneer of botany in that region. He was induced to pursue this branch of science by casually meeting with an English work on botany, and his attention being thus drawn to the plants growing in his own immediate neighborhood, he examined and described 350 species according to the Linnæan system. In the preface he remarks that he may be guilty of many errors, as he had never before that year (1784) looked at plants with an eye to their scientific arrangement. During the same year he, with 6 others, ascended the White mountains; this party are said to have been the first white men who ever reached the summit. Dr. Cutler carried up instruments, and computed Mount Washington to be 10,000 feet above the level of the sea, thus giving it too great an elevation. With Dr. Peck's assistance he prepared the chapter on trees and plants in Dr. Belknap's "History of New Hampshire." Owing to the difficult and uncertain condition of affairs at the close of the revolutionary war, Dr. Cutler thought he could improve his condition by removing to the West, then a wild and almost unexplored part of the union. In 1786 a number of officers of the army met to form the Ohio company for the purpose of having their bounty lands located together. Major Winthrop Sargeant, one of the most efficient of their number, was acquainted with Dr. Cutler, and consulted with him about the proposed colony; the result was that he became a member of the company, and was appointed by its directors an agent in connection with Major Sargeant, with whom in this unexpected capacity Dr. Cutler visited the seat of government, and made a contract with the proper authorities for 1,000,000 acres of land north-west of the Ohio river. They also obtained a grant of 500,000 acres more, as an allowance for bad lands and incidental charges. By order of the directors Dr. Cutler, on his return home, immediately prepared to fit out an expedition for the intended settlement. He had a large wagon built and covered with black canvas, on which were painted in white letters the words: "Ohio, for Marietta on the Muskingum." The use to which this vehicle was appropriated, the circumstances under which it left New England and reached that then un-

cultivated wilderness, have placed this exploring wagon historically by the side of the Mayflower. Forty-five men were engaged to accompany it, and to help to settle and defend the new country for the space of 3 years. These emigrants started from Dr. Cutler's house, Dec. 1787; they were well armed, and fired a volley as a salute on their departure from his door. Their number having been increased to 60, they commenced the settlement of Marietta, April 7, 1788, under Gen. Rufus Putnam. In the further discharge of his agency Dr. Cutler started in a sulky for Ohio, which he reached in 29 days by a route of 750 miles. On Aug. 27, 1788, he performed the burial service for a child of Major Cushing, the first funeral that occurred among the whites at Marietta. While there he examined the fortifications and mounds in the neighborhood, which he considered were the work of a nation more civilized and powerful than any existing tribe of Indians. During the few weeks of his visit at the West, he was treated with great kindness, and highly honored; but he felt that at his age he had better remain in New England, and he bade a final adieu to the colony which he was in a great measure the means of founding. In 1795 President Washington tendered to him a commission as judge of the supreme court of the Ohio territory, which honor he declined. He was afterward elected by his people representative to the state legislature, and from 1800 to 1804 he served as a representative in congress.—Jervis, son of the preceding, one of the earliest emigrants to the western states, born in 1769 at Hamilton, Masss., died at Evansville, Ind., June 25, 1844. In 1788, at the age of 19, he joined the little company who, under Gen. Rufus Putnam, settled at Marietta, Ohio, then in the midst of Indian battle grounds. He was afterward able to say that he was the first man who ever cut down a tree for an emigrant's clearing in that great state. He was the last survivor of that pioneer company.

CUTLER, Timothy, D.D., president of Yale college, born in 1685, died in Boston, Mass., Aug. 17, 1765. He was graduated at Harvard college in 1701, and after a ministry of 10 years at Stratford, Conn., was chosen president of Yale college in 1719. In 1722 he renounced his connection with the Congregational churches, whereupon the trustees of the college passed a vote "excusing him from further service as rector of Yale college," and requiring in future from their rectors evidence of the "soundness of their faith in opposition to Arminian and prelatical corruptions." He then went to England, where he took orders. Returning to Boston in July, 1723, he became rector of Christ church, where he remained till his death. He published a sermon delivered before the general court at New Haven, in 1717, and one upon the death of Thomas Graves, 1757. A series of his letters published in Nichols's "Illustrations of Literary History," have considerable historical value.

CUTLERY (Fr. *coutellerie*), a general term including sharp cutting and many pointed instruments, made of iron and steel, as knives, forks, razors, &c. Instruments of this character were made in ancient times of various hard stones like flint; and shells also are still used by rude nations in the want of better cutting instruments. The ancient Egyptians appear to have possessed the art of giving a hardness to bronze, which adapted it to purposes for which only the best tempered steel is now found suitable. The Greeks also employed it before they were acquainted with the properties of steel; but these they appear to have understood in the time of Homer, distinct reference being made in the Odyssey to the process of tempering it. Their citations, as also those of the Romans, of districts famous for their production of iron, might still be correctly repeated; yet the ancient swords found in Herculaneum and Pompeii, the surgical and other cutting instruments, are not of the material, *ferrum*, always connected by the Latin writers with the weapons named, but of bronze. The manufacture of articles of cutlery was practised by the ancient Britons at as early a period certainly as the time of the Roman invasion, when they possessed broadswords, scythes, hooks, and spears, made from the products of their iron mines. Sheffield was a noted place for their manufacture in the time of Chaucer, who says of the miller of Trompington :

A Shefeld thwytel bare he in his hose.

Forks were not used till a much later period; even in the time of James I. they were regarded as a curious device of the Italians, worthy of a formal notice by the traveller Coryat. —Steel is the proper material for the cutting edges of all articles of cutlery; the backs may be made, if preferred for the sake of using a cheaper material, of iron, to which the steel is welded. So also of the handles of the instruments, or the tangs by which they are secured to handles of other materials. The steel for many instruments may be the blistered steel, or this after it has been fagoted and drawn down by tilt hammers to the bars called shear steel. This is a tough variety, easily worked, and answers very well for table knives, plane irons, scythes, &c. But when a fine finish is required, or great hardness, the blistered steel should be converted by fusion into cast steel, and the ingots be forged into bars, and these into the shapes required. Simple articles of cutlery, as chisels, are made by hammering a bit of cast steel into the shape of the cutting end, giving length enough to allow of considerable wear. This is made very thin, as it is intended only for the edge, and upon it is laid and welded a flat slip of iron, which has been forged into the shape of the chisel, and upon which the shoulder is shaped by driving it into a cavity in the anvil or a block with a suitably formed die to give the shape desired, and hammering upon the shank above a swage which fits around it like a collar. One side of the chisel is thus iron intended to be ground away:

the other side is the steel, which may be tempered to a proper degree of hardness. Small chisels are hammered entirely out of slender bars of steel.—The materials employed for scissors are still more various. Common qualities are of shear steel, with the blades only hardened. The best qualities are of cast steel, with blades, bows, and shanks all hardened. Large scissors, as the shears used by tailors, are of steel only in the blades, the rest being of iron; formerly only the edge was of steel. Some scissors are made of a good quality of cast iron, to which the English manufacturers give the name of run or virgin steel. Even of these there are inferior qualities, made for exportation, of common cast iron. A dozen pair of these sell for 3½*d*. But scissors of the best steel are manufactured with bows and shanks of gold that sell for more than 10 guineas the single pair. When made wholly of steel, the blade is hammered out at the end of a small bar, which is cut off with enough of the steel for the shank and bow. Through this a hole is punched, which is enlarged over the point of a small anvil or beak iron. By hammering and filing the exact shape is given; the joint is then squared, the hole bored for the rivet or screw, the blades are ground, and the bows smooth filed and burnished with oil and fine emery. Any ornamental devices are given by swaging in dies which contain the patterns. The blades are hardly measured except by the eye in the process of forging, and not being made with reference to pairing, the matches are afterward selected among many blades. Being sorted, and a pair screwed together, they are made to "walk and talk" well, as the "putter together" calls their playing with a smooth motion. After this follow various operations of hardening, grinding to give the exact shape, glazing and polishing, and the final burnishing with polished steel tools, which is done by women. An ingenious device is introduced, by which the cutting edges of the blades are brought in close contact with each other only at the point where the cutting is effected, which point moves from the end next the pivot to the extremity of the blades, in the operation of closing these. This consists in giving a slightly bowed shape to the blades, and raising upon the inner surface of each, close behind the pivot, a little triangular prominence, which makes the blades cant more and more toward each other as they are closed. The effect of these bulges and of the bow shape may be observed on holding a pair of scissors edgewise to the light; when closed the blades are seen to touch each other only at the point and at the centre on these enlargements, which are called the riding part. The arrangement also gives a certain degree of elasticity which adds to the smooth action of the instrument.—The blade of a table knife and of other large knives is hammered out upon an anvil at the end of a bar of shear or cast steel, and cut off. It is then welded on to a bar of wrought iron about ½ an inch square, and enough of this is cut off to form the bolster or shoulder and the tang. The blade is heated and hammered, or, as it is called, smithed, which serves to condense the metal and enables it to receive a higher finish. The mark of the maker is then stamped upon it, and it is hardened by heating to redness, and plunging into cold water. It is tempered to a blue color, and is then ready for grinding. The small blades of penknives are hammered entire out of the best cast steel. A temporary tang is drawn out to secure the blade in a small handle while it is ground. A number of blades are heated together for tempering, by being placed over the fire upon a flat plate of iron, their backs downward; when at the proper degree of redness so as to take a brown or purple color, they are dipped in water up to the shoulder. For razors the very best cast steel is selected, and when the blade is shaped upon the anvil from a bar as thick as the back of the razor and ½ an inch wide, it is well smithed to condense the metal as much as possible. Only the best steel will bear the working down of one part of the blade to the requisite thinness, while the back is left thick. By grinding on a dry coarse stone, the shape is further improved, and the scale is removed, which might interfere with the tempering. This operation is performed after the blade is drilled for the pin of the joint and stamped. It is next ground on a stone wet with water, and is afterward submitted to several processes of glazing and polishing, the last being effected on a soft buff wheel, covered with dry crocus and slowly revolving. Forks are hammered out of square steel rods, commonly of ⅝ inch. The tang and shank are roughly shaped at the end of the rod, and are then cut off with about an inch of the square steel beside. This is drawn out flat for the prongs; and the shank and tang are then shaped by the die and swage. The other end, heated to a white heat, is laid in a steel die upon an anvil, when another die attached to the under face of a heavy block of metal is allowed to fall upon it from the height of 7 or 8 feet. The prongs are thus shaped, and all but a thin film of steel removed from between them. This is afterward cleaned out with an instrument called a fly-press. A number of forks are then collected together and annealed by heating and allowing them to cool slowly. This renders them soft, so that they are easily shaped by the file and by bending. They are hardened by another heating to redness followed by sudden cooling in cold water, when they are at last tempered at the heat at which grease inflames.—The process of tempering, to which all articles of steel cutlery are subjected, is intended to remove the brittleness consequent upon the hardening of the steel. This is effected by reheating it to a proper temperature and suddenly plunging the metal into cold water. The higher the temperature of this reheating, the softer and stronger is the steel; at lower degrees of heat a greater hardness is secured, but with proportional brittleness. The different temperatures

with the corresponding colors appropriate for the tempering of various articles are given as follows by Mr. Stodart:

1. 430° F.; very pale straw yellow; temper suitable for lancets.
2. 450°; a shade of darker yellow; razors and surgical instruments.
3. 470°; darker straw yellow; penknives.
4. 490°; still darker straw yellow; chisels and shears for cutting iron.
5. 500°; brown yellow; axes and plane irons.
6. 520°; yellow, slightly tinged with purple; table knives and cloth shears.
7. 530°; light purple; } swords and watch springs.
8. 550°; dark purple; }
9. 570°; dark blue; small fine saws.
10. 590°; paler blue; } large saws with teeth to be set with pliers and sharpened with a file.
11. 610°; still paler blue; }
12. 630°; same, with tinge of green; too soft for steel instruments.

The film which presents the color appears to be owing to the oxygen of the air, as it could not be produced by Sir Humphry Davy in nitrogen. The action is probably upon the carbon of the steel, and the effect is to partially protect the steel from oxidation producing rust.—In places where the manufacture of cutlery is carried on upon an extensive scale, as at Sheffield, the grinding and polishing is conducted in large mills or "wheels" devoted to this purpose. The rooms of these establishments, called hulls, are furnished each with 6 arrangements for grinding, which are called troughs. They consist of the stone for grinding, a polisher, and the pulley for driving them. The stones are of various sizes, from 4 inches to 2 feet in diameter, adapted to the articles to be ground. The convex surface of the small 4 or 5 inch stones gives the concavity on the face of the razor blades. Some are used dry, and others, employed for grinding articles, the temper of which might be injured by the heat, are kept wet. The dry grinding is more expeditious, but unless the troughs are furnished with a ventilating fan and flue for carrying off the fine metallic particles and the dust from the stones, the health of the workmen is very seriously affected. Fork grinding, which is always done without water, is described by Dr. Holland of Sheffield as probably more destructive to human life than any other pursuit. The air of the rooms becomes filled with the fine dust, and the inhaling of this produces cough and inflammation of the lungs, reducing the average age of the fork grinders to 30 years or less. Glazing or lapping succeeds to the grinding. Each process consists in applying the articles to the face of a revolving wheel, upon which a lump of emery cake is occasionally rubbed. The glazier is a wheel made of 6 or 8 pieces of some close-grained wood, arranged so that the grain lies as much as possible in the line from the centre to the circumference. The lap is a thin wooden wheel faced around its edge with a rim or tire of metal. This usually consists of 4 or 5 parts of lead to 1 of tin, and is secured by being run when melted between the projecting edges of the face of the wheel. After being cast it is turned true, and is then indented or grooved in order to make it hold the dressing of emery and oil. Various qualities of polish are produced upon steel blades by drawing them from end to end across the revolving lap, according to the fineness of the emery with which this is fed, or the smoother face given by the application of a stick of charcoal succeeded by that of a smooth piece of flint. For giving the finest polish to razors and other articles of fine cutlery, polishing wheels of wood are used with faces covered with leather and charged with dry crocus.—The handles of articles of cutlery are made from a variety of materials; as the ivory of the elephant and walrus, different kinds of horn, mother-of-pearl, tortoise shell, and some sorts of wood, as cocoa and snakewood. Ivory is used more than other materials for table knives, &c. A solid piece of the right size is cut out, and the hole for the tang is bored in one end. Sometimes this is made entirely through the handle, so that the end of the tang may be secured by riveting upon a metallic cap which is thus attached to the extremity of the handle. When it passes only part way through, it is secured by cement, or by a late contrivance of the Messrs. Rodgers of Sheffield—a little spring catch fastened to the tang, which falls into a notch made in the cavity in the handle as the tang is introduced, and prevents its being withdrawn. Balance handles are made with lead introduced into the further end of the cavity for the tang, the object being to counterbalance the blade, so that the knife when laid down rests only upon the outer extremity of the handle and the projecting shoulder of the blade at its other end. Common knives are made with a thin flat tang, to which strips of wood or bone are securely riveted for a handle, one on each side. The handles of penknives are much more elaborate in their construction, involving a greater variety of processes than the blades themselves. The springs are nice pieces of work requiring their peculiar temper, and a final glazing upon their backs. The slips for the handles demand great care in their fitting and frequently in their ornamentation. The thin plates, called scales, which form the sides and divisions of the handle, must be exactly adjusted to all the other parts, to which they are secured by rivets passing through the springs and outer pieces. It is stated that a three-bladed knife passes through the finisher's hands about 100 times.—The manufacture of table cutlery is of recent introduction in the United States. It was commenced in January, 1834, by Mr. John Russell of Greenfield, Mass., and some time afterward was undertaken by the Messrs. Ropes of Portland, Me., and the Messrs. Lamson of Shelburne Falls, Mass. It made but slow progress until the processes were improved by the application of machinery to form the blades, by the plan of Mr. Russell, which has since been introduced in the European works. The establishment of the Green river manufacturing company, near Greenfield village, has produced for several

years past table cutlery and butcher and shoe knives to the amount of $300,000 annually, giving employment to from 300 to 340 men and boys, and consuming every year 100 tons of cast steel, 180 tons of Granadilla wood for handles, 50 tons of ebony, 50 tons of horns of cattle, 16,500 lbs. of ivory, 150 tons of anthracite, 15,000 bushels of charcoal, 175 tons of grindstones. Their knives are found in all parts of the United States, and are exported to South America, and some even to Australia and other parts of the world. The aggregate value of cutlery produced in Massachusetts in 1855 was $573,625, chiefly in Franklin county. As regards the quality of the articles, Fleischmann, in his work on the branches of industry in the United States, remarks that "the manufacturers of cutlery have far surpassed those of the old world in the manufacture of tools, and that not merely in the excellence of the metal used, but especially in the practical utility of their patterns, and in the remarkable degree of finish of their work." This finish, it may be remarked, appears to be applied in American work only where it will be conspicuous, and hence useful; but in the machinery of American clocks and watches it is saved as a useless expense, adding as it does in English work of this class much to the cost, with no corresponding benefit. The value of cutlery exported from the United States during the year ending Sept. 30, 1857, was $12,663, and of imports, $2,140,824, viz.: from England, $1,953,396; Germany, $87,540; France, $73,315; other countries, $26,573. During the 11 months ending Nov. 30, 1858, the imports of cutlery and hardware from England amounted to about $2,800,000.

CUTTACK, a province of British India, in the Bengal presidency, bounded E. and S. E. by the bay of Bengal, and lying between lat. 19° 40′ and 21° 45′ N., long. 85° 8′ and 87° 31′ E.; area 6,705 sq. m.; pop. 1,556,395. It is divided into the districts of Pooree, Cuttack proper, and Balasore. The district of Cuttack has an area of 3,061 sq. m. It is well watered and has a diversified surface, the coast being level and the N. W. part traversed by wooded hills which produce teak and other valuable timber. Wheat, maize, rice, sugar, pulse, spices, and dyestuffs are the principal productions. The best salt in India is made on the coast, and iron is found among the hills. The climate is hot and unhealthy. The province was acquired by the British from the rajah of Berar in 1803. In 1817 it was the theatre of a serious revolt, and in 1857 was somewhat disturbed, though free from any considerable outbreak. The Cuttack Mehals, a group of 18 petty states, with an aggregate area of 16,929 sq. m., and a pop. of 761,805, became subject to the East India company on the acquisition of the province. They comprise a small proportion of arable land, but are valuable for their timber.—Cuttack, the capital of the above district, is situated on a tongue of land between 2 branches of the Mahanuddy river, 60 m. from its mouth and 220 m. S. W. from Calcutta; pop. estimated at 40,000. Embankments faced with stone protect it from the frequent overflows of the river, which has been known to rise 6 feet above the level of the town in a single night. It is half in ruins, has little trade, and contains no handsome buildings. Many of its private dwellings, however, are well built of brick or stone, and it has manufactories of cooking utensils and shoes. Near it is the decayed fortress of Barahbattee, now used as a quarry. The town was the capital of the ancient province of Orissa, and its name, from the Sanscrit *catak*, signifies a royal residence. It was captured by the British in 1803.

CUTTER, a small vessel with one mast, and a straight running bowsprit, which may be run in upon deck. It differs from the sloop by having no stay to support its jib. They are fast-sailing, and are often employed by smugglers, and also by the government for the purpose of apprehending them; in the latter case they are termed revenue cutters.

CUTTLE FISH (*sepia officinalis*), a molluscous animal or shellfish, a species of the family *sepiadæ*, of the class of cephalopods. The shell of the animal, which characterizes the family, is a broad laminated plate imbedded in the back part of the mantle, and terminating behind in an imperfectly chambered apex (*mucro*), which is supposed to answer as a sort of guard or fender in the collisions the animals are exposed to in swimming backward. This shell is a friable calcareous substance known as cuttle bone, or pounce, and used for polishing soft metals. The bone of a Chinese cuttle fish has been found 1½ feet in length. As a fossil the bone has been met with in the eocene clays of the London basin, and of forms indicating different species from those now living. The cuttle fishes are provided with 8 arms and 2 long tentacles, all of which radiate from around the head. The tentacles are provided with suckers, and reach beyond the arms to seize prey, and serve also to moor the animal. The suckers hold so fast to objects that the limb will part from the body before they let go. By means of their arms they walk on the bottom with their heads downward; the same organs aid them in swimming, and a propelling force is moreover obtained by violently ejecting water from their branchial chamber. As a means of defence they are provided with an ink bag, the discharge of which opens into the funnel by which the water is ejected from the 2 gills; when attacked the animal instantly darkens the water with the black fluid from this bag, and retreats in the obscurity it occasions. Several species of sepia produce this inky substance. It was well known to the ancients, and is described by Aristotle. It appears to have been used for writing; and in modern times it has served for the preparation of the brown pigment called sepia, but this is now prepared from lampblack. The ink consists of carbon in a finely divided state, of albumen, gelatine, and phosphate of lime. The bag must be dried immediately when taken from

the animal, as it is liable to putrefy. The dried material is triturated with a caustic alkali, and then boiled with a solution of the same. After filtering, the alkali is neutralized by adding an acid, and the precipitated sepia is collected, washed, and dried. Buckland states that he had some sepia prepared from ink bags of extinct cephalopods found preserved in a fossil state in the lias formation, and that the pigment was of such excellent quality as to attract the attention of a celebrated painter. Cuttle fishes are found in the open sea in almost all parts of the world; and they appear near the coasts periodically in shoals. They have large eyes placed on the sides of the head, which seem designed for use in the night or in the darkness of deep waters, as the animal avoids the light of day. No other mollusca attain so large size as the cuttle fish. One has been met with of about 6 feet in length.

CUTTY STOOL, the stool of repentance, formerly employed in the Scotch kirk, for offenders against the law of chastity. The criminal having been deprived of church ordinances, and duly taken to task privately for his or her offence, was required to make a public acknowledgment of the sin prior to being restored to communion. The penance consisted in occupying the cutty stool, in face of the congregation, and being lectured by the minister on the enormity of the offence. Sometimes the offender was clad in a white sheet, the stool of repentance being painted black, and placed conspicuously in an upper gallery. The custom has fallen into disuse.

CUT-WORM, the caterpillar of an owlet moth of the tribe of *noctuæ*, and group *agrotididæ;* this name has also been given to many other grubs and worms living in the ground. This caterpillar remains by day about the roots of plants, and comes forth at night to cut off the tender stems and leaves of cabbages, beans, corn, and many other culinary plants. Some of the moths of this family fly by day, others only at night; the wings are nearly horizontal when closed; the thorax smooth and slightly convex; the antennæ of the males generally with 2 rows of fine tooth-like points on the under side; the fore legs are often quite spiny. Most of these moths appear in July and August, laying their eggs in the ground; in Europe the caterpillars are hatched in early autumn, and feed on the tender roots of plants; descending deeper in winter, they remain torpid until spring. The caterpillars of the agrotidians are smooth, shining, naked, dark-colored, with longitudinal pale and dark stripes, and a few black dots on each ring; cylindrical, short, and thick, with 16 legs; the chrysalis is transformed in the ground, without a cocoon. The most destructive European species are the winter dart moth (*agrotis segetum*), and the wheat dart moth (*A. tritici*), both destroying the roots and leaves of winter wheat and buckwheat; the eagle moth (*A. aquilina*), an occasional pest in vineyards; and the antler moth (*charæas graminis*), very destructive in meadows and mountain pastures. The American species have the same habits, appearing about the same time, destroying whole fields of corn, potatoes, cabbages, beans, and other vegetables, and also asters, pinks, balsams, and other ornamental plants. The caterpillars vary in length from 1 to 2 inches, and are thick, of a dark ashy gray color, with a brown head, and a pale dorsal stripe, with minute black dots; the chrysalis is of a shining dark brown, and the moth appears from the 20th of July to the middle of August. There are at least 5 species in New England. The largest is the *A. telifera* (Harris), having the fore wings light brown, divided by 2 transverse bands of wavy dark brown lines, and with 3 spots (one lance-marked) encircled with dark brown; the hind wings are pearly white, the abdomen gray; expanse of wings at least 2 inches. The *A. inermis* (Harris) is slightly smaller, resembling the preceding except in the absence of the lance-shaped spot; the thorax is reddish brown. The *A. messoria* (Harris) has the fore wings reddish gray, with 5 wavy blackish bands and 3 wing spots; the hind wings whitish, and dusky brown behind; the body grayish; the expanse of wings $1\frac{3}{4}$ inches. The *A. tessellata* (Harris) expands only $1\frac{1}{4}$ inches; the fore wings are dark ash, with only a faint trace of bands, and with large alternate pale and black spots; the hind wings brownish gray in the middle, and blackish behind. The *A. devastator* (Harris), the moth of the cabbage cut-worm, has the fore wings dark satiny ashy gray, with 4 narrow, wavy, whitish bands edged with black, and white dots and dark spots; the hind wings are a light brownish gray, dusky behind; body gray; expanse of wings $1\frac{1}{2}$ to $1\frac{3}{4}$ inches. All these fly only at night; the last is not easily taken from its rapid motions, and often flies into lamps and candles after the middle of July. Other species are described by Dr. Harris. The ravages of the true cut-worms are not prevented by any treatment of the seed, as they feed only on the young sprouts and stalks; the only effectual way to prevent their depredations is to open the earth daily at the foot of the growing plants and kill the worms, which are easily found. It is said that a manure of sea mud will protect a garden from these worms; some cultivators protect their cabbage plants by wrapping a walnut leaf or paper cone firmly around the root, secured by an earth embankment. Turning up in the fall lands which are to be planted the next year, exposes many grubs to cold and to the birds, but has been considered a remedy of doubtful utility.

CUVIER, Georges Chrétien Léopold Dagobert, a French naturalist, born at Montbéliard (now a French town, but formerly the chief place of a principality belonging to the duke of Würtemberg), Aug. 23, 1769, died in Paris, May 13, 1832. The family came originally from a village in the Jura which still bears the name of Cuvier; at the time of the reformation it settled at Montbéliard, where some of its members held offices of distinction. The grandfather of

Cuvier had 2 sons, the younger of whom entered a Swiss regiment in the service of France; a brave man and an excellent officer, he rose to high honors, and at the age of 50 married a lady considerably younger than himself; by her he had 3 sons; the oldest died in infancy, the second was the subject of the present sketch, and the third was Frédéric Cuvier. Of delicate constitution, his mother watched over him with the tenderest care, and took upon herself the management of his early education; she taught him to read, made him repeat to her his Latin lessons, instructed him in drawing, and, by causing him to read the best works in history and literature, developed in his youthful mind that ardent desire for knowledge which was so remarkable in him. At the age of 10 he entered the gymnasium, or high school, where he remained 4 years, distinguishing himself in every branch there taught; at this early period his taste for natural history was stimulated by reading a copy of Buffon which he found at the house of a relative; his memory was so retentive that at the age of 12 he was perfectly familiar with birds and quadrupeds. At the age of 14 he formed a kind of academy from among his schoolmates, of which he was president, at whose weekly meetings the merits of some book were discussed; here his declamatory and administrative powers began to manifest themselves. A petty trick of a malicious teacher prevented his being sent to the free school of Tübingen, where he would have prepared himself for the church; and this change in his studies he always regarded in after life as a most fortunate accident. Charles, duke of Würtemberg, took him under his special favor, and sent him at the age of 14 to the academy of Stuttgart, in March, 1784; after studying philosophy one year, he applied himself to the science of fiscal administration, because it gave him an opportunity to pursue his favorite natural history in books, in the fields, and in cabinets. While here one of the professors gave him a copy of the "System of Nature" by Linnæus, which was his library on natural history for several years. Occupied by such reading and the collection of specimens, he did not neglect his class studies, but obtained several prizes for his eminent proficiency. He would doubtless soon have been appointed a professor, but the circumstances of his parents did not permit delay; a situation as private tutor in Normandy being offered him just as he left Stuttgart, he accepted it, and entered upon its duties in July, 1788, at the age of 19 years. While in the family of the count d'Héricy, he followed natural history with great zeal, and was very favorably situated for the study of both terrestrial and marine animals; he remained here until 1794. Some *terebratulæ* having been dug up in his vicinity, he conceived the idea of comparing fossils with living species; and the dissection of some mollusks suggested to him the necessity of a reform in the classifications of animals; here originated the germs of his two great works, the *Ossemens fossiles*, and the *Règne animale*. Through his acquaintance with M. Tessier, who had fled to Normandy during the reign of terror, Cuvier began a correspondence with Geoffroy St. Hilaire, Lacépède, and other Parisian savants, on subjects of natural history; in the spring of 1795 he accepted their invitation to come to Paris, and was appointed professor in the central school of the Pantheon, for which he is said to have composed his *Tableau élémentaire de l'histoire naturelle des animaux*, in which he first gave to the world his ideas on zoological arrangement. M. Mertrud had been appointed professor of comparative anatomy at the *jardin des plantes;* at his advanced age, feeling himself unable to discharge all its duties, he called upon Cuvier to assist him, who at this time invited his brother Frédéric to join him. From this moment he commenced the collection of comparative anatomy, which has since become so famous and extensive. In 1796 the national institute was formed, and Cuvier was associated with Lacépède and Daubenton in the section of zoology, and was its third secretary. In 1799 the death of Daubenton made vacant for Cuvier the chair of natural history at the college of France; and in 1802 he succeeded Mertrud as professor of comparative anatomy at the *jardin des plantes*. In 1800, M. Duméril, one of Cuvier's pupils, published the 1st and 2d volumes of his lectures, under the title *Leçons d'anatomie comparée;* the 3d, 4th, and 5th of the 1st edition, prepared by G. L. Duvernoy, appeared in 1805. In 1802, appointed by Bonaparte one of the inspectors-general to establish *lycées* or public schools in France, he founded those of Marseilles, Nice, and Bordeaux. He quitted this office in 1803 on being elected perpetual secretary to the class of natural sciences in the institute, a position which he held to the day of his death; in this capacity he made in 1808 his celebrated report on the progress of the natural sciences since 1789, so pleasing to the emperor, which appeared in 1810. In 1808 he was also made one of the counsellors for life to the imperial university, by which he was frequently brought into close communication with Napoleon. In 1809–'10 he was commissioned with the organization of the new academies in the Italian states which were annexed to the empire. In 1811 he was sent on a similar mission to Holland and the Hanseatic towns, and was made chevalier of the legion of honor. In 1813, though a Protestant, he was sent to Rome to organize a university there, and was also appointed master of requests in the council of state. In the same year he was made imperial commissioner to go to the left bank of the Rhine, and endeavor to arouse the people against the troops then marching to invade France; stopped at Nancy by the approach of the allied armies, he was obliged to return. In 1814 he was named councillor of state by Napoleon, which honor was continued to him by Louis XVIII., as also that of royal commissary, which enabled him to

introduce many improvements in criminal and civil law; he was also made chancellor to the university, which office he retained during life, notwithstanding the prejudices and resistance which as a Protestant he was constantly obliged to encounter. In 1818 he visited England with his family for the purpose of observing its political and scientific institutions; while there he was elected a member of the French academy. In 1819 he was made grand master to the university, and president of the *comité de l'intérieur;* in this year Louis XVIII. created him baron, as a mark of personal esteem. In 1822 he was appointed grand master of the faculties of Protestant theology, which gave him the superintendence of the religious, civil, and political rights of his creed; and in 1827 was added to this the management of the religious affairs of all the creeds in France except the Roman Catholic. In 1824 he acted as one of the presidents of the council of state at the coronation of Charles X.; and in 1826 was made grand officer of the legion of honor by that king. In 1827 he was offered the appointment of censor of the press, which he instantly refused. In 1830 he recommenced his lectures at the college of France, on the "History and Progress of Science in all Ages," which were continued until his death; in this year he made a second visit to England, where he happened to be when the revolution took place which placed Louis Philippe on the throne of France. He continued to enjoy all his honors, dignities, and important offices under the citizen king; in 1832 he was created peer of France, and the appointment of president to the entire council of state only wanted the king's signature, when Cuvier expired. Cuvier lost his mother in 1793, and his father in 1795. In 1803 he married Madame du Vaucel, a widow with 4 children, 3 sons and a daughter, the latter of whom devoted herself to him in his last illness; by this marriage he had 4 children, of whom 3 died in early childhood; his only remaining child, Clémentine, died in 1828, at the age of 22, on the eve of marriage; his wife and two of her first children survived him. On May 8, 1832, he opened his course of lectures at the college of France; at the close of the first lecture he spoke these words, which seemed to indicate a presentiment of his approaching end: "Such, gentlemen, will be the objects of our investigation, if time, my own strength, and the state of my health, permit me to continue and finish them." After this lecture he felt slight pain and numbness in the right arm, and his throat became affected; on the 3d day both arms were seized, and the power of swallowing was lost, all his mental faculties and the power of speech remaining unaffected; conscious of his approaching death, he was perfectly calm and resigned. Four hours before he died he was carried, at his own request, into the memorable cabinet where the happiest and proudest hours of his life had been spent, and where he wished to draw his last breath. Baron Pasquier says: "His countenance was in a state of perfect repose, and never did his noble head appear to be more beautiful, or worthy of admiration." The paralysis of the voluntary muscles spread rapidly, fever set in, the lungs became unable to perform their functions, and he gradually sank away without a struggle. Feeble in his youth, by the time he arrived in Paris his health was seriously deranged, and his symptoms were those of incipient consumption; but the excitement of new studies, the change in his habits, and the exertion of lecturing, worked such an alteration in him that he enjoyed good health until his final illness. He was below the middle stature, with very fair skin, and reddish hair up to the age of 30; as his health improved, his hair became darker; at 45 he grew stout, but was always well; at 60 he scarcely seemed more than 50; according to Duvernoy, he never used spectacles when reading or writing. The size of Cuvier's brain was remarkably large, weighing nearly a pound more than the average brain of man; and the excess of weight depended almost entirely on the great development of the cerebral hemispheres, the seat of the intellectual faculties.—A history of the labors of Cuvier in the domain of natural history would be nothing less than the history of natural science in the first half of the 19th century. Linnæus in 1735 published his *Systema Naturæ*, a mere sketch of the animal kingdom, but still a simple and valuable classification; he did not always select the best characters for the foundation of his divisions, but he accomplished a great deal, and by his generic and specific names contributed much to a knowledge of animals and their affinities. When Cuvier brought his great mind to the work, and formed a system based on the invariable characters of anatomical structure instead of external resemblances, he discovered the true basis of a natural classification of the animal kingdom. The system of Cuvier, which is now generally adopted in its main features, is already given in the article Animal. Various modifications have been adopted, and numerous errors have been corrected since its publication, more especially by Prof. Agassiz, upon whom the mantle of Cuvier seems to have fallen. Cuvier first introduced into zoology the fourfold division, founded on different plans of structure, of *radiata*, *mollusca*, *articulata*, and *vertebrata;* and this has been the basis of all modern improvements in the science. The first improvement on Cuvier's system was the removal of the helminths from the radiata, and placing them among articulata; then the infusoria were removed from radiata, and divided among plants, mollusca, and articulata; the only important change in mollusca is the removal of the cirripeds from them and placing them under articulata; in articulata, the arachnida have since been united with the insects proper; these 3 branches include all invertebrates. The division of vertebrates into fishes, reptiles, birds, and mammals, has been modified by making amphibia a class between fishes and

reptiles; by separating the selachians, ganoids, and myzonts from fishes proper; and by reducing the number of orders among birds from 6 to 4, and among mammals from 9 to 3. The classification of Prof. Agassiz, founded on that of Cuvier, and published in the first volume of his "Natural History of the United States," is here given as the best at present known, though its author does not consider it as by any means a perfect one; his present investigations will doubtless modify it considerably, especially in the orders, and in the class of fishes:

Branch I. Radiata.

Class 1. *Polypi:* including the 2 orders, actinoids and halcyonoids.
" 2. *Acalephæ:* 3 orders—hydroids (including siphonophoræ), discophoræ, and ctenophoræ.
" 3. *Echinoderms:* 4 orders—crinoids, asteroids, echinoids, and holothurioids.

Branch II. Mollusca.

Class 1. *Acephala:* 4 orders—bryozoa (including the vorticellæ), brachiopods, tunicata, and lamellibranchiata.
" 2. *Gasteropoda:* 3 orders—pteropoda, heteropoda, and gasteropoda proper.
" 3. *Cephalopoda:* 2 orders—tetrabranchiata and dibranchiata.

Branch III. Articulata.

Class 1. *Worms:* 3 orders—trematods (including cestods, planariæ, and leeches), nematoids (including acanthocephala and gordiacei), and annelides.
" 2. *Crustacea:* 4 orders—rotifera, entromostraca (including cirripeds), tetradecapods, and decapods.
" 3. *Insects:* 3 orders—myriapods, arachnids, and insects proper.

Branch IV. Vertebrata.

Class 1. *Myzontes:* 2 orders—myxinoids and cyclostomes.
" 2. *Fishes proper:* 2 orders—ctenoids (as the perch) and cycloids (as the cod). [This division will probably be considerably modified by its author.]
" 3. *Ganoids:* 3 orders—cælacanths, acipenseroids, and sauroids; and doubtful, the siluroids, plectognathi, and lophobranches.
" 4. *Selachians:* 3 orders—chimæræ, galeodes, and batides.
" 5. *Amphibians:* 3 orders—cæciliæ, ichthyodi, and anura.
" 6. *Reptiles:* 4 orders—serpents, saurii, rhizodontes, and testudinata.
" 7. *Birds:* 4 orders—natatores, grallæ, rasores, and insessores (including scansores and accipitres).
" 8. *Mammalia:* 3 orders—marsupialia, herbivora, and carnivora.

The general order in the classes and in the orders is from lowest to highest. By a glance at this classification, the reader will perceive to what extent it is founded on that of Cuvier; the system of 1812 differs from that of 1857 mainly in the points derived from embryological development in the latter. The grand idea of Cuvier, and his followers since, was to discover the plan of created beings by the study and comparison of the intimate structure of their organism—to establish the true philosophy of natural history on the laws of organization. With him comparative anatomy and zoology went hand in hand, assisting each other continually; and from their united facts he deduced the laws of a new science, that of fossil animal life, astonishing the world with the magnitude of his conceptions and the grandeur of his discoveries. Linnæus had confounded in his class of worms all animals which have not red blood, including more than half of the animal kingdom. Cuvier's first researches were on this class of animals, which he in 1795 divided into the classes of his invertebrate series. His very first observations in 1792 were on the anatomy of the common patella, certain dipterous insects, and crustaceans, in the 2d volume of the *Journal d'histoire naturelle.* Since the time of Aristotle, the invertebrata had always been neglected until Cuvier published his divisions in 1795, from which may be dated the reformation of natural history. Beside the memoir above mentioned, in the same year he took up the mollusca, studied their structure, divided them into orders, and commenced a series of observations which led to the publication of his memoir on the history and anatomy of mollusks, published in 1817.—Comparative anatomy was the basis of Cuvier's zoology, and we find mémoirs on this subject from 1795 to 1831; the *Leçons d'anatomie comparée*, already alluded to, was but the preface, as it were, to a more extended work, whose plan he had nearly completed when death overtook him; such as it is, a monument of vast labor, it has furnished materials for the development of this science by other hands, and has from its own stores enabled critics to point out unavoidable deficiencies; from a heap of dry, unconnected facts concerning the structure of animals, he obtained the general laws of organization, the limit of variation in each organ, the marked influence of some upon the general system, the subordination of many, and the coexistence or incompatibility of others. Among the prominent points are: the development of the teeth; the structure of the larynx of birds, of the nasal fossæ and organs of hearing in cetaceans, and of the respiratory organs in the perenni-branchiate amphibia; the comparison of the brain in the vertebrata, and the relation of its development to the intelligence; the respiration, animal heat, muscular force, sensory and digestive systems of these animals. For this treatise on comparative anatomy he received one of the decennial prizes instituted by Napoleon in 1810. Cuvier in his scientific labors stated positively only that which he knew from personal observation, and therefore early directed his attention to collecting objects of natural history; the great collection of comparative anatomy at the *jardin des plantes*, made chiefly through his own exertions, contributed the materials of which he made such a remarkable use; this collection was also necessary for the determination of fossil species, which he began to investigate while residing in Normandy. In 1796 appeared his memoir on the skeletons of the *megalonyx* and *megatherium*, and on the skulls of fossil bears from the caverns of Gaylenreuth; from this period until 1812 he contributed many papers on fossil bones, the most important of which were printed in the *Annales du muséum d'histoire naturelle*, and were afterward published under the title of *Recherches sur les ossemens fossiles;* the 1st edition, in 4 volumes 4to., appeared in 1812, a 2d in 1817, and a 3d in 1825, with a preliminary discourse on the "Revolutions of the

Surface of the Globe." Deposits of mollusks and other marine animals had long been known to exist at great distances from and heights above the sea, confirming the popular traditions of most nations regarding deluges of greater or less extent. Large bones, discovered in caverns or dug from the earth, had given rise to traditions, equally wide-spread and ancient, of the existence of giants in the early ages of the world; even philosophers regarded the fossil impressions in the rocks and the shells in the ground as accidental freaks of nature. It was reserved for Bernard Palissy, an unlettered potter, to discover the animal origin and former existence of the objects alluded to above; though he defied the learned men of the 16th century to disprove his statements, it was not until the end of the 17th that his ideas met with a scientific appreciation. Founded on these now acknowledged facts, many theories, all more or less fanciful, were successively adopted and abandoned until the middle of the 18th century, when more rational views began to prevail, and the study of fossils to excite that attention which, in the hands of Cuvier, resulted in establishing many of the positive laws of geology and palæontology. The bones of the giant Teutobochus had been long since recognized as those of elephants; the skeleton of the supposed *homme témoin du déluge* became, under the penetrating eye of Cuvier, that of a gigantic aquatic salamander. Daubenton first demolished the race of giants; Pallas showed the existence of the elephant, rhinoceros, and other tropical animals, in Asiatic Russia in former geological epochs, and an elephant of extinct species was found with its flesh preserved on the borders of the Arctic ocean. From such facts Buffon conceived the idea that the polar regions had gradually become colder, and that their animals had by degrees emigrated southward; this was rendered improbable by the condition of the animal remains, and the theory of a sudden refrigeration was substituted. The fact of ancient creations of animals, entirely distinct from the present species, and long since exterminated, was set at rest by the comparison of living and fossil animals by Cuvier; in his first memoir on fossil elephants in 1800 he announced his views on extinct animals, the commencement of a series of observations unparalleled in the annals of science for brilliancy, profound insight into natural laws, and importance of their results to succeeding ages. His knowledge of comparative anatomy was such, that a bone, or even a portion of one, was sufficient for the restoration of a fossil animal which he had never seen, simply from the principle of the unchangeable relations of organs. He made 3 epochs of creation: the 1st comprised the mollusks, fishes, and monstrous reptiles; the 2d, the *anaplotherium, palæotherium*, the singular pachyderms of the neighborhood of Paris; the 3d, the mammoth, mastodon, gigantic sloths, &c.; after all these came a 4th, the age of man and the present creation. Anterior to the 1st epoch was a period in which no organic life, either animal or vegetable, existed on the earth. To Cuvier was principally due the discovery and exploration of this *terra incognita* of remote ages. In 1817 was published the first edition of the *Règne animal* (4 vols.), which has served as the basis for subsequent zoological classifications.—The last great work of Cuvier, which he undertook in conjunction with Valenciennes, is the *Histoire naturelle des poissons;* this contains the application of his principles of classification to the class of fishes; 8 volumes of this work were published at the time of his death, the 1st having appeared in 1828, and the 8th in 1831; Valenciennes was intrusted with the task of completing it in 20 volumes, but several more than this number have been published. Linnæus had determined about 500 species, and Lacépède 1,500; the title of Cuvier's work implies the magnitude and successful prosecution of his own labors, viz.: "Natural History of Fishes, containing more than 5,000 Species of these Animals, described after Nature, and distributed according to their Affinities, with Observations on their Anatomy, and Critical Researches on their Nomenclature, ancient as well as modern." His orders of the bony fishes were founded chiefly on the structure of the fins, whether spiny or soft, and on their position on the lower surface; the cartilaginous fishes were divided into those with free and those with fixed gills. The minuteness of detail, the clearness of description, and the discrimination of his criticisms on the works of others, are eminently instructive; and the rapid advance of ichthyology is sufficient proof of the excellence of his method and the faithful performance of his task. Since his time the classification of Agassiz founded on the structure of the scales, and that of J. Müller based on internal anatomy, have exerted their influence on this science. The great defect in all these systems is that they place too great and almost exclusive stress on single characters; it is to be hoped that, from the combined excellences of these systems, and from the results of embryological researches now so extensively pursued both in Europe and the United States, a natural classification of fishes, the expression of their plan of creation, will soon be evolved.—Beside the "Report on the Progress of the Physical Sciences," undertaken at the request of Napoleon, Cuvier displayed the almost universality of his acquirements by his lucid reports before the institute on these sciences, embracing the large and varied subjects of meteorology and natural philosophy in general, chemistry and physics, mineralogy and geology, botany, anatomy and physiology, zoology, travels connected with natural science, medicine and surgery, the veterinary art, and agriculture. He contributed many articles on natural history to the *Dictionnaire des sciences naturelles;* prominent among these is the one on "Nature," in which he combats the meta-

physical systems of pantheism and the physio-philosophers, and refers every thing to the wisdom and goodness of an almighty Creator. He wrote many articles for a kindred work, the *Dictionnaire des sciences médicales*, the most important of which is that on "Animal;" in this, after tracing "animality" from the lowest to the highest, he concludes with a comparison between plants and animals. As secretary of the academy of sciences, it was his duty to read historical notices of deceased members at its public meetings; 3 volumes of these sketches by Cuvier have been published, containing 39 different articles. Beside these, he delivered several discourses at funerals of academicians, and reports to the academy. One of his discourses deserves special mention, that before the academy on the distribution of the Monthyon prizes for virtuous actions, in 1829; on this occasion a prize of 5,000 francs ($1,000) was awarded to Louise Scheppler, the faithful servant and friend of the pious Oberlin, who transformed a miserable and ignorant hamlet of the Vosges chain into an industrious, happy, and comfortable village; from her originated an institution for the children of the poor laborers, from which arose the infant schools of England and France; to this noble object this peasant girl consecrated her property, youth, and health, refusing all compensation; in this discourse Cuvier gives utterance to the noblest sentiments.—Cuvier was quite as eminent a legislator as naturalist, though less known in the former capacity; he was always an advocate for progress both in matters of government and of education; and, as royal commissary, councillor of the university, member of the state council, and president of the committee of the interior, he introduced beneficial changes in the municipal and provincial laws, and in public instruction. His language, both written and spoken, was clear, forcible, precise, animated, and frequently rising to the highest eloquence. The benignity and noble expression of his countenance was remarkable. In private, he was kind, affable, and ready to communicate information; his manners, though dignified and sometimes stately in company, were always courteous; he was very fond of the society of young persons and females. He had the greatest love for order and regularity, without which he never could have accomplished his manifold duties; he rarely allowed himself to be disturbed during the hours he invariably set aside for study, but during his hours of audience he was accessible to everybody. He generally rose at 7, and made his preparations for the day's work till 10, when he breakfasted; then came the routine of his daily occupation at the council, in the *jardin*, in his library, until dinner, at which occurred the happiest reunions of his family and intimate friends. Always busy himself, he never suffered any one about him to be idle; after the fatigue of a well-spent day, it was his delight to enter into conversation, or, throwing himself on a sofa, to hide his eyes from the light and listen to the readings of his wife and daughters. Very sensible to kindness, he was equally so to ingratitude; his benevolence was proverbial, and his social conduct perfectly free from conceit, resentment, and sarcasm; if, by his natural quickness and irritability of temper, he thought he had injured the feelings of any one, he was never happy until he had repaired the fault. With his other accomplishments, he was an expert draughtsman; many of his plates were drawn by himself, and he left a large collection of designs intended to illustrate his never finished great work on comparative anatomy. The disinterestedness of Cuvier's character is shown not only by the acts of his life, but by the small fortune he left at his death; having filled offices of the highest trust, which he might have turned to his pecuniary advantage, he left only the sum of about $20,000, and a library which cost him a similar sum. He desired to be buried without ceremony, but such a man could not die without the public manifestation of sorrow and respect, and his funeral was accordingly attended by the first men of the day. Cuvier was a member of the learned societies of all countries, for all held themselves as highly honored in enrolling his illustrious name among their number. His library was purchased by government, and given to various institutions, but principally to the *jardin des plantes*.—When we consider the number of offices which he held, and whose duties he conscientiously performed, any one of which, after his death, was considered sufficient for a man of great talent, and some of which could not be filled by as competent a person, we are able to form some idea of the varied acquirements, of the unceasing industry, of the wonderful memory, and of the transcendent ability of Cuvier. There never has been a man, before or since his day, who combined so many faculties of the highest order of development for the advancement of the natural sciences; his influence will be felt through all time, and in all lands where nature is studied either for pleasure or instruction; his example will be for ever looked up to as one of the most striking in the annals of history, of entire devotion to lofty principle, disinterested labor for the advancement of knowledge, and constant endeavor to promote the interests of his country. By universal consent, he is regarded as one of the best of men, most brilliant of writers, soundest of thinkers, most far-sighted of philosophers, purest of statesmen, and the greatest naturalist of modern times.—Frédéric, brother of the preceding, born at Montbéliard, June 28, 1773, died in Strasbourg, July 24, 1838. With a strong love for the science of mechanics, he abandoned his college studies, and became the apprentice of a clock-maker; and would doubtless have been an eminent mechanician, had not his invitation to Paris in 1797 by his brother, who then had become famous, opened his eyes to a new world of natural science. He was employed by his brother

in preparing the descriptive catalogue of the skeletons in the collection of comparative anatomy at the *jardin des plantes;* this was the beginning of his work on the teeth of mammals, published in 1825, which led to many important changes in the natural arrangement of this class, especially in the subdivision into genera, most of which are now adopted in zoology. In 1804 he assumed the direction of the menagerie at the *jardin des plantes*, a situation which enabled him to study the habits, instincts, and intelligence of animals; the results of his researches are given in his *Histoire naturelle des mammifères*, published in 1818–'37. Geoffroy St. Hilaire was associated with him in this work, of which 70 *livraisons* in folio appeared, describing in a simple, charming, and elegant style more than 500 animals under his charge, with anecdotes illustrating their habits and intelligence. Many of the separate papers were first printed in the *Annales du muséum d'histoire naturelle.* While Descartes and Buffon denied all intelligence to animals, not perceiving the limit between the human intellect and the lower intelligence of other mammals—while Condillac and George Leroy, on the contrary, accorded to animals even the highest intellectual operations, confounding instinct with intelligence—Frédéric Cuvier drew the line between the intelligence of different orders, tracing it from the lowest rodents through ruminants, pachyderms, and carnivora, to the quadrumana. He found the greatest intelligence in the orang outang, but this decreased as the animal grew older, the docility, intelligence, and cunning of the young being replaced in the adult by the intractability and stupidity of a disgusting brute. Taking the beaver and the dog for examples, he showed the difference between instinct and intelligence. The beaver, a rodent, of an order which manifests the least intelligence, builds its dam and habitation in a most remarkable manner; but young animals, removed from their parents and placed in comfortable houses, have yet shown the same disposition to build, impelled by a blind internal power, instinct, as distinguished from intelligence. Instinct acts of necessity, invariably in the same manner, without adaptation to circumstances, without education, and for a single limited purpose; thus the beaver builds his dam. Intelligence, on the contrary, chooses its means, modifies its acts at will, learns from experience, and follows no irresistible impulse; the dog and the horse understand and obey their master because it pleases them so to do, but they may disobey if they choose, and may apply their acquired knowledge to a great variety of purposes. With this understanding of the two forces, the actions of animals can never be placed above the intelligent acts of man. Animals receive impressions, remember them, associate them together, and draw from them conclusions which influence their conduct; but man alone, according to him, reflects upon his own sensations, experience, and thoughts. This power of reflection draws the line between the intelligence of man and that of animals. He first showed that domesticity in animals depends on their sociability, being not a change but a development of their natural condition. Man found animals living in society, and he made such domestic; we may tame the solitary and fierce bear, lion, and tiger, but we cannot domesticate them. This view is capable of useful application in increasing the number of domestic species for agricultural and industrial purposes. F. Cuvier, in 1810, was nominated inspector of the academy of Paris, and in 1831 inspector-general of the university. He devoted himself to these new duties with the same zeal and conscientiousness which characterized his former labors, and was a firm advocate for the introduction of the study of natural history into schools and colleges by text books shorn of learned technicalities, and graduated according to the educational standing of the classes. His character was amiable, his deportment unassuming, his speech and acts displaying a truthfulness and gentleness which won the love and confidence of all; he never thought of his own fame, but was keenly sensitive for that of his brother, for whom he ever felt the most devoted friendship. In 1827 he was elected professor of comparative physiology at the *jardin des plantes*, a chair created for him by the minister of public instruction. While on a tour, for the annual inspection of the colleges required by his office, and when about to deliver a course of lectures on natural history, he was seized with paralysis at Strasbourg, of which he died. There is a striking similarity between his death and that of his brother; both, so intimately united in life, died of the same disease, at the same age, under similar circumstances, with the same serenity of mind and intrepidity of soul. His last words were: "Let my son place upon my tomb this inscription: 'Frédéric Cuvier, brother of Georges Cuvier,'" showing that even in his last moments love and admiration for his deceased brother predominated in his mind. Beside the 2 great works above mentioned, and many memoirs in the *Annales du muséum d'histoire naturelle*, Frédéric Cuvier wrote numerous articles in the *Dictionnaire des sciences naturelles*, and *L'histoire des cétacés*, in the *Suites à Buffon*, in 1836. His name was Georges Frédéric, though the first name was never applied to him, that being always given to his more celebrated brother.

CUXHAVEN, a town with a fine harbor at the mouth of the river Elbe in Germany, on its left bank, belonging to the territory of Hamburg, district of Ritzebüttel, about 58 m. from the city of Hamburg; pop. 1,600. It contains sea baths, founded in 1815; a beacon tower of fine construction, and a well regulated pilot establishment, which has superseded the use of the Heligoland fishermen for the piloting of vessels into the Elbe river. It seems to be destined to become for Hamburg what Bremerhaven is for Bremen—a harbor for sea-going vessels of large

tonnage, of which 100 at present may be safely accommodated, but far more in case of emergency. Its use will increase if the Elbe should continue to lose its depth, as it has been doing for 30 years past. In 1849 and 1850 a portion of the German navy was stationed here, and had a contest with the Danish navy, resulting in the breaking up of the Danish blockade.

CUYABA, or CUIABA. I. The capital, since 1820, of the Brazilian province of Matto Grosso, lat. 15° 26′ S., long. 56° W., near Cuyaba river; pop. about 15,000. It is irregularly built, and the houses are mostly constructed of earth or clay. It contains several churches, an imperial hospital, a lazaretto, and various educational institutions, is the seat of the bishop of the diocese of Matto Grosso, and the centre of an important gold-mining district. II. A river of Brazil, which rises in the district of Diamantino, among the Parecis mountains, in lat. 13° 12′ S., and flows with a circuitous course, but in a general southerly direction, until it joins the Porrudos, or San Lourenço, on its right bank, in lat. 17° 20′ S., long. 56° 40′ W. It forms an important channel of communication, and is of especial advantage to the town of Cuyaba, although for 60 miles below that place its current is extremely rapid and headlong. Above the town it is navigated by canoes, but the course of the river is here much broken by rapids.

CUYAHOGA, a N. E. co. of Ohio, bordering on Lake Erie, and intersected by Cuyahoga river, from which it is named; area, 426 sq. m.; pop. in 1850, 48,099. The surface is level, and the soil fertile. In 1850 the productions amounted to 222,915 lbs. of wool, 841,943 of butter, 37,560 tons of hay, 362,102 bushels of corn, and 193,132 of oats. Sandstone is abundant in this county, and is much used for grindstones and for building. The principal internal improvements are a canal and 6 railroads, connecting Cleveland, the capital, with Erie, Cincinnati, Toledo, Columbus, Zanesville, Youngstown, and Pittsburg.

CUYAHOGA, a river of Ohio, rising in the N. E. part of the state, and emptying into Lake Erie at Cleveland. At a place called Cuyahoga Falls, in Summit co., it descends 200 feet in about 2½ miles. Its course is very circuitous, and it affords good water power.

CUYP, or KUYP, ALBERT, a Dutch painter, born at Dort in 1606, died after 1672. His father, Jacob Gerritse Cuyp, a painter of landscapes and animals, and one of the founders of the academy of St. Luke in Dort, was his first and probably his only master. A strict Calvinist and devoted to his art, he passed the greater part of his time at a small country seat near Dort, where his room, the walls of which are covered with designs for which he rarely received orders, is still shown to visitors. There is even no record of his death, although, as appears from a list of the burghers of Dort, he was living in 1672. His pictures were singularly neglected for many years after his death, and it is said that down to the year 1750 there is no example of any one of them selling for more than 30 florins, or about $12. England seems to have been the first to appreciate their merits, for shortly after this time the demands of English collectors caused a considerable rise in their value; and Horace Walpole, in a letter written in 1774, mentions with astonishment that a picture by Cuyp had just been sold for £290. Within the last 30 years they have frequently brought from 1,000 to 1,500 guineas, and are to be found in great numbers in private and public galleries in England. The range of subjects which Cuyp attempted was extensive. He painted scenes on the Maas river, in the neighborhood of Dort, with herds of cattle and horsemen, cavalry skirmishes, horse fairs, sea pieces, moonlights, winter scenes, and interiors, all of which show a high degree of excellence. Some of his drawings, heightened by water colors, are gems of art. His best pictures are his landscapes, to attain perfection in which he was accustomed to make studies in the open air at all hours of the day. Dr. Waagen has summed up his artistic qualities as follows: "In loftiness of conception, knowledge of aërial perspective, with the greatest glow and warmth of serene atmosphere, Cuyp stands unrivalled, and may justly be called the Dutch Claude. In the *impasto*, the breadth and freedom of execution, he greatly resembles Rembrandt." Unlike most other Dutch painters, he did not finish his pictures very elaborately, but strove to impress them with the stamp of intellectual rather than of manual labor.

CUZCO, a central department of Peru, lying chiefly between lat. 13° and 15° S., and long. 70° and 73° W., comprehending all the region drained by the affluents of the Pilcomayó and the upper course of the Apurimac, and divided into 11 provinces; area, about 45,000 sq. m.; pop. about 350,000, the majority of whom are Indians. The department abounds in mines, which, however, are not efficiently worked. The principal objects of trade are woollen and other goods, and leather manufactured by the inhabitants.—The capital, Cuzco, is situated in a valley about 11,000 feet above the level of the sea, between the rivers Apurimac and Urubamba, lat. 13° 30′ 55″ S., long. 72° 4′ 10″ W.; pop. 50,000, of whom about 15,000 are Indians, distinguished for their industry. It is the seat of the provincial authorities and of a bishop, contains a fine cathedral, several convents, a university, 2 colleges, a mint, and trades in ivory, iron, timber, and in the local manufactures, consisting of cotton and woollen goods, leather, ingenious embroideries and carved furniture, &c. According to the national tradition it is the most ancient city of Peru, and the source of Peruvian civilization is traced to the valley of Cuzco. In ancient times it was the royal residence, adorned with spacious dwellings of the great nobility; it was called the holy city; the festivals of religion were celebrated there, and it contained a temple of the sun (parts of which are still to be seen), richly adorned with gold and silver, to which pilgrims resorted from the

furthest borders of the empire, and which was the most magnificent structure in the new world. Beside the temple, there were from 300 to 400 inferior places of worship, and the pilgrimage to this Peruvian Mecca was as binding upon the Indian noble as that in the East upon the Moslem. Toward the N. it was defended by a spur of the great Cordillera, on which rose a strong fortress, a stupendous specimen of Cyclopean architecture, the ruins of which are still visible. Twenty thousand men are said to have been employed on this structure, and 50 years consumed in building it. In 1532 Atahuallpa's generals took possession of the famous city, and in the following year (probably on Nov. 15) Pizarro made his entrance into the Peruvian capital. The population of the city was computed at that time by one of the Spanish conquerors at 200,000, and that of the suburbs at as many more; but although this estimate is probably exaggerated, all accounts agree in the remarkable prosperity and beauty of the city, which surpassed all that the Spaniards had yet seen in the new world. Subsequently the neighborhood of Cuzco frequently became the theatre of chivalrous combats between the Spaniards and the incas, which, according to Prescott, "wanted only the song of the minstrel to throw around it a glory like that which rested on the last days of the Moslems of Spain." The rapacity of the Spanish conquerors soon stripped Cuzco of its ancient splendor; but the appearance of the city and the structure of the houses still recall the glorious era of the incas, and the remarkable highway which led over the mountains from Cuzco to the northern part of Peru is still in existence, and is called the incas' road. Cuzco, along with the rest of Peru, proclaimed its independence of Spain in 1821. On Aug. 9, 1835, a victory was achieved there by the Bolivian Gen. Santa Cruz over Gamarra, the commander of the Peruvian forces.—See Rivero and Tschudi, *Antigueda des Peruanes* (Vienna, 1852); P. de Carmoy, *D'Aréquipa à Cuzco, souvenirs de voyage dans l'Amérique du Sud* (Paris, *Revue contemporaine*, 1857); Prescott's "History of the Conquest of Peru" (Boston, 1847); and Markham's "Cuzco and Lima," with plates (London, 1856).

CYANOGEN (Gr. κυανος, blue, and γενναω, to produce), a principal ingredient in Prussian blue, is a compound gas consisting of 2 atoms of carbon and one of nitrogen, and is properly designated as a bicarburet of nitrogen, the chemical equivalent of which is 26. It is of particular interest, being the first instance known of a compound body performing the part of an element in its combinations. It was discovered by Gay-Lussac in 1815, and may be obtained by decomposing the cyanide mercury in a small glass retort by the heat of a spirit lamp. The mercury sublimes, and the gas passes over; a dark colored substance like charcoal remains in the retort, which appears to have the same composition as the gas. It may also be obtained by heating nitrogenous bodies, as woollen rags, in a close vessel together with potash or carbonate of potash. The gas as it is produced combines with the potassium to form a cyanide. Cyanogen is a colorless gas of specific gravity 1.86, possessing a strong pungent odor similar to that of the kernels of peach stones or of prussic (hydrocyanic) acid. It is inflammable, burning with a blue and purple colored flame, and passing into carbonic acid gas and nitrogen. By the cold of —22° F. or the pressure of 3.6 atmospheres it may be liquefied, forming a thin colorless fluid. It is absorbed by water, but is soon decomposed in this condition, and forms compounds with the water possessing acid reaction, beside many others of the different elements variously combined. Exposed to a high temperature, the gas is not decomposed; but mixed with 2 volumes of oxygen, it explodes violently at a red heat, or by the electric spark, separating into carbonic acid and nitrogen. The properties of cyanogen in relation to other bodies are analogous to those of chlorine, bromine, and iodine. It forms an acid with hydrogen (hydrocyanic acid), and binary compounds with the metals, cyanides, or cyanurets, which readily combine among themselves or with the chlorides and sulphurets, forming double cyanurets, chlorocyanurets, and sulphocyanurets. With oxygen cyanogen unites to form several acids, as cyanic acid, CyO,HO; fulminic acid, $Cy_2\ O_2\ 2HO$; and cyanuric acid, $Cy_3\ O_3\ 3HO$. The first is a volatile colorless fluid, with the odor of acetic acid. Its salts are cyanates.

CYANOMETER, an instrument invented by Saussure for measuring the intensity of the tint of the atmosphere. (See Meteorology.)

CYAXARES I. and II. See Media.

CYBELE, or Rhea, a Greek and Roman divinity, who is said to have been the daughter of Cœlus and Terra, the wife of Saturn, and the mother of all the other gods and goddesses. Saturn insisting on devouring his children, the goddess mother, when she found herself pregnant with Jupiter, proceeded, according to the advice of her parents, to Lyctus in Crete, where she gave birth to her son. The moment the infant was born, certain pious youths of the neighborhood assembled round him with clashing arms and loud sounding instruments of music, and drowned the child's cries, while his crafty mother hied away to offer a stone wrapped up like a child to her husband as a substitute for the babe. The stratagem was successful, and Saturn swallowed the stone. The infant in the meanwhile was nursed by beautiful shepherd youths, whom Cybele rewarded for their devotion by initiating them into the mysteries of her worship, and appointing them to be priests and ministers at her altars. According to this myth, then, Crete was the original seat of Cybele's worship. That worship, wherever established, was of the same Bacchanalian character. Her priests in Phrygia were called corybantes; in Crete, curetes; at Rome, galli; but everywhere they must be both youths and eunuchs; everywhere they must cease to be

men ere they could be ministers of Cybele. Though the worship of this goddess had prevailed from very early times in Greece and Asia, where it may be traced under various names, in various countries, yet it was not introduced at Rome till the period of the second Punic war. Then it was that the image of Cybele or Rhea was brought from Pessinus, in Galatia, that a temple was raised to her on the Palatine hill, and that the festival of the Megalesia was instituted in her honor by the Roman matrons. In works of art Cybele is usually represented seated on a throne with a mural crown on her head, from which a veil is suspended. Lions are frequently seen crouching on the right and left of the throne, and occasionally she appears riding in a chariot drawn by lions.

CYCLADES (Gr. κυκλος, a circle), a group of nearly 60 small islands in the Grecian archipelago or Ægæan sea, N. of Candia, forming one of the 10 nomes or districts of modern Greece; area, 1,216 sq. m.; pop. in 1855, 139,337. The ancient Greeks gave this name to these islands in the belief that they formed a circle around the holy island of Delos, while all the other islands within the same sea were called Sporades, or scattered islands, from their being scattered in every direction. In fact, these islands form 3 distinct, nearly straight and parallel lines running from N. W. to S. E., of which the first, comprising Zea (anc. Ceos), Thermia (Cythnus), Serpho (Seriphus), Siphanto (Siphnus), and Polycandro (Pholegandros), seem to have in antediluvian times formed one mountain chain, connected with the mountains of Attica on the N., and by the island Melos with the western mountains of Candia on the S.; the 2d, comprising Andro (Andros), Tino (Tenos), Mycono (Myconus), Naxia (Naxos), Amorgo (Amorgus), and Stampalia (Astypalæa), another mountain chain connected with that of Eubœa and the S. W. promontory of Asia Mior; the 3d, lying between the 1st and 2d, and comprising Chiura (Gyarus), Syra (Syros), Paro (Paros), Antiparo (Antiparos), Nio (Ios), and Santorin (Thera), may have had a connection with the E. end of Candia. However this may be, they have the same formation, climate, and products, and even the same history, with the regions of these continental chains. Santorin is still, what several of the other islands once may have been, a volcanic island of very remarkable phenomena. Paro and Antiparo are renowned for their stalactite caves. These islands, once subject to Athens, and the basis of its maritime power, were among the first to shake off the Turkish yoke. The merchant navy of the Cyclades in 1855 consisted of 1,335 vessels, tonnage 156,148. Silk is raised in the islands of Andro and Tino, the former producing, in 1856, 250,000 lbs., and the latter 60,000 lbs. Syra, the capital, is a great emporium of the Levantine and Mediterranean trade.

CYCLE (Gr. κυκλος, a circle), any period of regularly recurring events. Thus 28 years is called a solar cycle, being a period at the end of which the same day of the week falls again upon the same day of the year. The lunar cycle is a period of 19 years, at the end of which the new moon occurs again on the same day of the month.

CYCLOID, the curve traced by a point in the circumference of a circle, rolling on a straight line. Next to the conic sections, the cycloid is one of the most interesting and valuable of curves. It is the curve in which a falling body will reach the bottom in the same time from whatever height it may start; it is the curve in which a body will descend from one point to another in the least time; and it possesses other remarkable properties.

CYCLOIDS, an order of bony fishes, established by Agassiz, comprising those with soft circular scales, like the salmon, cod, and herring.

CYCLONE, a storm of wind which moves in immense whirls, and at the same time sweeps onward over the surface. Cyclones are usually 200 to 300 m. in diameter, sometimes more than 1,000 m. Their central point is calm, and this moves forward from 2 to 40 m. per hour. These storms originate outside the equatorial belt between the tropics, and move toward the poles. In the southern hemisphere the rotation is in the same direction with the hands of a watch placed with the face upward; in the northern, the direction is reversed. (See Hurricane.)

CYCLOPÆDIA, or Encyclopædia (Gr. κυκλος, a circle, and παιδεια, education), originally the cycle of the 7 liberal arts and sciences which constituted, with the ancients, the course of education for the higher class of citizens, viz.: grammar, arithmetic, geometry, music, astronomy, dialectics, and rhetoric. Thus Quintilian mentions it as the orb or full circle of learning: *Orbis illa doctrinæ quam Græci* εγκυκλοπαιδειαν *vocant.* It commonly designates a summary of human knowledge, either in one or in all departments, arranged either systematically according to the logical connection of topics, or lexicographically according to the alphabetical succession of terms; and is therefore distinguished as either general or special, systematic or alphabetical. Speusippus, the nephew and disciple of Plato, is usually accounted to have written the first cyclopædic work, under the title of Διαλογοι των περι την Πραγματειαν Ὁμοιων, which has not been preserved. The work of Aristotle on the sciences (Περι Επιστημων), the lost books of Varro entitled *Rerum Humanarum et Divinarum Antiquitates*, and the *Historia Naturalis* of Pliny, approached to the character of cyclopædias. The last is a vast compilation, treating, as Pliny says in his preface, of 20,000 matters of importance, drawn from about 2,000 volumes. Astronomy, mathematics, natural philosophy, botany, mineralogy, medical science, arts, agriculture, all came within the compass of his researches. His work has the merit of showing the progress which science and the arts had made down to the time at which he wrote. The collections of Stobæus, Suidas, and especially of Marcianus Capel-

la (about A. D. 480), and of Isidorus Hispalensis (about A. D. 636), may also be regarded as works of the same character. The *Satyra* of Capella is a confused exposition of the 7 liberal arts, and the *Origines* of Isidorus furnishes a complete knowledge of the state of mental culture at the epoch of its publication. Cyclopædias were not uncommon in the middle ages, under the title of *Summæ* and *Specula*. One of the most celebrated of these is the *Speculum Historiale, Naturale, et Doctrinale*, by the indefatigable Dominican, Vincent of Beauvais (Vincentius Bellovacencis, died in 1264), to which a *Speculum Morale*, by an unknown author, was afterward added. This repository of scholastic science, consisting mostly of extracts from the works of writers of the time, is particularly valuable for the light which it sheds on the literary history of that period. The first edition was published at Strasbourg (7 vols. fol., 1473–'76), and the last at Douay (4 vols. fol., 1624). Of mediæval particular cyclopædias, or complete treatises on special subjects, the *Summa Theologiæ* of Thomas Aquinas is an eminent example. Alfarabius, one of the great lights of the Bagdad school, enriched the 10th century with a cyclopædia, which, on account of a systematic subdivision of the various branches of knowledge, might be justly compared to works of the same denomination belonging to the literary history of later centuries. Nothing, however, is known of this production except the notice Casiri gives of it in his *Bibliotheca Arabico-Hispana Escurialensis*, where it is described as a work *ubi scientiarum, artiumque liberalium, synopsis occurrit, una cum accurata et perspicua carum notitia, definitione, divisione, methodo.* In the 16th century several works of a cyclopædic character appeared, such as the *Margarita Philosophica* of Reisch (Freiburg, 1503, and Basel, 1583); the *Cyclopædia* of Ringelberg (Basel, 1541), a small thick volume, consisting of concise treatises on grammar, logic, and other branches; the *Encyclopædia seu Orbis Disciplinarum Epistemon* of Scalich (Basel, 1559); and the *Idea Methodicæ et Brevis Encyclopædiæ, seu Adumbratio Universitatis*, by Martini (Herborn, 1606). These were followed by Alsted's more elaborate work, *Cursus Philosophici Encyclopædia* (4 vols., Herborn, 1620; afterward published as *Scientiarum Omnium Encyclopædia*, at Herborn in 1630, and at Lyons in 1649), which is commonly referred to as the most celebrated of the early cyclopædias. Its author, Johann Heinrich Alsted, a professor of philosophy at Weissenburg in Transylvania, was one of the divines who attended the synod of Dort. The plan of his work is not unlike that of Ringelberg, but the subjects it embraces are more varied, and each is more elaborately treated. It consists of 35 books, of which the first 4 contain an explanation of the nature of the various subjects discussed in the rest. Then follow successively 6 on philology; 10 on speculative, and 4 on practical philosophy; 3 on theology, jurisprudence, and medicine; 3 on the mechanical arts; and 5 on history, chronology, and miscellaneous topics. This work was held in high estimation till the close of that century. Leibnitz mentions it, in the early part of the next, in respectful terms, accompanied with an earnest wish that some of the learned would either join in remodelling and improving it, or in composing an entirely new work of the same kind. The observations of this illustrious philosopher show that he had reflected much on the objects of such an undertaking, and that he considered a cyclopædia as a species of publication calculated to be eminently useful to mankind. In the early part of the 17th century appeared also the *De Dignitate et Augmentis Scientiarum* (1605), and the *Novum Organum Scientiarum* (1620), of Lord Bacon; works not, indeed, voluminous, but rich in deep and acute thinking, and in which he laid the foundation of a logical arrangement of the sciences. After his time appeared a multitude of cyclopædias, designed for the instruction of the young and uninformed. Such were the *Science des personnes de la cour, de l'épée, et de la robe*, by Chevigny (5th ed. by Limiers, 4 vols., Amsterdam, 1717); and the *Pera Librorum Juvenilium*, by Wagenseil (5 vols., Altdorf, 1695). Treatises, also, written with the object of bringing universal knowledge into systematic order became more numerous. This was the aim of the *Polyhistor* of Morhof (Lübeck, 1688), and of the *Cours d'études* of Condillac. In Germany, Sulzer endeavored to show the essential connection of all branches of learning in his *Kurzer Inbegriff aller Wissenschaften* (Berlin, 1756); and his classification was adopted and improved by many succeeding cyclopædists, as J. M. Gesner, in his *Primæ Lineæ Isagoges in Eruditionem Universam* (Göttingen, 1774), Reimarus (1775), Adelung (1778), Reuss (1783), Klügel (1788), Buhle (1790), and Büsch (1795). Eschenburg, in his *Lehrbuch der Wissenschaften* (Berlin, 1792), was the first who attempted to construct a cyclopædia of the sciences according to the principles of the Kantian philosophy. His ideas were elaborated by Habel, Rüf, Strass, Hefter, Burdach, and Krauss. Complete logical classifications were made also by Krug, in his *Versuch einer systematischen Encyklopädie der Wissenschaften* (Wittenberg, 1796–'98); by Schmid, in his *Allgemeine Encyklopädie und Methodologie der Wissenschaften* (Jena, 1811); by Jäsche, in his *Einleitung zu einer Architektonik der Wissenschaften* (Dorpat, 1816); by Kronburg, in his *Allgemeine Wissenschaftslehre* (Berlin, 1825); by Gruber, in the introduction to the second volume of Ersch and Gruber's *Encyklopädie;* and by Kirchner, in his *Akademische Propädeutik* (Leipsic, 1842).—Although the lexicographic arrangement had been anciently employed by Suidas, it was but slowly brought into use after the revival of learning. It was long before the idea occurred that it might be used as the basis of a universal repertory of human learning; and still longer before it was employed as the vehicle of general treatises similar to those of the early systematically arranged cyclopædic works. The first lex-

icographic cyclopædias contained notices only of celebrated persons and places, as the *Dictionarium Proprium Nominum Virorum, Mulierum, Populorum, Idolorum, Urbium, Fluviorum, Montium*, &c., by Robert Stephens (Paris, 1544); and the *Dictionarium Historicum et Poeticum*, by Charles Stephens (Paris, 1553; enlarged by R. Lloyd, Oxford, 1671, and London, 1686). The historical dictionary of Moreri (Lyons, 1673), and the historical and critical dictionary of Bayle (Rotterdam, 1697), were the most important of many biographical cyclopædias of this period, the latter treating also incidentally many scientific questions. Of larger compass and of less thorough execution were the *Lexicon Universale Historico-Geographico-Chronologico-Poctico-Philologicum*, by J. J. Hofmann (Basel, 1677; supplement added, 1683; new ed. Leyden, 1698); and the *Bibliotheca Universalis Sacro-Profana*, by Coronelli (Venice, 1701), which was intended to form 45 volumes, but was continued only into the letter C in 7 volumes.—The first English cyclopædia was the "Lexicon Technicum, or an Universal Dictionary of the Arts and Sciences," by John Harris (2 vols., London, 1706–'10). It explained both the terms of art and the arts themselves; but though professing to be universal, it was in fact limited almost exclusively to the mathematical and the physical sciences, and hence was far from fulfilling its intended purpose. The "Cyclopædia" of Ephraim Chambers (2 large fol. vols., London, 1728) was also termed a general dictionary of the arts and sciences, and was the first work in which knowledge was subdivided under appropriate heads, which were placed in alphabetical order, and treated so as to exhibit at the same time a complete account of the various branches and of their connections and dependencies. "His view," he says, "was to consider the several matters, not only in themselves, but relatively, or as they respect each other; both to treat them as so many wholes, and as so many parts of some greater whole, their connection with which to be pointed out by reference; so that by a course of references from generals to particulars, from premises to conclusions, from cause to effect, and *vice versa*, *i.e.*, from more to less complex, and from less to more, a communication might be opened between the several parts of the work; and the several articles be in some measure replaced in their natural order of science, out of which the alphabetical order had removed them." Yet Chambers remained far from attaining his object, for the ramifications are so varied and minute that one would seek in vain in his volumes for any thing like a substitute for separate treatises, or for more, under many heads, than short and unconnected elucidations, or mere definitions and incomplete explanations. On mathematical subjects, conclusions are given without demonstration or experimental details. But with all its defects, whether of plan or execution, this work of Chambers must be regarded as the production of a mind of superior compass and vigor, and as the fruit of remarkable research and diligence. Five editions of it were published within 18 years; while upon the continent of Europe it produced no less effect than in England. It was translated into French and Italian, and its plan was highly applauded in the preliminary discourse of the great French *Encyclopédie*. Its success gave rise to a number of similar works, mostly modelled after it. The first of these was the "New and Universal Dictionary of Arts and Sciences," by John Barrow (1 vol. fol., London, 1751; supplementary vol. added, 1754). Its only recommendation, as compared with its predecessor, consisted in an enlarged number of articles on mathematical subjects, on the mechanical arts, and on naval affairs; to make room for which, church history and all scholastic topics were excluded. This was followed, in 1754 (2d edition in 1764), by a "New and Complete Dictionary of Arts and Sciences," comprised in 4 large 8vo. vols., written, according to the title page, "by a society of gentlemen," and commonly called, from the name of its publisher, "Owen's Dictionary." It is distinguished by the general brevity of its articles, a quality which enabled its compilers to widen its range in the departments of geography, commerce, and natural history. In 1766 was published the "Complete Dictionary of Arts and Sciences," in 3 vols. fol., a work compiled under the joint direction of Henry Croker, Thomas Williams, and Samuel Clark; the theological, philosophical, and critical branches being edited by the first; those of anatomy, medicine, and chemistry, by the second; and the mathematical by the last. Notwithstanding this division of labor, the work was not marked either by excellence in the respective departments, or method in their arrangement. In 1745 Dr. De Coetlogon published in London a "Universal History of Arts and Sciences," which was largely composed of complete treatises on distinct arts and sciences, and may therefore have suggested the plan of the "Encyclopædia Britannica." The latter work made its first appearance in Edinburgh, in 1771, in 3 quarto volumes, and was distinguished from those previously published in England less by its execution than by its more philosophical method. Instead of attempting to elucidate the sciences by a number of separate articles corresponding to their technical titles or sections, introduced in the order prescribed by the alphabet, it treated each science completely in a systematic form under its proper denomination; the technical terms and subordinate heads being also explained alphabetically, when any thing more than a reference to the general treatise was required. This plan was prosecuted upon a wider scale, and with more maturity of execution, in the subsequent editions. The objects aimed at in the early cyclopædias were in this way reconciled with the lexicographic arrangement, while its adaptation to particular topics was in no respect impaired. The editor and principal compiler of this first edition was

William Smellie, a scholar particularly conversant with natural history, although by profession a printer. The 2d edition (extended to 10 vols., 1776–'83) was chiefly remarkable for the addition of the two popular departments, history and biography. The 3d edition (18 vols., 1786–'97; a supplement of 2 vols. was added afterward) contained valuable contributions in speculative philosophy, ancient erudition, and physical science, from the pens of Dr. Gleig, Dr. Doig, and Prof. Robison, which attracted general attention, and gave to the work a new and more dignified aspect. This edition of the "Encyclopædia Britannica" was republished in Philadelphia, by Thos. Dobson (21 vols. 4to., including the supplement, 1798–1803). A 4th edition, increased to 20 vols., was completed in 1810, under the able superintendence of Dr. James Millar. This was enriched with the contributions of Prof. Wallace on pure mathematics. A 5th and a 6th edition, which the increasing demand for the work required, soon followed; these, however, were little more than reprints of the former. While these were in progress, a supplement extending to 6 vols. made its appearance, edited by Macvey Napier, and published by Archibald Constable. The first half volume was produced in 1815, under the sanction of the name of Dugald Stewart, as the author of the first of those preliminary dissertations on the history of the sciences, which, in a more complete state, so greatly adorn and recommend the latest edition. Enriched as it was by contributions from the most eminent writers and scholars of the day, including the distinguished philosophers of France, Arago and Biot, the work rose rapidly in public favor. The copyrights of the previous editions having passed into the hands of A. and C. Black of Edinburgh, these enterprising proprietors immediately commenced the publication of a new and enlarged edition, under the editorial supervision of Prof. Napier (21 vols., including the late supplement, a general index, and numerous engravings, 1830–'42). The 8th and last edition, with extensive improvements and additions, and an introductory volume of dissertations, was commenced in 1853, and published jointly by A. and C. Black of Edinburgh, and Little and Brown of Boston. It is still in progress. For this, as for the preceding editions, articles have been furnished by the most distinguished contemporary authors.—The following is a summary notice of the principal English and American cyclopædias that have appeared since the commencement of the last quarter of the 18th century, arranged in the chronological order of their publication:

1. New Dictionary of Arts and Sciences, or an Universal System of Useful Knowledge. By E. Middleton and others. 2 vols. folio. London, 1778.
2. New Royal Encyclopædia. By W. H. Hall. 3 vols. folio. London, 1789. (A second edition of this work, enlarged by J. Lloyd, was published in 1796, in 3 vols. folio, with plates.)
3. The Encyclopædia Londinensis, or Universal Dictionary of Arts, Sciences, and Literature. Projected and arranged by John Wilkes. 24 vols. 4to. London, 1797–1829.
4. The English Encyclopædia, or a Dictionary of Arts and Sciences. 10 vols. 4to. London, 1801.
5. Rees's Cyclopædia, or Universal Dictionary of Arts, Sciences, and Literature. 39 vols. with 6 vols. of plates. London, 1802–'19. (This work, comprising the various articles in Chambers's Cyclopædia, with additions and improvements, was far more extensive than any similar work that had preceded it in England, being particularly complete in the technical department. An American edition was published at Philadelphia, 47 vols. 1810–'24, which, proving unsuccessful from the magnitude and difficulty of the enterprise, was at last disposed of by lottery.)
6. Gregory's Dictionary of Arts and Sciences. 2 vols. 4to. London, 1806. (A compilation formerly in high repute, of which an American edition was published, 3 vols. 4to., Philadelphia, 1815–'16.)
7. Nicholson's British Encyclopædia, illustrated with engravings by Lowry and Scott. 6 vols. 8vo. London, 1809. (The third American edition of this popular work was published at Philadelphia, 12 vols. 8vo., 1819.)
8. The Imperial Encyclopædia. By W. M. Johnson and T. Exley. 4 vols. 4to. London, 1809–'14.
9. The Edinburgh Encyclopædia. Conducted by Sir David Brewster. 18 vols. 4to. Edinburgh, 1809–'30. (This important work was especially rich in its scientific department, and an American edition of it, improved by the addition of numerous articles relative to the American continent, was published at Philadelphia in 1832.)
10. The Encyclopædia Metropolitana, or Universal Dictionary of Knowledge, on an Original Plan, comprising the twofold Advantage of a Philosophical and an Alphabetical Arrangement, with appropriate Engravings. Edited by Edward Smedley, Hugh James Rose, and Henry John Rose. 25 thick vols. with 3 additional vols. of plates and one of index. London, 1815–'45. (The divisions of this work, which follow a system of universal knowledge projected by S. T. Coleridge, are as follows: Vols. 1, 2, pure sciences; vols. 3–8, mixed and applied sciences; vols. 9–13, history and biography; vols. 14–25, a miscellaneous lexicon. A cabinet edition is in process of publication in small octavo volumes. In this large collection are contained many complete treatises of great value, as the "Science of Method" of Coleridge, the "Logic" and "Rhetoric" of Archbishop Whately, portions of Roman history by Dr. Arnold, and works on the history of moral and metaphysical philosophy by F. D. Maurice.)
11. The Encyclopædia Edinensis. By James Millar. 6 vols. 4to. Edinburgh, 1816.
12. The Encyclopædia Perthensis, with Plates. Attributed to Miller. 23 vols. 8vo. London, 1816.
13. The London Encyclopædia, or Universal Dictionary of Sciences and Arts, Literature, and Practical Mechanics. By Thomas Curtis. 22 vols. 4to. with 1 additional vol. of maps. London, 1829.
14. The Encyclopædia Americana, a Popular Dictionary of Arts, Sciences, Literature, History, Politics, and Biography; on the basis of the 7th edition of the German *Conversations-Lexikon*. Edited by Francis Lieber, assisted by E. Wigglesworth and T. G. Bradford. 13 vols. 8vo. Philadelphia, 1829–'38. (A supplementary volume, edited by H. Vethake, was added in 1847.)
15. Lardner's Cabinet Cyclopædia, comprising a series of original works on History, Biography, Literature, the Sciences, Arts, and Manufactures. 132 vols. small 8vo. London, 1830–'46. (Among the numerous valuable treatises in this series are works of Herschel on astronomy, of Brewster on optics, Mackintosh's "History of England," Sismondi's "Italian Republics," Scott's "History of Scotland," and Thirlwall's "History of Greece.")
16. Partington's British Cyclopædia. 12 vols. 8vo. London, 1832.
17. The Penny Cyclopædia of the Society for the Diffusion of Useful Knowledge. Edited by George Long. 27 vols. small folio. London, 1833–'43, with 2 supplementary vols. in 1846–'51; 2d supplement, 1 vol. 1856.
18. The Popular Encyclopædia, or Conversations Lexicon; being a General Dictionary of Useful Knowledge, with Dissertations by Eminent Writers. 7 vols. royal 8vo. Glasgow, 1841.
19. Brande's Dictionary of Science, Literature, and Art. Royal 8vo. London, 1842; 2d ed., 1852–'53; an American ed., New York, 1843.
20. The National Cyclopædia of Useful Knowledge. 12 vols. small 8vo. London, 1847–'51; and Boston, 1853. (This is an abridgment of the "Penny Cyclopædia.")
21. The Iconographic Encyclopædia of Science, Literature, and Art. Translated from the German of J. G. Heck, with additions, and edited by Spencer F. Baird. 4 vols. royal 8vo. of text, and 2 vols. of plates. New York, 1851.
22. The English Cyclopædia, a New Dictionary of Universal Knowledge. Conducted by Charles Knight. To be completed in 20 vols. London, 1854 *et seq.* (This work is based upon the "Penny Cyclopædia," and is divided into the 4 departments of Geography, Natural History, Biography, and Arts and Sciences. The 2 first departments are

now completed in 4 vols. each, the 3d in 6 vols., and the remaining 6 vols. are announced to be issued in 1859–'60.)

Beside these larger works, a multitude of cyclopædias have been published, intended to impart information in special branches of knowlege, as Loudon's "Encyclopædias of Agriculture, Gardening, Architecture, Plants, Trees," &c.; Todd's "Cyclopædia of Anatomy and Physiology;" Nichol's "Cyclopædia of Physical Science;" Nicholson's "Encyclopædia of Architecture;" Chambers's "Cyclopædia of English Literature;" Duyckinck's "Cyclopædia of American Literature;" Homans's "Cyclopædia of Commerce;" and Allibone's "Critical Dictionary of English Literature."—On the continent, as well as in England, the "Cyclopædia" of Ephraim Chambers gave an impulse to the desire for such publications. A second edition of the French translation having been proposed, it was resolved, upon the suggestion of the abbé Gua de Malves, to divide the manuscript among several literati, in order to elaborate the respective articles on a more extensive scale, that they might be combined into a cyclopædia at once more original and more comprehensive than the English model and groundwork. The abbé having disagreed with the bookseller in the outset of this undertaking, Diderot and D'Alembert became its principal managers. Thus originated the great French *Encyclopédie*, which, at first intended to consist of 10, was enlarged to 28 folio volumes. Its title is *Encyclopédie ou dictionnaire raisonné des sciences, des arts, et des métiers, par une société de gens de lettres, mis en ordre et publié par M. Diderot, et quant à la partie mathématique par M. d'Alembert.* The first 7 vols. appeared in Paris (1751–'57); the remaining 10 vols. of text were published, according to the title page, at Neufchâtel (1765); and there were 11 additional vols. of plates. A supplement of 4 vols., with 1 additional vol. of plates, was issued at Amsterdam (1776–'77). A *Table analytique et raisonnée des matières* was added in 2 vols. (1780). The work, though several times interrupted by the government while in progress, was everywhere received with enthusiasm, and gave to the editors and principal collaborators a place in European history, and in the history of philosophy, under the name of the "Encyclopædists." Around Diderot and D'Alembert were grouped Voltaire, Rousseau, Turgot, Helvetius, Duclos, Condillac, Mably, Buffon, La Harpe, Marmontel, Raynal, Morellet, Grimm, Saint Lambert, and many others. Four new editions of it were rapidly issued, at Leghorn (33 vols., 1770), at Lucca (28 vols., 1771), at Geneva (39 vols., incorporating the supplements, 1777), and at Lausanne and Bern (36 vols., 1778). It was the basis also of the cyclopædia of Felice (Yverdun, 1770–'80, 48 vols., with 10 additional vols. of plates), among the collaborators of which were Euler, Lalande, and Haller. The *Discours préliminaire*, which is ranked among the *chefs d'œuvre* of the age, was written by D'Alembert. In it the author traces the genealogical order of the various branches of human knowledge, marks out the limits of each, its connection with the rest, and the characters which distinguish them in our minds. Bacon had made his celebrated partition of human learning into history, poetry, and philosophy, according to the powers of the mind respectively concerned in them, the memory, imagination, and reason. This psychological division is neither rigorous nor exact, and D'Alembert attempted to complete the classification by adding a distinction between the historic and the rational order of the sciences, between the order in which they are produced in society and that in which they logically stand related to each other. He therefore first reviewed the origin and progress of the arts and sciences, detailing the history of intellectual culture in Europe from the revival of learning, and finally raised the cyclopædic tree, following in general the classification of Bacon, and developing all the branches of learning according to their metaphysical dependences. The style of this discourse is severe and simple, adhering closely to the language proper to philosophy, yet rendering clear and palpable the most abstract ideas. The work itself exerted an immense influence in hastening the greatest political revolution of modern times. It was designed at once to reveal to the human mind the extent of its power by unfolding the picture of its riches, and to emancipate human thought by treating freely every science and doctrine; and it was conceived in a spirit indifferent, if not antagonistic, to the institutions, usages, and faith of the time. It is the most complete expression of the philosophical, critical, irreligious, and reformatory tendencies of the 18th century. Its generally polished and correct style, and its blending of philosophy, elegance, and gayety, made it fashionable in courtly society, and contributed much to its authority and influence. To counteract the disorganizing tendencies of the *Encyclopédie*, and to apply a more methodical system, was the design of the projectors of the *Encyclopédie méthodique*, the most elaborate work of the kind extant in France, published by Panckoucke and Agasse (201 vols., including 47 vols. of plates, Paris, 1781–1832). Its method consists in assigning to each science a special alphabetical dictionary, and the whole book is therefore a collection of 48 distinct cyclopædias or dictionaries of science, literature, and art, with dissertations interspersed throughout. Among the editors were Quatremère de Quincy for architecture, Bergier for theology, Mongez for antiquities, Ginguené for music, De Lamarck for natural history, and Vicq d'Azyr, Cassini, Latreille, Tessier, Naigeon, Condorcet, and Lacretelle for other departments. A Spanish translation of it (Madrid, 1780–1806, vols. i.–xi.) was commenced, but not completed. During the period which has elapsed since the commencement of this work science has made astonishing progress, and consequently several of the earlier parts are now of comparatively little value. The following are the most

important of recent French encyclopædias: 1. The *Encyclopédie moderne: Dictionnaire abrégé des sciences, des lettres, des arts, de l'industrie, de l'agriculture, et du commerce;* conducted by M. Courtin (26 vols. 8vo., Paris, 1823–'32; 2d ed. 1843; 3d ed., completely revised, under the direction of M. Léon Renier, 27 vols., with 3 additional vols. of plates, 1853–'55). A supplement to this work has reached the 7th volume, and the letter L (1859). 2. *Dictionnaire de la conversation et de la lecture*, directed by M. W. Duckett (52 vols., Paris, 1832–'39; 2d ed., revised and enlarged, 16 large 8vo. vols., 1853–'58). This cyclopædia is very unequally executed, but many of its articles are unusually complete and entertaining. 3. The *Encyclopédie des gens du monde: Répertoire universel des sciences, des lettres, et des arts; par une société de savans, de littérateurs, et d'artistes* (44 vols. 8vo., Paris, 1833–'44). 4. The *Encyclopédie du XIX siècle*, a Roman Catholic work, published by M. Saint Priest (28 vols., Paris, 1839–'52). 5. *Encyclopédie catholique: Répertoire universel et raisonné des sciences, des lettres, des arts, et des métiers, avec la biographie des hommes célèbres;* directed by the abbé Glaire and viscount Walsh (18 vols. 4to., Paris, 1840–'48; 3 vols of a supplement have already been added, 1859). 6. The *Encyclopédie nouvelle, ou dictionnaire philosophique, scientifique, littéraire, et industriel*, edited by P. Leroux and J. Reynaud (8 vols., Paris, 1834 *et seq.*). This work contains many remarkable articles, and is less a dictionary of general knowledge than a series of dissertations on various subjects. Its editors were distinguished philosophers of the Saint Simonian school, the collaborators few in number, and the elaborate articles present throughout a unity of view and doctrine. 7. The *Dictionnaire des sciences philosophiques, par une société de professeurs de philosophie*, directed by M. Franck (5 vols., Paris, 1844–'52). 8. The *Dictionnaire général de biographie, d'histoire, de géographie, des antiquités, et des institutions*, &c., by Dezobry and Bachelet (2 thick 8vo. vols., Paris, 1857). 9. The *Dictionnaire universel des sciences, des lettres, et des arts*, by M. Bouillet (1 vol. 8vo., Paris, 3d ed. 1857). 10. The *Dictionnaire universel d'histoire et de géographie*, by M. Bouillet (1 vol. 8vo., Paris, 14th ed. 1858). 11. The *Grand dictionnaire de géographie universelle*, by M. Bescherelle (4 vols. 4to., Paris, 1856–'57). The chief French cyclopædic periodicals, reviewing the whole field of knowledge, have been the *Revue encyclopédique* of Jullien (Paris, 1819–'33), and the *Bulletin des sciences* of Ferussac (Paris, 1823–'31).—Among the early German cyclopædias the most celebrated is the *Oekonomisch-Technologische Encyklopädie*, commenced at Berlin in 1773, by J. G. Krünitz, and continued successively by F. J. Flörke, H. G. Flörke, J. W. D. Korth, and C. D. Hoffmann. There have already (1859) been published 220 vols. 4to., and it is nearly concluded. Though originally limited to economy and technology, it has become almost a general cyclopædia. A new, unchanged edition of the first 97 volumes appeared at Berlin (1782–1814), and another edition (32 vols., Berlin, 1785–1812) includes 116 volumes of the original work. The *Deutsche Encyklopädie*, begun at Frankfort-on-the-Main, by H. M. G. Köster (1778), and continued by J. F. Roos to the 23d volume as far as the letter K (1804), remains unfinished. It excludes biography, geography, history, and ancient literature. The *Allgemeines Lexikon der Künste und Wissenschaften*, by J. T. Jablonski, appeared in Leipsic (1721; new ed. at Königsberg, 1748–'67, in 2 vols.). Theology, history, and geography were excluded from it. The *Grosses Vollständiges Universal-Lexikon aller Wissenschaften und Künste*, edited successively by Ludewig, Frankenstein, Longolius, and others, and commonly called Zedler's Lexicon, after the publisher (64 vols., Halle and Leipsic, 1732–'52; 4 supplementary vols. added, 1751–'54), is still useful on account of the citations, and of its carefully prepared genealogical articles. The most comprehensive German work of this character is the celebrated *Allgemeine Encyklopädie der Wissenschaften und Künste* of J. S. Ersch and J. G. Gruber, late professors at Halle (Leipsic, 1818 *et seq.*; not yet concluded). In 1831 the undertaking passed from the hands of Enoch Richter, who began it, to the Brockhaus firm, its present enterprising publishers. The work is divided into 3 sections, the 1st including A–G, the 2d H–N, and the 3d the remaining letters of the alphabet. The sections are prosecuted contemporaneously, the 1st since the death of Ersch being edited by Gruber and M. H. E. Meier; the 2d, by A. G. Hoffmann in Jena; and the 3d, by M. H. E. Meier in Halle. More than 125 large 4to. vols. have (1859) been issued. This cyclopædia is esteemed the most learned and thorough that has appeared in any literature. Biographies of the living are excluded from it. A new epoch in the literature of cyclopædias began with the publication of the *Conversations-Lexikon* (6 vols., Leipsic and Amsterdam, 1796–1810); a work of unequalled popularity, which has passed through 10 successive editions at home, and been translated into numerous languages abroad. The idea of the work originated with Dr. Löbel; it was, however, completed under the inspection of F. A. Brockhaus, who conducted the second edition (10 vols. 1812–'19). It was originally designed for the use of persons who might desire to take a part in the conversation and society of well-informed circles. This distinctive feature of the work has, however, been to a certain degree changed by numerous improvements in successive editions, so that its present title, *Allgemeine Deutsche Real-Encyklopädie für die gebildeten Stände* (*Conversations-Lexikon*), conveys a clearer idea of its general character. The latest edition was published at Leipsic (15 vols. in 16, 1851–'55). Several important cyclopædic works have been issued by Brockhaus, in connection with the *Conversa-*

tions-Lexikon, as the *Conversations-Lexikon der neuesten Zeit und Literatur* (4 vols., Leipsic, 1832–'34); the *Conversations-Lexikon der Gegenwart* (4 vols., 1838–'41); the *Gegenwart*, a periodical, in which the alphabetical order was abandoned, but which consisted of essays giving a cyclopædic exhibition of the present time (12 vols., 1848–'56); and *Unsere Zeit*, a monthly periodical of a similar character now in progress (1857 *et seq.*). The *Universal-Lexikon der Vergangenheit und Gegenwart* of Pierer (26 vols., Altenburg, 1824–'36; 6 supplementary vols., 1840–'47; 2d ed., 34 vols., 1840–'46; 3d ed., 17 vols., 1849–'53; supplement of 6 vols. added, 1851–'54, and of 2 vols., 1855; 4th ed., Altenburg and New York, 1857 *et seq.*). This cyclopædia is admirable for its universality and for the brevity and completeness of its statements. The other principal German cyclopædias are: *Encyklopädisches Sachwörterbuch* (21 vols., Zeitz, 1792–1806; 2d ed., 3 vols., 1822–'23), which excludes biographies and natural history; the *Conversations-Lexikon für alle Stände* (8 vols., Leipsic and Halberstadt, 1823–'28), often called from its publisher the "Brüggeman Cyclopædia;" the *Damen-Conversations-Lexikon* (10 vols., Leipsic, 1834–'38; 2d unchanged ed., Adorf, 1846); Meyer's *Conversations-Lexikon* (50 vols., Hildburghausen, 1839–'55), which is more comprehensive than any other Conversations-Lexicon; a new *Conversations-Lexikon* begun by Meyer (Hildburghausen, 1856 *et seq.*); the *Conversations-Lexikon für alle Stände*, published by Wigand (15 vols., Leipsic, 1846–'52); the *Allgemeine Real-Encyklopädie, oder Conversations-Lexikon für das Katholische Deutschland*, by W. Binder and others (12 vols., Ratisbon, 1846–'51); and the *Real-Encyklopädie für Protestantische Theologie und Kirche*, by Dr. Herzog (Stuttgart and Hamburg, 1854 *et seq.*); the last work reached in 1858 the letter M and the 9th vol.; an English condensed translation of it is in progress by J. H. A. Bomberger (Philadelphia, 1858 *et seq.*, designed to be in 3 vols.).—The most important Italian cyclopædias are the *Nuovo dizionario scientifico e curioso sacro-profano*, by Pivati (12 vols. folio, 1746–'51); and the *Enciclopedia Italiana* (Venice, 1854 *et seq.*). Cyclopædias exist also in most other European languages, as, in Danish, the *Almennyttigt Dansk Konversations-Lexicon*, by P. Larsen (Copenhagen, 1849 *et seq.*); in Swedish, the *Svenskt Konversations-Lexicon* (Stockholm, 1845 *et seq.*); and in Spanish, the *Pan-Lexicon*, by Juan Peñalver (Madrid, 1842), the *Biblioteca universal de instruccion* (Barcelona, 1842 *et seq.*), and the *Enciclopedia Española del siglo XIX.* (Madrid, 1842 *et seq.*).—The oriental nations have general and special, systematic and alphabetic cyclopædias. The most complete of them is in Arabic, systematically arranged, and entitled *Miftah es-seâdet ve missbah es-siyâdet fi mevzuat elooloom* (the key of happiness and the guiding beacon in the objects of the sciences), by Mola Ahmed ben Mustapha, commonly called Tash Köprisade. It was translated into Turkish by the son of the author, Kemal eddin Mohammed (died in the year of the Hegira 1032, A. D. 1622). It divides the sciences into 7 classes, rhetoric, eloquence, dialectics, theoretical philosophy, practical philosophy, theoretical positive science, and practical positive science. Tash Köpri-sade reckoned in all 307 sciences, which his son extended in the Turkish version to 500. A general alphabetically arranged cyclopædia was prepared by Hadji Khalfa, whose proper name was Mustapha ebn Abdallah Kalib Tshlebi (died A. D. 1657). This voluminous writer on the bibliography, geography, and history of the Moslems collected many separate and rare treatises into one body under the title of *Keshf es soonoon an Esmail Kootoob velfoonoon* (the knowledge of books and sciences). In his introduction he treated of the nature, object, and classification of the sciences; of the history and literature of the sciences in oriental countries; of several special questions concerning the history of learning; and of the Arabic language and literature. The whole of this introduction is translated in Von Hammer's *Encyklopädische Uebersicht der Wissenschaften des Orients* (Leipsic, 1804). These two immense collections were preceded by several cyclopædias more or less complete. The first who among the Arabians made a cyclopædic scheme of the sciences was the celebrated physician Abu Ali ebn Abdallah ebn Sina, known among Europeans by the name of Avicenna (died A. D. 1037). Of his treatise on the nature of the sciences and the method of teaching we are able to judge only from the high commendations of Tash Köpri-sade, the greatest oriental cyclopædist, who acknowledges obligations to no other of his predecessors. The oldest proper cyclopædia among the Arabians was the *Hadaikol-envar fi hakaik il-esrar* (garden flowers or true mysteries), by Takhr eddin Mohammed ben Omar Er-rasi (died A. D. 1209), which embraces 60 sciences. About a century later appeared the cyclopædia *Miftahol-ooloom* (key of sciences), by Serad-sheddin ebn Yakub Yussuf ben Ebi Mohammed ben Ali es-Sakaki (died A. D. 1280). This work enjoyed an unrivalled reputation for a century and a half, and more than 100 commentaries were written on it, and even a larger number of epitomes of it were made. Among the latter was an excellent elaboration of the rhetorical division by Shems eddin Mohammed, celebrated as the "preacher of Damascus" (died A. D. 1338). Under Mohammed II., the conqueror of Constantinople, several cyclopædias of large compass were produced. One of these was a learned work on 14 sciences, by an Egyptian named Dshelaleddin Abderrahman ben Ebibekr Essoyuti (died A. D. 1505), parts of which were reduced to verse by several scholars. A great cyclopædia in the Persian language is the *Nefais olfoonoom fi arais il ooyoon* (treasures of knowledge to adorn the eyes), which embraces 120 sciences. It is in 2 parts; the 1st

treating of the pre-Islamitic sciences in 5 books, the 2d of the Islamitic sciences in 9 books. The *Elfevaid elkhakanïe el-Ahmed khanie* (useful results, &c.), by Mohammed Emin ben Sadr esh-Shirvani, is a famous cyclopædia, prepared for the sultan Ahmet I. It treats of 53 sciences in 5 parts, which, like the parts of an army, are entitled: the van (sciences and their order), the right wing (philological sciences), the left wing (philosophical sciences), the rear (the ethics of monarchs), and the centre (the sciences of law). The Chinese and Japanese also have great cyclopædias. Almost the whole contemporary learning is contained in the *Ku-kin-ssé-wen-lui-tsiu* (ancient-modern 4 collections), by Chu-ho-fu (1246). Similar Chinese works in the 17th century attained to immense magnitude. The *San-tsai-tu*, in 130 vols., treating of the 3 great powers, heaven, earth, and man, was published in Japanese near the beginning of the present century, and there is a copy of it, both in Japanese and Chinese, in the royal library of Paris.

CYCLOPISM (Gr. κυκλος, a circle, and ωψ, eye), a form of monstrosity, in which a single eye is developed in the middle of the forehead. Such monsters belong to the family of cyclocephalians of Isidore Geoffroy St. Hilaire, in which, with a more or less complete atrophy of the nasal apparatus, the organs of vision are imperfectly formed, with a tendency to approach the median line, and sometimes with a complete fusion of the two; the jaws also present more or less deformity, but the ears are generally normal. These monsters have attracted special attention from their resemblance to the fabulous Cyclops, particularly Polyphemus, rendered celebrated by the verses of Homer, Virgil, and Ovid; no doubt, these poetic creations were founded on actual observation of some of these not uncommon deformities. Some of the divisions of this family have two eyes, placed either in a single or a double orbit; in the latter case the nose is atrophied, with or without a kind of trunk above the eyes; these cannot strictly be called cases of cyclopism, though belonging to the same order of deformities, and are comparatively rare. The most common form is the *rhinocephalus*, in which the nose is atrophied, being represented only by a proboscis on the lower part of the forehead, and the eyes either close together or fused into one in a single orbit; in extreme cases there is only a single cavity without eyes. The single eye of the true cyclops is in the median line of the forehead, symmetrical, with a central pupil and an upper lid; it is generally larger than a common eye, and more elliptical in shape, with a single cornea and lens; this modification may be traced in the series of such anomalies from two contiguous eyes to a single apparently normal organ. The artistic representations of Polyphemus have always been erroneous, in that they have made his single eye either a right or a left one; every organ on the median line must be symmetrical, but neither a right nor a left eye is so; the cyclopean eye, however, is symmetrical, and formed by the union of parts corresponding to two eyes, the outer or the inner halves, either of which would make a symmetrical organ. The accessory organs, as the lids, the lachrymal apparatus, vessels, nerves, and muscles, are double or single according to the condition of the globe of the eye; the bones forming the orbit are modified in a similar manner, the frontal being narrowed, the orbital processes of the upper maxillary joined together and very small, and the malar bones almost meeting on the median line; according to Meckel and Geoffroy St. Hilaire, the anterior portions of the cerebral hemispheres are united, with a fusion of the lateral ventricles, diminution of the corpus callosum, a less number of convolutions, small size of the entire organ, and increase of serous fluid. Of course the eyes could not come together without atrophy of the nose, which is displaced upward, forming the proboscis seen in such cases on the forehead; and all the component parts of this organ show the same tendency to fusion on the median line; the same condition of partial fusion is found in the upper and in the lower jaw, the intermaxillary often disappearing, or a median incisor representing the union of two teeth. This form of monstrosity occurs in man, the dog, cat, rabbit, calf, sheep, horse, and birds, but especially in the pig, which furnishes more than half of the cases of this, as of most other anomalous conditions. In the true *cyclocephalus* the proboscis is wanting, indicating a still greater degree of monstrosity; the genus *stomocephalus* differs from *rhinocephalus* in the deformity of the lower jaw or the entire absence of the opening of the mouth; these two forms are comparatively rare. Certain very small crustaceans have the eyes quite close together, and even confounded in a single mass, and are hence called cyclops. These monsters, both human and animal, are generally born living and in good condition, and are most frequently females; they perish soon, probably from the inability of their imperfectly developed brain to answer the requirements of extra-uterine life. Many authors explain this form of monstrosity by an arrest of development, maintaining that every eye is cyclopean at a certain stage of growth, being developed from a central cerebral vesicle; but, from the fact of similar conditions occurring in the ears, the teeth, the legs, the arms, all of which may exist singly and symmetrical on the median line, Prof. J. Wyman ("Proceedings of the Boston Society of Natural History," vol. vi. p. 380) is of opinion that a single vesicle is primarily formed on the median line in such cases, instead of one on each side as in the normal state.—See *Histoire des anomalies de l'organisation*, by Isidore Geoffroy St. Hilaire, vol. ii. pp. 375–420.

CYCLOPS (Gr. κυκλωψ; κυκλος, a circle, and ωψ, an eye), in the Grecian mythology, a race of giants, with but one circular eye in the middle of the forehead, of whom there are various traditions. Those of the Odyssey are a gross race

of cannibal shepherds in Sicily, whose chief is Polyphemus. The Cyclops of Hesiod are sons of Uranus and Gæa, 3 in number, called Brontes, Steropes, and Arges, who were hurled into Tartarus by their father, released and reimprisoned by Saturn, and finally freed by Jupiter. For the latter, they made the thunderbolts, his invincible artillery; for Pluto, his helmet; for Neptune, his trident. They were killed by Apollo, in revenge for the death of his son Æsculapius, who was destroyed by Jupiter with the thunderbolts they had furnished him. A later tradition makes them the assistants of Vulcan, forging metallic armor and ornaments for gods and heroes in the volcanoes of Lemnos and Lipari, and under Mt. Etna. According to K. O. Müller, the Cyclops of Hesiod denote the transient disturbances of the order of nature by storms; Grote finds this opinion unsupported by the "Theogony" of the poet.—The name of Cyclopean walls has been given to those uncemented walls of unhewn stones, of which remains abound in several regions of Greece, and in Etruria, and which were probably erected by Pelasgians. Their huge size and uncouth form were the reason of their being attributed to the fabulous giants.—In English the word Cyclops is both singular and plural.

CYDNUS, a river of Cilicia, rising in the Taurus, and flowing through Tarsus into the Mediterranean sea a little below that city, was celebrated for the clearness and coldness of its waters, which in the opinion of the ancient physicians possessed medicinal virtues. The mouth of the Cydnus is now choked with sand and other alluvial deposits.

CYDONIA, an ancient city of Crete, rival and enemy of Cnossus and Gortyna, stood on the N. W. coast of the island, and derived its name from the Cydones, an aboriginal race who founded it. Afterward a colony of Zacynthians settled there. Next came the Samians in the 6th century, and ultimately appeared the Æginetans, who seized on the city. It was famous for quinces.

CYGNUS, a northern constellation, made memorable by containing the first star whose distance from the sun was approximately determined.

CYLINDER, a solid figure enclosed by parallel straight lines passing through every point of a curve. If the curve be a circle, and the lines at right angles to it, the cylinder is called a right cylinder.

CYMA, or CYMATIUM (Gr. κυμα, a wave), in architecture, the name of a moulding of a wave-like form, of which there are two kinds, the *cyma recta*, hollow in its upper part and swelling below, and the *cyma reversa*, which swells above and is hollow below.

CYMBALS (Gr. κυμβαλον, from κυμβος, hollow), brass musical instruments of percussion, consisting of 2 hollowed plates, circular in shape, and from 6 to 8 inches in diameter, which are attached to the hands by leather bands, and played by being struck together. The instrument is of great antiquity, having been used in the worship of Cybele, Bacchus, Juno, and all the earlier deities of the Grecian and Roman mythology, and probably by the Jews and most of the eastern nations. It was usually made in the form of 2 half globes.

CYME, the largest of the Æolian cities of Asia Minor, with a good harbor. It was founded by Locrians, and was the mother city of Cumæ in Campania.

CYNÆGIRUS, an Athenian warrior, who greatly distinguished himself at the battle of Marathon, 490 B. C. He was the son of Euphorion, and brother of the poet Æschylus. When the vanquished Persians were endeavoring to escape from the fatal field to their ships, he seized one of their triremes with his right hand, and when that was severed he grasped the vessel with his left; and when the left too was gone, he held on to the hostile galley with his teeth.

CYNICS, a school of Greek philosophers, founded by Antisthenes, a pupil of Socrates, in Athens, in the gymnasium Cynosarges, about 380 B. C. The most renowned among them were Diogenes, Crates of Thebes, his wife Hipparchia, and Menippus. They taught that all speculative philosophy led to no real knowledge of truth, but only to sophistry and the destruction of virtue and human society, and that the only task of philosophy was to show how men might best live morally and peaceably. In this they harmonized with the Stoics, but they differed from them in defining virtue to be the highest possible simplicity in living, and independence of external or sensual goods, and in carrying this so far that they despised decency, cleanliness, civilization, and labor. Hence their name became a by-word, and was sneeringly derived from κυων (dog); they were called a doggish set, and the name Cynic is still applied to men who disregard the proprieties of life under the pretence of independence of character.

CYNOSCEPHALÆ (Gr. κυων, a dog, κεφαλαι, heads), the name of a range of mountains in Thessaly, famous in history for two battles which were fought on it. The first was in 364 B. C., when the Thebans, though victorious over the Pheræans, lost their general Pelopidas. The other was in 197 B. C., when the Roman consul Flaminius defeated and took prisoner Philip II., king of Macedon.

CYNOSURE (Gr. κυων, a dog, ουρα, a tail), the name formerly given to the constellation Ursa Minor. This constellation contains the pole star, and was on this account an object of much attention to mariners and travellers.

CYNURIA, in ancient times, a district of the Peloponnesus, inhabited by a rude tribe of Ionians. They were a plundering race, and when attacked would retire to their mountain fastnesses. They were, however, subdued by the Argives at an early period, and about the middle of the 6th century B. C. their country passed into the possession of Sparta. The city of Thyrea (now Astro), with the country around, formed part of this ancient district.

CYPRÆA, the name of a genus of marine shells of the class *gasteropoda*. The shells are of oval or oblong form, more or less rounded or cylindrical, with a small and imbedded spire. The longitudinal aperture is nearly straight, and toothed or plaited on each side, with a channel or groove at each end. The genus is remarkable for the differences between the shells of the young and adult individuals, the outer lip in the early stages of growth being thin and the aperture wide. By the gradual inflection and thickening of this lip the aperture becomes narrower, and the shell assumes the nearly symmetrical form of the adult individual. About 150 living species are known, and 78 fossil. The genus first appeared in the chalk formation. (See Cowry.)

CYPRESS (*cupressus*, Linn.), the name of a tree remarkable for the durability of its timber, and belonging to the coniferæ; distinct from the pines and firs, by its leaves being reduced to mere scales, and by its cones consisting of a few woody bracts, each of which bears several small angular seeds. The common evergreen or upright cypress (*C. sempervirens*, Willd.) is a tapering, cone-like tree, with upright branches growing close to the trunk, resembling in general appearance the Lombardy poplar, and attaining in its native condition an altitude of 50 or 60 feet, though sometimes it is found much higher. According to Duhamel, a substance resembling gum tragacanth exudes in small particles from the bark of the young trees, and is collected by the bees for some purpose in constructing their combs. It is this species which, found wild in the islands of the archipelago, particularly Candia, and in Cyprus, Greece, Turkey, Persia, and Asia Minor, has been for a long time transferred to gardens for the sake of its deep evergreen branches and leaves, and for the gloomy air it imparts to the localities which it occupies. Among the Turks it is much esteemed for planting in cemeteries, and is used to such extent that these grounds resemble forests of cypresses. It is the kind mentioned in the Scriptures, and was famous among the ancients. Instances are related of doors and posts made of its wood, which had lasted 1,100 years. The odor of the cypress was considered so balsamic, that the eastern physicians used to send their patients troubled with lung complaints to the isle of Crete for a residence. The most renowned cypress tree is that of Somma, in Lombardy, said to have been planted the year of the birth of Jesus Christ, but records in existence declare it to have been a considerable tree 42 years B. C. When measured a few years ago, it was found to be 121 feet high, and 23 feet in circumference one foot from the ground. Some cypress trees planted by Michel Angelo in the garden of the Carthusian convent, situated on the site of the baths of Diocletian at Rome, are regarded with interest. The largest of these, when visited by M. Simond in 1817, measured about 13 feet in circumference. There are also some fine specimens in France and in England, of great size and considerable age. Any garden soil suits the cypress, but a deep and rather dry and sheltered soil suits it best. It can be raised from the seeds, sown in shallow pans, and the young plants on reaching 3 or 4 inches in height need to be potted off and kept for a few years with some care to render them fit for transplanting into open grounds. Cuttings taken from the younger branches, if planted during the autumn, will grow and succeed. Little training is necessary, on account of its natural tendency to grow upright. We are not aware of the cultivation of the cypress in this country, but it would doubtless succeed in any latitude similar to that of England, or warmer. The *C. horizontalis* (Duhamel) has spreading branches, which, when loaded, as they usually are, with large round cones, render the tree a beautiful object. It is considered to be only a fine variety of the common cypress. The Portuguese cypress (*C. Lusitanica*, Tournefort), a native of Goa, in the East Indies, has flexuous, spreading branches, and imbricated, acute, keeled, glaucous, adpressed leaves in 4 rows. It has been long naturalized in Portugal, where it acquires a large size. The weeping cypress (*C. pendula*, Thunberg) is a native of China; it has a large, expanded head, and dichotomous branches, which are much divided; its leaves are imbricated in 4 rows, are rather stem-clasping and triquetrous, keeled, and adpressed. According to Loudon, some uncertainty is attached to this species. Mention is made of it in Lambert's "Pines," and in Staunton's "Embassy," and it is the *fimoro* of Kämpfer. In the United States, the cypress is represented in the white cedar. (See Cedar.)—The deciduous cypress (*taxodium distichum*, Richard.) is a stately tree of the pine family, much admired for its foliage of a most delicate light green, which falls in the autumn after turning to a bright tawny color. Its leaves are linear and spreading, awl-shaped, and imbricated on the branches which produce the flowers; its seed vessels or strobiles are small, subglobose, and formed of angular woody scales. This lofty tree is a native of the middle and southern states of North America, extending from Delaware to the extreme south. Its trunk is very thick, often from 25 to 40 feet in circumference at the base, and attaining to 120 feet in height. The branchlets are very slender, elegantly pinnate; the leaves pectinate and distichous, spreading horizontally from being twisted at the base, linear, mucronulate, flat, one-nerved, glabrous on both sides, light green, margins acute, exterior somewhat convex, ½ an inch or more in length, and about a line broad. The tree, as it grows old, according to Michaux, has a spreading, broad head. It assumes, however, a great variety of forms, when raised artificially from the seeds. Loudon, in his *Arboretum Britannicum*, enumerates 4 principal forms, viz.: 1, the species having the branches horizontal, or somewhat inclined upward; 2, with the branches pendulous; 3, with the branches horizontal,

and the young shoots of the year pendulous, the leaves being twisted and compressed round them in the early part of the season, but fully expanded, like those of the species, toward the autumn; 4, with the leaves on the young shoots tortuous, and the branches pendulous. It is in the southern states, particularly in Florida, that the deciduous cypress attains its largest size, when it grows on the deep, miry soil of the swamps. The base of its trunk is usually hollow for ¼ of its bulk, and its surface is longitudinally furrowed with deep tortuous channels. The roots of the large trees, particularly in situations exposed to inundations, have strange-looking conical protuberances, called cypress knees, which rise above the soil, about 2 feet in height, and sometimes from 4 to 5 feet in thickness; these are hollow, smooth on the surface, and covered with a reddish bark like the roots, which they resemble also in the softness of the wood. The wood of the trunk is esteemed for timber, and is applied to various uses. Under cultivation at the north, this is one of the most beautiful and ornamental of trees. One in the Bartram garden, says Dr. Darlington in his *Flora Cestrica*, is the noblest specimen in Pennsylvania, and was planted by its venerable founder more than a century ago. Some good specimens are also to be seen in the gardens of Salem, Mass., which seem to thrive, and prove themselves capable of resisting the climate of the north. In one instance, the curious knobs from the root above described have begun to appear above the soil.

CYPRIAN, Thascius Cæcilius, a saint, bishop, and martyr of the early church, born at Carthage about the beginning of the 3d century, died Sept. 14, 258. His parentage was noble, his father being one of the senators of Carthage, and we infer from his letters that he was carefully trained, and that his morals and acquirements were those of most heathen youths in his station. His authentic history begins with the year 246, when he was baptized. At this time he was a man of mature years, of great popularity, of large fortune, lived in splendid style, and when he walked in the streets was followed by a crowd of admiring clients. His profession seems to have been that of a teacher of law. The immediate instrument of Cyprian's conversion was an old priest of Carthage, by name Cæcilius. Against the remonstrances of his pagan friends, who could not understand how a wise man should be beguiled by those foolish Christian fables, he openly declared his renunciation of idolatry, sold his gods and gave the price to the poor, went into retirement, and devoted himself to the study of the Scriptures and the Fathers. The first fruit of his conversion was his letter to Donatus, on the "Contempt of the World," in which he somewhat turgidly contrasts the pleasures of sense and of indulgence with the pleasures of inward musing and the joy of spiritual renewal, and describes in exuberant rhetoric the effect of regeneration. This letter was speedily followed by a treatise on the "Vanity of Idols," in which the crimes of the heathen gods are exposed and their demonic rather than divine nature illustrated. These books, added to the high social position of their author, led to his ordination as priest; and hardly had this occurred, when on the death of the bishop, Donatus, he was chosen by the prompt and enthusiastic voices of the Christians of Carthage, and the neighboring bishops, to the vacant episcopal chair. Five priests only dissented from the choice, objecting that he had not fulfilled a sufficient novitiate to test his fidelity. According to Pontius, his biographer, he submitted with great reluctance to this choice, and attempted to escape by a window, when they besieged his house, pressing his acceptance. The first years of his episcopal life, though not free from annoyances caused by the discontented priests, whom all his attentions could not quite pacify, were yet comparatively quiet. Affairs of discipline called for his decision, and he was ready for every call. A priest had been appointed by one of his friends, contrary to the canon of the church, to be executor of his will and guardian of his children; Cyprian not only deprived of his office this offending priest, who had dared thus to join secular to spiritual duty, but visited with posthumous excommunication the man who had made such a will. A converted actor continued to teach his art, pleading that his livelihood depended upon it; the bishop would not allow that a man might teach others what it was unlawful for himself to continue, and refused him the communion. An aged bishop complained that his deacons insulted him, and Cyprian must write and tell him how to treat them. The dress and bearing of virgins, which so much exercised Tertullian's mind, called for a new word from his admirer, and in his treatise on the "Habit" of this class, Cyprian inveighs against show and immodesty with hardly less severity than the ascetic Montanist. He magnified his office also by assuming a general supervision in the surrounding churches, and sustained by his care of ecclesiastical affairs throughout the province the recognized rank of a Carthaginian primate. In the year 250 the Decian persecution broke out, and raged at Carthage with especial fury. From motives of prudence, Cyprian preferred to withdraw to a place of safety, rather than expose himself to the hatred which was peculiarly bitter against him. Some seemed to see cowardice in this course, and it was made a reproach by his enemies; but his subsequent conduct in time of pestilence, and in the persecution of Valerian, proved that he was not afraid to meet the gravest dangers. From his retirement he still continued to direct the affairs of the church, to restrain abuses, to encourage the timid, and to console those whose friends had been martyred. In the extremity of peril, great numbers were driven to renounce their faith; others hypocritically pretended to adore the idols; and still others purchased certificates that they had re-

nounced the Christian faith, and so saved themselves from arrest, while they were spared the shame of a public apostasy. This class, called *libellatici*, were eager, when the persecution subsided, to regain their places as true believers; and some of them, in token of their fitness, brought recommendations which they had procured from those who had died martyrs. These *libelli pacis* seemed to release their holders from the necessity of preliminary penance, and to atone for the evasion by which life and safety had been bought. Cyprian would not allow this claim. He required as full an atonement from these compromisers as from other apostates, nor would he admit the authority of the martyrs in such a case, procured as it was by improper soliciting. He not only rejected these certificates, but he rebuked those who courted martyrdom for lending themselves to such schemes. This apparent irreverence and harshness aided the enemies who had before opposed him, and Novatus, one of the 5 dissenting priests, with Felicissimus, an influential demagogue, organized a separate church in the neighborhood, to which they admitted the apostates without any question. Cyprian declared them and their party schismatics, and excommunicated them. But Novatus was not yet ready to yield; he fled to Rome, where he intrigued against the bishop whom he hated, and also organized a party against the new Roman bishop Cornelius. Cyprian became by his pen a party in this Roman controversy, and his influence tended to secure Cornelius in his position, and to defeat the schemes of their mutual enemies. The controversy is significant in Cyprian's life, as it produced his book on the "Unity of the Church," in which he develops his theory concerning discipline and penance, schisms and heresies. The work is characteristic of his legal mind and his firm temper. Cyprian argues that it is not only an injury to the church, but an injury to the *lapsi* themselves, to readmit them without due penance. The persecution of Decius was not of long duration, and in the next year (251) Cyprian quietly returned to Carthage. His first care was to summon a council of the neighboring bishops to decide upon the affair of the penitent apostates, and to condemn the schism. The results of this council, which corresponded to Cyprian's wishes, were sent to the principal churches of the province, and to the Roman bishop. The condemnation did not at once silence the schismatics; they chose another bishop, Fortunatus by name, and succeeded in winning from Cornelius a partial assent to their conduct, and a remonstrance against the course of Cyprian. Sharp letters passed between Cornelius and his friend, in which Cyprian stoutly defends his episcopal right, insisting that a case once so clearly decided needs no revision, that it is enough that the schismatics have been judged guilty by their peers. A second council had already confirmed what the first had decided, and there seemed no ground for the charge that the action of the orthodox party had been hasty or arbitrary. Under the lead of Cyprian, the African bishops became the foes of schism abroad as much as of schism at home. Scarcely had the persecution subsided, when the plague, which had already appeared in Africa, broke out with renewed violence. In one of his letters Cyprian gives a graphic account of the symptoms and progress of this distemper. Hardly a house in Carthage was left by it unvisited. The panic was almost universal. The natural affections of families were forgotten; parents forsook their children, and men turned their fainting friends into the streets to die. Robbers took advantage of the distress to ply their trade, plundered the corpses on the highways, and ravaged the deserted houses. In this crisis Cyprian took control. From house to house he went with his followers, soliciting alms for the destitute, counselling the timid to stay and not flee, and gathering all who would dare such a service to tend the sick and bury the dead. He made no distinctions, but forgetting that only a few months before the pagans of Carthage had cried, "Cyprian to the lions," distributed his succor impartially to heathen and Christian. In this self-devotion he was joined by numbers of his brethren, and hundreds of Christian lives were lost in the work of mercy. But the pagans affirmed that the gods had sent that chastisement to punish the denial of their worship by these blasphemers; the crimes of the Christians were the cause of the wide disease. And when the Christian villages of Numidia were ravaged by the barbarians from the mountains, no Roman forces went to their rescue; it was reserved for the bishop to rescue them by the gifts of the Christians. Impoverished as the faithful of Carthage already were by their sacrifices in the season of pestilence, they answered promptly to Cyprian's call, and he could transmit to the provinces, as ransom for their imprisoned brethren, 100,000 sesterces, a sum amounting to near $4,000 of our money. This act of charity only gave occasion for scandal to the pagans, and Cyprian had to conduct a vexatious controversy with the magistrate Demetrian, in which he maintained that the disasters of plague and battle had come upon them in consequence, not of the Christian faith, but of heathen iniquities. Questions of dispute were constantly presented to Cyprian, and repeated councils were called by him to settle points of discipline and faith. But the most serious question, and one which brought him into conflict with the Roman bishop, was that of rebaptizing heretics. Cyprian, in this matter, favored a strict construction of the canon, and holding that no baptism except that of the church was valid, maintained that heretics must be treated as if they had never received the rite. The opposite party maintained that the conversion of heretics consecrated the original rite, even if it were not in the first instance canonically administered, and that repetition was superfluous. Cyprian's opinion had long prevailed in the church at Carthage, and had been confirmed by a synod held by one

of his predecessors; but to satisfy some doubters, he summoned a new synod of 32 bishops, who ratified the existing custom. Their verdict and the letters of Cyprian not quieting the objectors, a still more numerous synod of 87 bishops reiterated the sentence. The bishop of Rome, nevertheless, did not admit the justice of their conclusion. He wrote to Cyprian that it was of no moment to ask who administered the baptism, provided that it was received in good faith, and the proper form was observed. He renounced fellowship with Cyprian unless the church of Carthage should reconsider its opinion. Cyprian summoned, at the close of 256, a 3d synod, in which were deputies from Mauritania and Numidia, as well as from the province of Carthage, and procured an authoritative declaration of his opinion concerning the baptism of heretics as the orthodox doctrine of the church of Africa. This course seemed to make that church heretical, and the Roman bishop declined to receive the African messengers, and forbade his people to commune with them.—The martyrdom of Cyprian is one of the most touching traditions of the African church. For a few years the church had enjoyed rest from pagan persecutions; but in the year 257 an edict of Valerian authorized prefects and proconsuls to bring Christians to trial, and punish them if they confessed their faith. The proconsul of Africa was not slow to use this permission. Summoning Cyprian, he bade him renounce his false worship and sacrifice to the gods. "I am a Christian and a bishop," said Cyprian; "I know no God but the one true God, who created heaven and earth, and all therein. I serve him, and all Christians serve him, and pray to him for the emperor." No information concerning the residence of his priests could be got from the sturdy prelate. Banished for his contumacy to Curubis, a small city on the sea-coast, about 50 miles from Carthage, he lived for nearly a year in retirement, visited by his friends, and supplied with every convenience. His time was spent in sacred studies, and in writing letters of encouragement to his afflicted brethren. Recalled by the successor of this proconsul, Cyprian assumed the active duties of his station; but a new edict, more severe, led to a second arrest. Cyprian had been just before notified by the bishop of Rome of the impending fate, and already that bishop was a martyr. The proconsul Maximus sent a guard to conduct him to Utica, where the court was at that time sojourning, but the bishop preferred to suffer among his own people, and secreted himself for a time from the guard. When the proconsul returned, Cyprian walked abroad again, and was ready for the soldiers when they came to take him. The delay of a day in the trial caused the rumor of his arrest to be spread through Carthage, and the excitement and grief were unbounded. His prison was closely guarded by night for fear of rescue, and on the morrow he was conducted to the prætorium. It was noticed as a providential chance that the seat in which he sat was covered with a linen cloth, as if to symbolize his episcopal dignity. A few edifying words passed between him and the proconsul, the expected sentence was read, and, as a ringleader of the impious sect to whom so many crimes were charged, Thascius Cyprian was condemned to be beheaded. "God be thanked," said the martyr, "who delivereth me at last from the chains of the body." The place of execution was an open space at a little distance outside the city, around which were tall trees. These the crowd of friends who had followed him from the court climbed that they might view the spectacle. Many cried out that they wished to die with their bishop. Having reached the place, Cyprian folded his cloak, knelt upon it, prayed, took off his remaining garments, one by one, till only a linen tunic was left, and awaited so the fatal stroke. In token of forgiveness to his executioner, he ordered 25 denarii of gold (about $30) to be given him. With his own hand he bound the bandage around his eyes, and as the head fell, the crowd caught on handkerchiefs and napkins the drops of blood, which they preserved as sacred relics. His body was interred the following night in the Mappalian way, where a church for many ages marked the spot of his burial. In this church the high festivals of the city were celebrated; and the first care of the general Belisarius, when, 3 centuries later, he entered Carthage on the eve of St. Cyprian, as a deliverer from the Vandals, was to restore this sacred edifice. Another church, called *mensa Cypriani*, was built upon the spot of his martyrdom. The date of his death was Sept. 14, 258; but since the 5th century the day set apart for his festival has been Sept. 16. After the Saracen conquest of Africa, his relics were transported to Arles in France, and subsequently they were distributed in various abbey churches. His festival is kept with much ceremony in the church of St. Maria in Trastevere at Rome, where they show the body of his friend St. Cornelius.—Cyprian's works have been very often published and edited by eminent scholars, almost from the invention of printing. Fell's Oxford edition appeared in 1682; another with notes of Pearson and Dodwell in Holland in 1700. The standard edition is that of Paris, 1726, folio, with the notes of Baluze and the life of the saint by D. Mavan. Cyprian's works have been translated into English by Marshall (London, 1717). Of biographies there are those of Gervaise (1717, 4to.); F. W. Rettberg (Göttingen, 1831, 8vo.); Poole (London, 1840, 8vo.); F. X. Collombet (Paris, 1843); Böhringer (Zurich, 1842, 8vo.).

CYPRUS (Gr. Κυπρος; Turk. *Kebris*), a Turkish island, the most eastern of the Mediterranean, lying at nearly equal distances from the shores of Syria and Asia Minor, extending from Cape Gatto, lat. 34° 29′ 18″, to Cape St. Andrea, lat. 35° 41′ 42″; length about 148 m.; width for 100 m. W. to E. about 40 m., thence to the N. E. extremity about 15 m.; area about 4,500 sq. m.; pop., which under the Venetians amounted

to 1,000,000, now only about 110,000, of whom about 70,000 are Greeks, and the rest Turks, Maronites, Armenians, Roman Catholics, and Jews. It is intersected from E. to W. by a range of mountains, called Olympus by the ancients, whose highest peaks exceed 7,000 feet. The natural productions are of the richest character; aromatic herbs of all kinds grow spontaneously. Cotton, wine, and tobacco, silk and fruit, all of fine quality, are produced. Several dyewoods and drugs are also grown on the island. The minerals are numerous, including the precious metals, and copper and many precious stones, but the mines are neglected. The wines of Cyprus, especially those from the vineyard called the Commanderie, from having belonged to the knights of Malta, enjoyed great celebrity in former times, and the production exceeded 2,000,000 gallons, but has now dwindled down to less than 200,000 gallons. There are 5 qualities of Cyprus wines, viz.: 2 black and red, common wines with a strong taste of tar, from being kept in tarred casks, exported to Egypt, but never to Europe; 2 excellent Muscat and Morocaneller wines, and the Commanderie referred to above. Larnica, where the European consuls and the principal merchants of various nations reside, and Limasol, are the chief commercial emporiums of the island. Famagosta, so famous under the Venetians, possesses an excellent spacious port, which is sheltered from all winds, and which could easily be deepened, when it would accommodate hundreds of large ships; but at present it is choked up with filth to such a degree, that it can only hold about a dozen small craft. The great scourge of the island is locusts, which commit great ravages; but in spite of this evil, and of the abuses in fixing and collecting the taxes, the prosperity of Cyprus is, on the whole, increasing. Many of the oppressions formerly practised upon the peasants have been removed. They are freely permitted to sell their produce, and agricultural employment is abundant. The wheat and oats grown are of an inferior quality, and the annual grain crop does not exceed 120,000 quarters. During the late Russian war, the demand for and high prices of grain led the peasants to neglect the cultivation of cotton, sesamum, and colocynth, but they have since resumed the latter, as the most adapted to the soil. The cotton crop in 1857 amounted to about 11,000 cwt. The olive and wool crop had failed in that year, the latter from a disease among the sheep. Madder root forms a principal production, the greater part being exported to France, and the rest retained for home consumption. The abolition in 1835 of the monopoly on caroulis rapidly increased the production from 4,000 cantars in that year to 40,000 in 1857, 6 cargoes being for the first time exported to England in the latter year. British and American manufactures are imported from Syria, Smyrna, and Constantinople; hides, coffee, sugar, cloth, fowling pieces, fine powder, small shot, salt fish, and Swedish iron, from France; glass, steel, German iron, nails, paper, &c., from Trieste and other Austrian ports. Total annual imports valued at about $150,000; exports at $350,000. The island forms an eyalet, and is governed by a vali or viceroy, and 12 lieutenants preside over the 12 districts into which it is divided. Capital, Nicosia (or Lefkosha), where the Greek archbishop and the provincial authorities reside.—The island of Cyprus occupies a distinguished place both in sacred and profane history. It early belonged to the Phœnicians of the neighboring coast. It was afterward colonized by Greeks, who founded there several independent kingdoms, and passed successively under the power of the Pharaohs, Persians, Ptolemies, and Romans, excepting a short period of independence under Evagoras, in the 4th century B. C. It was one of the chief seats of the worship of Venus, hence called Cypria. Salamis, Citium (whence the biblical name of the island, Kittim), Amathus, Paphos, Soli, &c., were the most remarkable ancient cities. At the time of the crusades it was detached from the Greek empire, and made a kingdom for Guy of Lusignan. (It is in consequence of the claim made by the house of Savoy to the heirship of the Lusignan family that the king of Sardinia still assumes the title of king of Cyprus.) From his descendants it fell to the Venetians, and in 1570–'71 was subdued by the Turks after a brave defence. In 1832 it was occupied by the viceroy of Egypt, but retaken in 1840 by the Turks, under whose rule the island has greatly declined from the splendor and prosperity which gave it world-wide celebrity while held by the Venetians.

CYPSELUS, son of Æëtion, a tyrant of Corinth. His mother was one of the Bacchiadæ, but so ill-favored that none of her own order could be induced to accept her in marriage, whereon she wedded Æëtion. The Delphian pythoness having foretold that her child would prove formidable to the aristocratic party, the Bacchiadæ attempted to murder him; but his mother concealed him in a chest (Gr. κυψελη) till the danger had blown over. Cypselus became a leader of the democracy, with whose assistance he overthrew the power of the oligarchs, and expelled them from the city; but ultimately he became the oppressor alike of nobles and people. He reigned at Corinth 30 years (655–625 B.C.), and was succeeded by his son Periander.

CYRENÆA, or Cyrenaica, an ancient country of Africa, in the N. E. part of modern Tripoli, bounded N. by the Mediterranean, E. by Marmarica, S. by the desert (of Barca), and W. by the Great Syrtis, now gulf of Sidra, in its widest limits including Marmarica on the E., and extending to the Aræ Philenorum on the W., and thus corresponding with modern Barca. The centre of this country is a moderately elevated table-land, gradually and in terraces sloping down to the hilly coast land, which, from its position, climate, and soil, is one of the most delightful regions of the earth. It

abounds in excellent fruits, vegetables, flowers, and rare plants, of which the *silphium*, the *laserpitium* of the Romans, was famous in antiquity both as food and for its medicinal virtues. Cyrenæa was one of the most flourishing colonies of the Greeks, having been settled by Dorians from the island of Thera, the southernmost of the Cyclades, who, under the influence of the climate, soon threw off the rigidity of their race, though continuing in friendship with their kindred of Crete, and became a luxurious people, renowned for skill in chariot driving and games. Battus, the leader of the original colony, founded Cyrene, the chief city, 631 B. C., and a royal dynasty, which numbered 4 princes of his name, including himself, and 4 of the name of Arcesilaus. The comparative independence of Barca, one of the early colonies of Cyrene, and the invasion of the Persians under Cambyses, weakened the last Battiads; a republican form of government was established, but internal dissensions soon led to the restoration of tyranny. When Alexander the Great invaded Egypt, the Cyrenæans were his allies. After his death the first of the Ptolemies annexed their country to Egypt, and his successors possessed it till 95 B. C., when Apion, the last governor, an illegitimate son of Ptolemy Physcon, made it over to the Romans. Under the Ptolemies the country was also known by the name of Pentapolis, being so called from the 5 principal cities: Cyrene; Apollonia, the port town of the preceding; Ptolemais (perhaps identical with Barca), now Tolmeta; Arsinoë, more anciently Teuchira, now Taukra; and Berenice, more anciently Hesperides, now Benghazi, at the mouth of the Lathon. The Romans, who first proclaimed the freedom of the country, soon annexed it as a province, together with Crete, under the name of Cyrenaica. Under Constantine the Great it became a separate province, and was called Upper Libya. The bloody struggles with the revolted Jewish inhabitants under Trajan, repeated incursions of the nomadic tribes of the interior, earthquakes and locusts, gradually destroyed the wealth of the province; its invasion by the Persians, and soon after by the Saracens, in the 7th century, completed its ruin. Cyrenaica was the chief seat of the disciples of Aristippus, and in a later period of the African Gnostics. The whole region abounds in curious remnants of antiquity, which have attracted the attention and scrutiny of modern travellers and critics.—Compare Della Cella, *Viaggio da Tripoli alle frontieri occidentali dell' Egitto* (Genoa, 1819); Pacho, *Voyage dans la Marmarique, la Cyrénaïque*, &c. (Paris, 1825–'29); Beechey, "Proceedings of the Expedition to Explore the Northern Coast of Africa" (London, 1828); Trighe, *Res Cyrenensium* (Copenhagen, 1828); Hamilton, "Wanderings in North Africa;" and Rawlinson's notes to the 4th book of Herodotus.

CYRENAICS, a school of philosophers founded by Aristippus of Cyrenaica, a pupil of Socrates, about 380 B. C., who taught that enjoyment was the highest object, and that virtue consisted in the art of producing the highest possible amount of agreeable feelings, by living in moderate activity, in the enjoyment of art and literature, with the careful shunning of pain. They despised, like the Cynics, all speculative philosophy, but were as a rule not immoral, limiting their practice to a gay, moderate, and amiable enjoyment of life. Among these philosophers, Arete, the daughter of Aristippus, his grandson Aristippus Metrodidactus, and Hegesias, were the most renowned. This school was succeeded, a century later, by the kindred philosophy of Epicurus.

CYRENE, chief city of Cyrenæa or Cyrenaica, founded in 631 B. C. by Theræans under Battus, around a fountain (κρηνη) consecrated to Apollo, which supplied the city with water, was built on a high terrace of the Cyrenæan tableland, about 9 m. from the coast at Apollonia, which became its port. The road which connected the city with the harbor, a vast necropolis, and ruins of streets, temples, theatres, tombs, and remnants of art, are still visible, the site of the ancient city having been identified with the modern Grennah. The British traveller Hamilton speaks of the neighborhood of this place as "abounding with beautiful scenes, some of which exceed in richness of vegetation, and equal in grandeur, any thing that is to be found in the Apennines, . . . some offering perhaps the most lovely sylvan scenery in the world." In the time of Herodotus Cyrene covered an area equal to the entire neighboring island of Platea (now Bomba). Aristippus, the founder of the Cyrenaic school of philosophy, Carneades, the founder of the New Academy, the poet Callimachus, the astronomer Eratosthenes, and the eloquent Christian bishop Synesius (in the 5th century), were natives of Cyrene.

CYRIL OF ALEXANDRIA, saint and patriarch of the church, born about A. D. 376, died in 444. Theophilus, bishop of Alexandria, was his uncle and teacher; and after the death of the latter in 412, the succession in the bishopric was given to Cyril. Alexandria at this time was one of the 4 principal seats of ecclesiastical power. Its bishops bore the title of patriarch. Cyril at once undertook to suppress heresy and drive out from the city all unbelievers. He attacked the Novatians, shut up their churches, seized their sacred vessels, and compelled them to silence. A popular outbreak gave him pretext for banishing the Jews, who had lived there unmolested for many centuries, and were wealthy, cultivated, and important to the prosperity of the city. Though the governor Orestes opposed him in this act of zeal, he was sustained by the emperor and by the Christian populace. The famous Hypatia, the female Platonist of Alexandria, was torn in pieces in the street by the people, from the report or suspicion that she encouraged the governor in his opposition to the bishop. The progress of the Nestorian heresy next attracted

Cyril's attention. This heresy, which denied the orthodox theory of the incarnation, had gained influence among the cenobites of Egypt, not only from its subtle reasonings, but from the ascetic virtues of its author, the bishop of Constantinople. Cyril sent severe letters to Nestorius, calling upon him to retract his falsehoods; which proved, as might be expected, ineffectual. An appeal to the bishop of Rome, though it resulted in a justification of the course of the Alexandrine bishop, forced no retraction from the Byzantine. Nestorius would not pronounce his former propositions to be accursed. A council was called at Ephesus, in which Cyril as legate and prosecutor took the lead, and the recusant Nestorius was deposed and condemned. A subsequent *ex parte* council of 42 bishops, headed by John, patriarch of Antioch, judged the case differently, and, favoring Nestorius, excommunicated and deposed his opponent and the Alexandrine party. The emperor, appealed to in this strait, condemned both sides and ordered the rival champions to be imprisoned. The powerful intercession of Rome, however, soon caused this sentence against Cyril to be abrogated, and the patriarch returned home. Nestorius was sent to a convent near Antioch, and finally to Upper Egypt, and Cyril could spend the last 12 years of his episcopate in the faith that he had vanquished the heretics of his province and exterminated infidelity. After the banishment of Nestorius, his word as expounder of the faith remained undisputed.—His writings are mostly controversial. They are marked by a rugged earnestness of style, with little grace or beauty, and by positiveness of statement rather than by cogency of argument. His expository works consist of 17 books on "Worship in Spirit and Truth;" 13 books of "Glaphyrs," which are commentaries on various passages in the Pentateuch; a series of commentaries on Isaiah; and 12 books of notes upon John's Gospel, some of which are imperfect. The method of these is thoroughly allegorical. His ethical and ritual works are contained in 29 discourses for Easter week, in which he uses language that seems not only to teach transubstantiation, but to prophesy the worship of the Virgin Mary. His polemical works are: a work against the Arians, called the "Treasure," in 35 sections; 7 dialogues on the "Trinity," 2 on the "Incarnation;" 3 treatises on the "Right Faith;" 5 books against Nestorius, in which the heresies of that teacher are discussed without mentioning his name; 12 "Anathematisms," sent directly to Nestorius, and 3 "Apologies" for these "Anathematisms," defending them from the charges of heresy and of ambiguity, which had been brought against them. All these works were brought out by the Nestorian controversy. Beside these, Cyril wrote a book against the "Anthropomorphite" monks, who held that God had a physical body, in answer to 27 dogmatical questions which they had put to him; 2 letters against Theodore of Mopsuestia; and 10 books against Julian the emperor, in answer to the 3 books which that sovereign had published against the Christians. This last work is one of the most curious monuments of Christian polemic literature. It vindicates the Mosaic cosmogony against the Grecian theories, the theogony of the Bible against that of Hesiod, monotheism against polytheism, the unity of the Deity against the charge of duality, exalts the Christian prophets and martyrs above all the heathen philosophers, gives as a reason for the downfall of the heathen oracles that "the devil was restrained by Christ's coming," explains the Christian reverence for the wood of the true cross and for the tombs of martyrs, and discriminates this from the pagan idolatry. Many letters, too, of his large correspondence have survived, and some treatises upon "The Faith," dedicated to the sisters of the emperor.—Parts of the works of Cyril have been frequently translated into Latin. The best edition is that of John Aubert, canon of Laon (6 vols. folio, Paris, 1638), printed both in Greek and Latin. Beside this, there is the Cologne folio (2 vols. 1546), and another Paris edition (2 vols. folio, 1692), the Greek text with notes. The character of Cyril is drawn in the historical romance of "Hypatia," by Charles Kingsley (London, 1853).

CYRIL OF JERUSALEM, saint and archbishop of the church, born at or near Jerusalem, about A. D. 315, died in 386. He was about 30 years old when he was ordained priest by Maximus, bishop of Jerusalem, and was intrusted with the charge of the catechumens, and sometimes with the duty of preaching in the place of the bishop. When, in 350, the see of Jerusalem became vacant, Cyril was promoted to that place, and consecrated by Acacius of Cæsarea, the metropolitan of Palestine. Acacius was an Arian, and it has been affirmed that Cyril, in keeping fellowship with him and the Arian party, while he himself professed orthodox sentiments, was guilty of duplicity. He was never, however, considered to be Arian by the Arians themselves, or in any way favorable to that party in the matter of theology, although in his banishment and misfortune he accepted the hospitality of friends who were semi-Arian. Acacius was for many years his bitter enemy and persecutor. In the year 357, taking advantage of a technical violation of the canon law, Acacius procured a sentence of deposition against the orthodox bishop. Cyril was accused of having sold the furniture and ornaments of his church, gifts of the emperor Constantine; but his plea was that he did this to save the poor from starving in a time of famine. The sentence, palpably unjust, was reversed at the council of Seleucia in 359, but was the next year repronounced, with an additional imperial decree of banishment. On the accession of Julian, in 361, Cyril was enabled to return to Jerusalem. The favor of the tolerant pagan did not, nevertheless, prevent the Christian zeal of the bishop; and he did not hesitate to condemn, on grounds of Scripture

and prophecy, the emperor's attempt to rebuild in the holy city the Jewish temple. The edict of the emperor Valens in the year 367, repealing Julian's act of amnesty, again sent Cyril into exile, and only after 11 years was he able to regain his seat and to stay unmolested. He had the satisfaction in the last years of his life of seeing the orthodox faith fully established, and of taking part in the council of Constantinople, which decreed the condemnation of the Arian, semi-Arian, and Macedonian heretics.—The writings of Cyril which remain are: a course of 23 "Catechetical Lectures;" a single sermon, suggested by the Scripture narrative of the healing of the paralytic, and treating sin as the origin of all misery and suffering; and a letter to the emperor Constantine relating the prodigy of the luminous cross at Jerusalem. His works have been frequently printed both in Greek and in Latin. The editions of Cologne (1564) and Paris (1589) are in a single octavo volume. The fine edition of the Benedictine Touttée (Paris, folio, 1720) is in both languages. A French translation of the "Catechetical Lectures," with notes and commentaries, was made by Grandcolas. An English translation of the same work, very faithful and spirited, edited by John Henry Newman, was published in Oxford in 1838.

CYRUS, the ancient name of a river in Asia. See Koor.

CYRUS. I. The Elder, the Koresh of the Hebrew Scriptures (supposed to be from the Persian *kohr*, the sun), the founder of the Persian empire, reigned from 559 to 529 B. C. He was grandson of Astyages, king of Media. This is one of the few particulars of his life about which the various testimonies of antiquity agree, most others being differently related in the histories of Ctesias and Herodotus, and in the Cyropædia of Xenophon. But as Ctesias is in general little trustworthy, and as Xenophon seems to have written his book, a kind of philosophical romance, for moral or political purposes, and without much regard for history, the story of Herodotus, in spite of its legendary character, has been generally adopted by modern historians down to Grote. According to this narrative, Cyrus was the son of Cambyses, a Persian noble, and of Mandane, the daughter of Astyages. This king commanded him to be put to death immediately after his birth, in consequence of some dreams which were explained by the magi as presages of the future royal greatness of the child. Saved by the humanity of Harpagus, an officer of the court, and of a herdsman, who was to expose him to death in the wilderness, he was brought up by the latter, as his son, in a secluded mountain region, where he soon became the leader of his playfellows, who chose him as their king. Having in this capacity ordered the son of a distinguished Median to be scourged for disobedience, he was brought before Astyages, to whom his bold answers and his features soon betrayed his origin. The herdsman was pardoned, Harpagus cruelly punished in the person of his son, and Cyrus, whom the magi declared to have already attained the threatening greatness predicted by the dreams, was sent to Persia to his parents. When he grew up, following the secret advice of Harpagus, he prepared to dethrone his grandfather. The Persians, a poor, hardy, and warlike people, were easily induced to shake off the yoke of Media; Harpagus betrayed the first army, sent under his command against the rebels; and with a second, the king himself was defeated near Pasargada, and made prisoner (559). Cyrus was acknowledged by the Medes as ruler of the new empire of Persia and Media, of which they became the second nation. He now marched against Crœsus, the rich and mighty king of Lydia, who crossed the Halys to revenge his fallen ally and brother-in-law Astyages. A bloody battle was fought in Cappadocia, but with an indecisive result. Crœsus, however, thought it wiser to return to his own country, hoping to recommence the campaign with reënforcements from his allies, the kings of Egypt and Babylonia, and the Lacedæmonians. But before these arrived, Cyrus had in his turn crossed the Halys, vanquished the celebrated Lydian cavalry on the plain before Sardis, taken that city, and made Crœsus his prisoner. The Greeks of Asia Minor, who had rejected the previous invitations of Cyrus to revolt against the Lydians, were now conquered by an army under Harpagus. A part of the Phocæans, however, preferred the dangers of an emigration to the distant regions of the west to a peaceful subjection. The Carians, Caunians, Lycians, and others were next subdued by the same general, while Cyrus himself was preparing and partly executing his more important eastern conquests. For the reduction of Babylonia, the 2d great empire of western Asia, by Cyrus, we have the concurring testimony of the 3 above mentioned Greek historians, as well as of the Scriptures, though, according to Xenophon, he acted only as general of his uncle Cyaxares II., son of Astyages, king of Media. Herodotus describes in his way how, on his march from the north-east against Babylon, Cyrus chastised the river Gyndes, an affluent of the Tigris, for drowning one of his sacred white horses, by digging 360 channels "so that women in future should cross it without wetting their knees;" how he turned the Euphrates by a canal into the artificial lake made by the Babylonian queen Nitocris, "on which the river sank to such an extent, that the natural bed of the stream became fordable;" how through this bed the Persians entered the city and took it by surprise; and how, "owing to the vast size of the place, the inhabitants of the central parts (as the residents at Babylon declare), long after the outer portions of the town were taken, knew nothing of what had chanced, but as they were engaged in a festival, continued dancing and revelling until they learned the capture but too certainly." Confirming these statements, the Hebrews dwell with pleasure

on the exploits of their deliverer from the Babylonish captivity; on the "one from the north" and "from the rising of the sun," who comes "upon princes as upon mortar, and as the potter treadeth clay," who executes "on Babylon the vengeance of the Lord," "that saith to the deep, Be dry, and I will dry up thy rivers; that saith of Cyrus, He is my shepherd and shall perform all my pleasure; even saying to Jerusalem, Thou shalt be built; and to the temple, Thy foundation shall be laid" (Isaiah). They delight to relate how "the mighty men of Babylon have forborne to fight, they have remained in their holds, their might hath failed; they became as women;" how one post runs "to meet another, and one messenger to meet another, to show the king of Babylon that his city is taken at one end" (Jeremiah). After the fall of the capital (538), which seems to have been greeted by many oppressed nations of Asia as the commencement of an era of justice and freedom, all the provinces of the Babylonian empire speedily surrendered to the conqueror, who was now master of nearly all the countries between the Indus and the Ægæan, the Oxus and the Red sea. Satisfied with this vast dominion, which he ruled wisely and justly, Xenophon makes him die in peace and in his bed with a Socratic speech on his lips; but Arrian attributes to him afterward an invasion of India across the desert of Arachosia; Ctesias, an expedition against the Derbices, a people in the Caucasian regions, in which he is slain; and Herodotus, an attack upon the Massagetæ, northern nomades ruled by a queen, Tomyris, and greatly resembling the Scythians, in whose country he was defeated and slain in a bloody battle. Tomyris, who revenged the death of her son, filled a skin with human blood, Herodotus adds, into which she dipped the head of Cyrus, thus giving the insatiable conqueror, as she said, his fill of blood. There is, however, some testimony to the allegation that he was buried in Pasargada in his native province, "where his tomb was honored and watched until the breaking up of the empire, while his memory was held in profound veneration among the Persians." "There is much reason to believe," says Rawlinson, "that the tomb of Cyrus still exists at Murgab, the ancient Pasargada. On a square base, composed of immense blocks of white marble, rising in steps, stands a structure so closely resembling the description of Arrian, that it seems scarcely possible to doubt that it is the tomb which in Alexander's time contained the body of Cyrus. It is a quadrangular edifice or chamber, built of blocks 5 feet thick, which are shaped at the top into a sloping roof. Internally the chamber is 10 feet long, 7 wide, and 8 high. There are holes in the marble floor, which seem to have admitted the fastenings of a sarcophagus. The tomb stands in an area marked out by pillars, where occurs repeatedly the inscription (written both in Persian and the so-called Median): 'I am Cyrus the king, the Achæmenian.' It is called by the natives the tomb of the mother of Solomon." II. Cyrus the Younger, 2d son of Darius Nothus, king of Persia, received from his father at an early age the satrapy of Lydia, Phrygia, and other parts of Asia Minor (407 B. C.). When his elder brother, Artaxerxes II., ascended the throne (404), he formed a plot against his life, which was discovered by Tissaphernes, and pardoned on the intercession of Parysatis, the widow of Darius. Reinstated in his satrapy, Cyrus succeeded in collecting a powerful army, including 13,000 Greek mercenaries, and marched from Sardis in the spring of 401 toward Babylonia, with the secret purpose of dethroning his brother. Having crossed the Euphrates at Thapsacus, he met the king at the head of an immense army, near Cunaxa. The battle was nearly won, especially by the valor of the Greeks on the right wing, when, perceiving Artaxerxes in the centre, the ambitious prince furiously rushed to assail him, and fell pierced by a javelin, after having wounded his brother. The character and accomplishments of this prince are painted in the brightest colors by Xenophon, in the 1st book of the Anabasis.

CYTHERA. See Cerigo.

CYZICUS, one of the oldest and most powerful of the Greek cities of Asia, situated on a small island in the Propontis, near the Mysian shore, is said to have been founded by a Pelasgic tribe, expelled from their homes by the Æolians. It was afterward subject alternately to Athens, Sparta, and Persia, and obtained its independence after the time of Alexander. In the wars which determined the fate of the kingdom of Syria it took part with Pergamus and the Romans against Antiochus. The heroism with which the Cyzicenes defended their city when it was besieged by Mithridates obtained for it the rank of a *libera civitas*. When Constantine created the new province of Hellespontus, he made Cyzicus the capital. It was partially destroyed by an earthquake in A. D. 443, and was captured and completely ruined by the Arabians in 675. The place is now overgrown with neglected orchards and vineyards, and a low sandy isthmus has been formed, converting the island into a peninsula.

CZACKI, Tadeusz, a Polish financier and author, born in 1765, at Poryck, in Volhynia, died at Dubno, Feb. 8, 1813. At an early age King Stanislas Augustus appointed him to an office in the royal tribunal of Warsaw, where the regulation of the secret archives of the Polish sovereigns was intrusted to him. From 1788 to 1795 he was a member of the Polish board of the treasury. He was also employed by the committee which discussed the constitution of May 3, 1791, of which he was a staunch supporter. When the second division of Poland took place, his property was confiscated, but afterward restored by Paul I. In the latter part of his life he devoted himself to the interests of education. His views met with the approbation of Alexander, and the gymnasium of

Kremenetz, in Volhynia, of which he was the founder, was opened in 1805. The instruction in this school gave umbrage to the government; but on being, in 1807, summoned to St. Petersburg, he succeeded not only in making his vindication acceptable to the czar, but was appointed curator of the public schools of western Poland. His complete works, which are mostly historical, were published in 3 vols., in Posen, in 1843–'45; the most important being his book "Of the Laws of Poland and Lithuania."

CZAJKOWSKI, Michał, a Polish novelist (now Sadik Pasha, a general in the Turkish army), born in 1808 in the Ukraine. His enthusiasm was kindled by the writings of Adam Mickiewicz, with whose romantic spirit his novels, which chiefly treat of Cossack and of Ukrainian life, are deeply imbued. After the Polish revolution of 1830, in which he had taken a part, he betook himself to Paris. In 1840 he was sent by Prince Czartoryski on a mission to Turkey, but at the instigation of Russia he was compelled to relinquish this office, and would have been banished from the Turkish territory if, at the beginning of 1851, he had not become a convert to Islamism under the name of Mohammed Sadik Effendi. In the war with Russia he organized and commanded a body of troops under the name of Cossacks of the sultan. After the expulsion of the Russians from the Danubian principalities he was made military governor of Bucharest, and commander of the Turkish army under Omar Pasha in Bessarabia. His novels, of which *Wernyhora* is the most esteemed, have been translated into several languages, and a French translation appeared in Paris in 1857, under the title of *Contes Cosaques*.

CZAR, or Tzar, a title of the sovereigns of Russia, meaning king or lord. It has been supposed by some to be an imitation or corruption of the Latin Cæsar, in the sense of the German *Kaiser*, but the ancient Slavic translation of the Bible has *kesar* for Καισαρ, and *tzar* for king. Karamsin therefore, and others after him, compare the term with the syllable *sar* found in the names of the Assyrian and Babylonian monarchs Phalassar (Pileser), Nabonassar, and Nabopolassar, and with the Hebrew *sar* (commander, chief). The Mongols used the same appellation, and it is probably from them that the Russians adopted it. It is used by Russian annalists as early as the 12th century; but as the official title of the monarchs of Russia it dates from the 16th. Before this period they styled themselves grand princes (*velikoi kniazh*) of Kiev, Novgorod, Vladimir, Moscow, &c. Basil Ivanovitch assumed in 1505 the title of *samoderzhetz*, or autocrat; his son Ivan the Terrible was crowned in 1547 as czar. After the annexation of Smolensk and the Ukraine, the title of czar of Moscow was changed into that of czar of Great, White, and Little Russia (of all the Russias). Though the word czar was used by the Russians also to designate the emperors of the West, as well as of the East (hence the name Tzargorod, city of the emperor for Constantinople), Peter the Great, in order to be without contradiction ranked among the monarchs of the highest category, assumed in 1721 in addition the title of *imperator*, or emperor. In the long negotiations for the acknowledgment of this dignity, which was contested by many states of Europe, it was proved that Maximilian I., who in 1514 concluded a treaty of alliance with Russia against Poland, had used the term emperor (*Kaiser*) for czar, and that the same was done by other powers in the 16th and 17th centuries. It was not, however, till the reign of Catharine II. that Poland, Spain, and Turkey acknowledged the imperial dignity of Russia. The wife of the czar was anciently called *tzaritza;* his sons had the title of *tzarevitch*, his daughters that of *tzarevna*. Since the death of the unhappy Alexei, however, the latter appellations have been replaced by those of grand prince and grand princess. Constantine, the 2d son of Paul I., received in 1799 the title of *tzesarevitch*, which was bestowed after his death in 1831, by the emperor Nicholas, upon his own son Alexander (now the reigning emperor). The wife of the latter received the title of *tzesarevna*. The crown prince Nicholas Alexandrovitch, born in 1843, now bears the former title. The empress is styled in Russian *imperatritza*. The popular Russian appellation of the sovereign is still czar, or *hossoodar* (*hospodar*, lord). Czar was also the ancient title of the princes of Grusia, or Georgia, and Imeritia, now Russian provinces.

CZARNIECKI, or Czarnecki, Stefan, a Polish general, born at Czarnca, in the palatinate of Sandomierz, in 1599, died at Sokolówka in Volhynia, in 1665. Of a noble but poor family, he studied at the university of Cracow, entered the army, and met with little advancement before the outbreak of the great Cossack rebellion in 1648. Having been made captive in the battle at the Yellow Waters (May 25, 1648), he was delivered by Chmielnicki, the leader of the Cossacks, to the Tartars, but set free after the pacification of Zborów, in the following year. He fought in the long and bloody battle at Beresteczko, June, 1651, in which the Cossacks and their allies, the Tartars, were defeated. The period of reverses which followed the defeat of the Poles under Kalinowski, at Batów, by the Cossacks, the incursions of these rebels, the invasion of the Muscovites from the east, of Charles Gustavus of Sweden from the north, and of Rákóczy, prince of Transylvania, from the south, called Czarniecki to greater activity. In 1655 he defended the castle of Cracow with the utmost bravery against the king of Sweden, but was compelled by want of food to surrender. After the repulse of the Swedes from Czenstochowa he collected the scattered remains of the Polish troops, formed the confederation of Tyszowce with John Sobieski and others, and commenced a brilliant and successful course of guerrilla warfare against the Swedes, who had conquered the greatest part of the country, and before whom the patriotic but feeble king, John Casimir, had fled to Silesia. In the early part

of 1656, with the assistance of 5,000 Tartars, he defeated them in 4 battles, brought back the king in triumph, and turned his arms with similar success against the Transylvanians. The dignity of palatine of Red Russia, and the title of "Liberator of Poland," were his reward. In 1658 he marched to the assistance of Frederic III. king of Denmark, who had invaded the German possessions of Sweden; he conquered the island of Alsen, took the command against the Russians, hastened to Lithuania, and won 2 great victories at Polonka, near Slonim, June 26, 1660, and on the banks of the Dnieper, over Chavanskoi and Dolgorouki. Peace was now conquered with Sweden (1660), and Moscow (1661). Having been made *starosta* of Tykocin, he undertook to chastise the Cossacks, who, incited and supported by the Russians, had again commenced their devastations (1663); and in order to procure the assistance of the Tartar khan he set out with only 13 horsemen, following the course of the Dniester, hastened through Bessarabia and the Ukraine to the Crimea, and defeated the Cossacks at Czehryn (1664), and Stawiszcze (1665). But these exertions exhausted him; returning to Tykocin, he could not be carried beyond the village of Sokolówka, where he died in a peasant's hut, having received a few days before the staff of hetman of the crown. In 1760 John Clement Branicki, his descendant, caused a statue to be erected to his memory.

CZARTORYSKI, the name of a Polish princely family, whose origin is traced back to Korygiello or Constantine of Tchernigov, son of Olgierd, duke of Lithuania, and half brother of Jagiello, the founder of the dynasty of that name in Poland (1386). The name is derived from the dominion of Czartorya, and the place Czartorysk near Luck in Volhynia. Of the 2 branches of the family, which belongs to the highest rank of nobility in their country, and boasts of a number of statesmen equally remarkable for wealth, talents, and patriotism, the male line of the younger branch, that of Korzek, became extinct in 1810, while the elder, that of Zukow, is still flourishing in a number of conspicuous persons of both sexes. To this elder branch belong the following historical persons: I. Michał Fryderyk, born in 1695, died at Warsaw, Aug. 13, 1775. He was made castellan of Wilna in 1720, vice-chancellor of Lithuania in 1724, and great chancellor of that duchy in 1752. Together with his brother and other nobles, he formed an influential party, which strove to bring about a reform of the constitution of Poland, which would strengthen the influence of the king and the judiciary, and restrain the anarchical independence of the high dignitaries of the crown. Their chief object was to change Poland into a hereditary kingdom, if possible under a Czartoryski. To counterbalance the influence of the reigning house of Saxony, as well as that of Austria, they courted the assistance of Russia, which by means of gold and bayonets, however, finally decided the matter in its own favor. II. August Alexander, brother of the preceding, born in 1697, died at Warsaw in 1782. He was palatine of Red Russia, and lieutenant-general of the army of the crown. He was a zealous coöperator with his brother, but was deceived in the expectation of seating his son upon the throne of his country. By activity and happy speculations he added greatly to the wealth of the family. III. Adam Kazimierz, son of the preceding, born Dec. 1, 1731, at Dantzic, died March 19, 1823, at Sieniawa in Galicia. He was chosen by the party which was headed by his father and uncle as candidate for the royal dignity after the death of Augustus III. (1763). To gain the assistance of Russia, Stanislas Poniatowski, whose mother was a sister of the 2 elder Czartoryskis, was sent to the court of St. Petersburg. But the empress Catharine II. determined to put the crown of Poland upon the head of her favorite Poniatowski himself. This determination being known, Czartoryski yielded his pretensions to his happier rival, to whom from his early youth he had been attached as a friend. At the assembly of the nation preceding the election, the Czartoryskis and their adherents appeared in great numbers at Warsaw, and together with them an army of Russians, sent to support the claims of Poniatowski. Adam Kazimierz was chosen marshal or president of the diet in spite of patriotic opposition roused by the presence of the Russians, and Poniatowski was elected king. After the first partition of Poland in 1772, Czartoryski, who possessed large estates in Galicia, accepted the commission of a general of artillery in the Austrian army, but still adhered to the party which worked for the restoration of the power of Poland through a constitutional reform, and distinguished himself by his zeal and activity at the long diet, which proclaimed the liberal constitution of May 3, 1791. He was also active in persuading the elector of Saxony to accept the hereditary succession to the crown of Poland, and Austria to engage in an alliance against Russia. But all these attempts failed; the confederation of Targovitza against the new constitution was assisted by the arms of Russia, Poniatowski deserted the cause of the reform, and in 1793 a new partition of Poland ensued. Czartoryski now retired and lived at Vienna during the great rising under Kosciuszko (1794), whom he persuaded not to extend the insurrection over the frontiers of Austria; which, however, did not prevent that power from taking its share at the final dismemberment of Poland in 1795. He took no part in the events which followed the treaty of Tilsit, and the creation of the duchy of Warsaw by Napoleon (1807); but in 1812 he accepted the marshalship of the confederation, preceding the invasion of Russia, which promised the restoration of ancient Poland. This illusion, however, soon vanished; Napoleon wanted the Poles, but no Poland, and the fatal issue of the great campaign foiled every hope. Czartoryski retired to Pulawy, but in 1815 headed a depu-

tation to the congress of Vienna, and presented to the emperor Alexander the outlines of a new constitution for the kingdom of Poland, now reorganized under his sceptre. Alexander made him senator palatine. IV. Elzbieta, wife of the preceding, born countess of Flemming in 1743, died in Galicia, June 17, 1835. She was distinguished by beauty, spirit, and patriotism, but also inclined to romantic extravagance. Having spent several years at court, and in travels in western Europe, which brought her into contact with the most remarkable personages of the age, she retired to Pulawy, where she constructed the admirable gardens of which Delille sings in the didactic poem *Les jardins*, and the temple of the sibyl, containing a collection of relics of Polish history. She was also active in promoting industry and education. She published "Ideas on the Construction of Gardens" (Breslau, 1807), and the "Pilgrim in Dobromil" (Warsaw, 1818), a popular book on national history, for the instruction of the agricultural class. Having survived the 3 partitions and 2 restorations of Poland, she proved her patriotism in the revolution of 1830–'31, but had the mortification to see her seat at Pulawy bombarded by her own grandson, the prince of Würtemberg, who served in the Russian army. She passed her last years with her daughter in Galicia. The collections of Pulawy were in part dispersed, and in part transported to St. Petersburg. V. Marya Anna, daughter of the preceding, born March 15, 1768, died at Paris, Oct. 24, 1854. In 1784 she was married to Louis Frederic Alexandre, prince of Würtemberg, but as he betrayed the cause of Poland in 1792, she left him and was divorced. Her mother in one of her letters characterizes her in these words: "A heavenly soul, an angelic character, a charming figure, talents, virtues, and many misfortunes—this is her history." In 1816 she published a romance, *Malwina*, which was translated into several languages. After the revolution of 1830–'31 she retired to Galicia. The estates of the Czartoryskis in the kingdom of Poland having been confiscated, her only son Adam, prince of Würtemberg, who had served against the Poles, offered her a pension, which she rejected in the following words: "Sir, I have not the honor of knowing you; I have no longer a son, and care little for fortune." VI. Adam Jerzy, brother of the preceding, born Jan. 14, 1770, completed his education in France and at the university of Edinburgh, fought bravely in 1792 against the Russians, in the Lithuanian army under Zabiello, and was sent in 1795 to the court of St. Petersburg, as a hostage for the fidelity of his family. There, being attached to the person of the grand duke Alexander, the future emperor, he became his intimate friend. In 1792 he was sent by the emperor Paul as ambassador to the court of Sardinia, whence he was recalled in 1802 by his successor Alexander, to assist him in the department of foreign affairs. This situation, which he accepted, and used for the benefit of his country, drew upon him a great deal of envy and patriotic censure on the part of some of his countrymen, which, however, his conduct gradually overcame. On April 11, 1805, he signed for Russia the alliance with England, and accompanied Alexander in the campaign in Austria, where he was present at the battle of Austerlitz. He also followed him to the campaign in Prussia, and after its termination to the conferences of Tilsit in 1807. The duchy of Warsaw having been created by the treaty then concluded, he left the service of the emperor and lived retired from public affairs till 1813, when he again accompanied Alexander to Germany, France, and the congress of Vienna. Made senator palatine of the new kingdom of Poland by Alexander, he appeared at its first diet, acting in behalf of liberal ideas. In 1821 he resigned the curatorship of the university of Wilna, which he had held since its organization in 1803, in consequence of the extraordinary persecutions to which a number of students, accused of conspiracy, had been subjected. The report of his successor Novosiltzoff, who accused him of having delayed for a century, through his management, the amalgamation of Lithuania with Russia, was an honorable testimony to his patriotism. He now more and more won the confidence and esteem of the nation, and after the outbreak of the revolution of Nov. 29, 1830, he was called to preside over the provisional government. He convoked for Dec. 18 the diet which proclaimed the independence of Poland, Jan. 25, 1831, when Czartoryski became president of the national government. This dignity, in which he sacrificed immense riches on the altar of the revolution, he laid down after the terroristic scenes of Aug. 15, to serve as a private soldier in the ranks of the army under Ramorino. After the surrender of that general in Galicia, and the fall of Warsaw (Sept. 1831), he shared the fate of the Polish emigration in France. He was excluded from the amnesty of 1831; his estates in the Russian Polish provinces were confiscated; those in Austria were sequestered in 1846 in consequence of a declaration in favor of the revolutionary movement which drove the Austrians from Cracow, but were restored in 1848. In March, 1848, he issued a proclamation calling upon the representatives of Germany and France to unite for the restoration of Poland. In April of the same year he abolished serfdom on his estates of Sieniawa. Being the choice of the monarchical party in the Polish emigration, and as such distinguished by some too zealous adherents with honors not convenient for an exile, Czartoryski was often the object of violent attacks on the part of the democrats, but together with his wife, Anna, princess of Sapieha (born in 1796), sustained his dignified position by a nearly regal munificence, which made his hotel in Paris a place of refuge for his suffering compatriots. He has 2 sons, Witold, born in 1824, and Wladyslaw, born in 1828, and a

daughter Izabella, born in 1832. VII. Konstanty, brother of the preceding, born Oct. 28, 1773, was sent in 1795 together with his brother as hostage to St. Petersburg, where he was attached to the person of the grand duke Constantine Paulovitch. Having returned to Poland, he was made colonel in the army of the duchy of Warsaw in 1809, and followed the army of Napoleon to Russia in 1812. After the retreat from Moscow he retired to Austria, and has since taken no part in public affairs. He has 4 sons.

CZASLAU. I. A circle or administrative province of Bohemia; area 1,260 sq. m.; pop. 247,087. It is traversed by the Moravian mountains, in which rise several tributaries of the Moldau and the Elbe. The high lands are well wooded, and the plains and valleys are extremely fertile. Gold, silver, iron, saltpetre, and precious stones, particularly garnets, are found in some districts. There are manufactories of cotton, woollen, and paper. II. Capital of the above circle, pop. 3,500, memorable for a victory over the Austrians gained by Frederic the Great, May 17, 1742. It has a church noted for its lofty spire, and containing the tomb of Ziska, the Hussite leader.

CZECZ, János, a Hungarian general, born at Zsidófalva, in Transylvania, in 1822, was attached in 1846 to the Austrian general staff, and in June, 1848, to the newly created Hungarian ministry of war, served successively under Mészáros in southern Hungary, as reporter of the revolutionary committee of defence headed by Kossuth, and under Bem in Transylvania, where he contributed to the reorganization of the army, as well as to the victories of that general. After the catastrophe of Világos, he succeeded in escaping to Hamburg and London. His "Transylvanian Campaign of Bem" (Hamburg, 1850) is a valuable contribution to the history of that eventful war.

CZEGLÉD, a large market town in the co. of Pesth, in Hungary, on the Pesth-Szolnok railroad, pop. about 15,000, situated in a fertile district which produces much grain, and some red wine. It has a Roman Catholic and a Calvinist church. The inhabitants are mostly Magyars, and agriculturists. The proximity of Kecskemét, Szolnok, and the Theiss, made Czegléd conspicuous during the Hungarian war of 1848–'49, particularly in Jan. 1849, when the offensive against the Austrians was recommenced under Perczel.

CZENSTOCHOWA, or Czenstochau, a town of Russian Poland, in the government of Kalisz, near the Prussian frontier, is situated on the Warta, and on the Cracow and Warsaw railroad line, and consists of the old and new town, and the suburb St. Barbara; pop. about 8,000, of whom about the 8th part are Jews. Its chief manufacture consists in chaplets and images made for the numerous hosts of pilgrims from all parts of Poland and other Slavic countries, who annually visit the shrine of the monastery of St. Paul, situated on the Klarenberg (Pol. *Jasna Góra*), between the old and new towns, and containing a dark brown image of the Virgin, the miraculous power of which is a matter of general belief among the Slavic people. The monastery, having been pillaged by the Hussites in the 15th century, was fortified, and afterward withstood in 1655 a siege of the Swedes of Charles Gustavus, who had occupied the whole country, and were here repulsed by a few friars; was bravely defended by the confederates of Bar under Pulaski in 1771, when the old town was reduced to ashes; was taken by the French in 1806, newly fortified by them in 1812, and finally given up to the Russians, who destroyed the fortifications.

CZERNIGOW. See Tchernigov.

CZERNOWITZ, Tchernowitz, or more properly Czernowice. I. A circle of Austrian Galicia, also called the Bukovina; pop. about 300,000. It is a mountainous but fertile region, comprising an area of 3,097 sq. m., covered with ridges of the Carpathian system, and everywhere broken into hills and valleys. It is watered by the Pruth and the Sereth. The chief productions are grain, cattle, swine, honey, wax, copper, and lead. There are vast forests of oak, beech, and other timber. The majority of the inhabitants are of Wallachian origin; the remainder are Germans, Russians, and Armenians. II. Capital of the above circle, pop. about 12,000, pleasantly situated on a hill overhanging the Pruth, contains a Greek cathedral, a gymnasium, and high schools. It is neatly built, with wide, clean streets, and gardens and vineyards attached to each house. The principal manufactures are of clocks, silver ware, hardware, and carriages.

CZERNY GEORGE, or Kara George (literally Black George, *czerny* in Slavic, and *kara* in Turkish, signifying black), the leader of the Servians in their insurrection against the Turks, and their chief during the first period of their national restoration, born about 1770, strangled and beheaded in July, 1817. Brought up as a peasant in one of the wild mountain regions of Servia, stern and robust, he evinced while a youth, according to the rather legendary relations of his early life, the courage and fanaticism of his race by the murder of a Mussulman. He served in the Austrian army in the war against Turkey, undertaken by Joseph II., together with Catharine II. of Russia, but soon left the service in consequence of insubordination, and fled into his native mountains, where he became the chieftain of a band of outlaws, who sought to satisfy their thirst for rapine and revenge by pillaging and murdering the Mohammedan oppressors of their country. Tired of this roving life, he reconciled himself with his colonel and followed him to Austria. Under the humane administration of Hadji Mustapha Pasha he returned to his home, where he acquired some property as a grazier, and great popularity by his energy. But the pasha was soon murdered by the janizaries, who now deposed the Turkish authorities and pillaged the Christian natives.

Threatened with the vengeance of the sultan, they resolved to obviate it by the massacre of all the leading Servians, which they executed in part in February, 1804. George and many others escaped and found refuge in the mountains, where they were soon joined by hosts of outlaws, ready to revenge the blood of the Christians. A general insurrection was prepared. George was urged by his companions to become its leader, but, conscious of his ignorance, for he could neither write nor read, he refused, declaring himself incapable of government. "We'll assist you with our advice," was their reply. "But I am of a violent spirit," said he; "instead of judging, I shall order men to death." "Well, in our circumstances we want rigor." George yielded, and did his best. He laid siege to Belgrade; his lieutenants took several strongholds of the janizaries. Sultan Selim, who was pleased with these victories over the seditious janizaries, ordered Bekir Pasha of Bosnia to aid the Servians. The janizaries were unable to resist the double attack; their chiefs took to flight, but were overtaken and beheaded. But instead of returning to their peaceful occupations, the Servians, emboldened by their success, continued in arms, sent a deputation to Alexander, the emperor of Russia, and, on his promise to support their claims, another deputation to Constantinople, asking that all the strongholds of the country should be surrendered to them, and a compensation paid for the losses they had suffered. George in the meanwhile attacked and took the last strongholds of the janizaries in the southern part of the country. These proceedings irritated the sultan; he ordered Hafiz, the pasha of Nissa, to march to Servia and disarm the insurgents; but being resisted by George, at the head of 10,000 men, the pasha speedily retired. In the spring of 1806 Servia was invaded by Bekir Pasha from the west, and by Ibrahim, pasha of Scutari, from the south. Thus pressed, George first strengthened his precarious position by the massacre of suspected national leaders, marched against the Bosnians, routed them, and then turned against Ibrahim, who had been checked in his course by one of his lieutenants, and was now ready for a cessation of hostilities. This was approved of by the sultan, who terminated the negotiations of peace by granting the Servians the national independence of their country under the suzerainty of the Porte, with the obligation to pay an annual tribute. But the execution of the stipulations still had to be enforced; Belgrade, Szabacz, and other places, were to be taken by assault, and these conquests were stained by wanton massacres of Mohammedans. In the summer of 1807 the Servians became masters of the whole of their country. George was elected its chief, and as such acknowledged by the Porte; but he had to struggle against the independent spirit of the military chiefs, and the opposition of the senate, many members of which leaned toward Russia, while he disliked that power. He overcame the difficulties by energy and rigor, which had the merit of being impartial. His only brother, having committed an outrage on a girl, was hanged, and his mother forbidden to mourn for him. This illustrates the character of this barbarous hero, of whom a tradition relates that in his youth, when he first determined to leave the country of his oppressors, he shot down his father, who refused to follow him. Generally he was gloomy and taciturn, but wine made him talk and even dance. He was simple in his habits; his dress was like that of other peasants; he himself performed the hardest labors of a husbandman, and his daughter, like other peasant girls, brought water from the well. But cruelty and avarice stained both his life and administration. In 1809 the war of Alexander against Turkey seemed to George a favorable opportunity for extending the limits of his country and reconquering its ancient possessions and power. Crossing the south-western mountains to unite with the Montenegrins, he laid siege to Novibazar, and then made an attempt to conquer the Herzegovina, when he was surprised by the rout of his lieutenants by an invading Turkish army. The intervention of a Russian corps alone saved Servia, but in the following year George was again successful, and repeated victories also secured for him an almost absolute power, which easily crushed every opposition. The divan now offered him propositions of peace, which he rejected, generously refusing to treat without his Russian allies; but Russia, threatened in its existence by Napoleon, hastened to conclude the treaty of Bucharest (1812), whose stipulations in behalf of Servia proved illusory. Thus suddenly deserted, George lost his wonted energy, sought for peace instead of preparing for a vigorous resistance, and made humiliating proposals. Even these were rejected, and the Turkish army entered Servia in June, 1813. Veliko, the Achilles of Servia, who tried to check their march, was killed by a cannon ball, and on Oct. 2 George allowed the Turks to cross the Morava before his eyes. Eager to save his life and treasures, he fled the next day beyond the Danube, and sought refuge in Semlin, and subsequently in Chocim in Bessarabia. The deserted Servian troops disbanded, and the Turks were again masters of Servia, which but slowly recovered a partial independence under the lead of Milosh Obrenovitch. In 1817, when the Greek Hetairia was secretly preparing a general insurrection in the northern provinces of the Ottoman empire, George was tempted to leave his retreat, and to return in secret to Servia. Having succeeded in reëntering it undetected, he repaired to the house of Vuitza, one of his ancient lieutenants, whence he besought Milosh to raise the banner of insurrection. But the new national ruler, cautious and afraid of a rival, informed the pasha of Belgrade of his presence, and that official demanded his head. The demand was complied with, Vuitza surrendered him, and the head of the man

who had so often made the Mussulmans tremble was sent to Constantinople, where it was exposed at the gate of the seraglio. But the memory of the deliverer remained dear to his nation, and after the revolution of 1842, which overthrew the house of Obrenovitch, his son Alexander, called Karageorgevitch, was elected prince of Servia. This prince, however, was deposed, after a reign of 16 years, by the Servian national convention in Dec. 1858, and Milosh Obrenovitch invited once more to undertake the government.

CZERNY, Karl, a German composer, born in Vienna, Feb. 21, 1791, died there, July 15, 1857. He received his musical instruction from his father, a teacher of the piano, appeared at the age of 9 in a concert, and became acquainted with Beethoven and afterward with Clementi. He pursued the profession of his father from 1805 to 1835, and visited London in 1836. Among his pupils are Liszt, Döhler, and other distinguished artists. He wrote an immense number of compositions, and several theoretical works, of which the "Practical School of Composition" (3 parts, London and Bonn, 1849), and the "Sketch of the History of Music" (Mentz, 1851), are the most remarkable.

CZUCZOR, Gergely, a Hungarian author, born Dec. 17, 1800, at Andód, in the county of Neutra. From 1825 to 1835 he was professor at the colleges of Raab and Comorn, an appointment conferred upon him by the Benedictine monks, of whose order he was a member; but after he had removed to Pesth, where in 1835 he was elected assistant librarian and keeper of the archives of the Hungarian academy, the monks found fault with the worldly character of some of his poetical writings, and he was compelled to relinquish his office and his public literary pursuits, and to become again an inmate of the monastery. In 1844 he became the editor of the academical dictionary, in which he had advanced to the letter I when the work was interrupted by the revolution of 1848. Czuczor embraced the popular movement with enthusiastic zeal, and became one of its martyrs, being sentenced in 1849 by the Austrians to 6 years' imprisonment, for his *Riadó*, a Hungarian Marseillaise. The president of the academy, Count Joseph Teleky, caused the irons with which he had been manacled to be taken off, and enabled him to resume his labors on the dictionary. After the capture of Buda, he was released from prison by the Hungarian army; but on the defeat of the revolution he preferred prison to exile, and gave himself up to the victors. He was transferred to the state prison of Kufstein, where he remained incarcerated until 1850, when he was pardoned. While at Kufstein, he devoted himself to his lexicographical labors and to a translation of Tacitus into Hungarian. His epical poems, the "Battle of Augsburg," the "Assembly of Arad," and "Hunyady," are among his most renowned productions. He has also published a translation of Sparks's "Life of Washington."

D

D, the 4th letter in the Phœnician system of writing, and in most of those derived from it, is the representative of the last of the 4 classes into which the sounds of human speech may be divided—A representing the 1st or faucal (vocal) class, B the 2d or labial, and C the 3d or guttural. The letters of this 4th, denti-lingual or lingui-dental class, viz., *d*, *t*, *s*, *z*, *l*, *r*, being visible signs of the articulated sounds produced by various movements of the tongue touching the teeth and gums, are, therefore, convertible into each other. And whereas, in consequence of the misunderstanding of the real character of human phonetism, and of its graphic representation, letters have been misapplied to sounds, the combination *th*, and even *g*, *j*, *ch*, have been and are used instead of the letters of the 4th class. D is the sonorous counterpart of T, and is produced by applying the tip of the tongue to the superior incisive teeth and to their gum, while the tongue, obliquely rising, obstructs the passage of the breath; then by suddenly withdrawing this obstruction, while the larynx resounds (oscillates) during the passage of the air through the glottis, the sound in question is exploded. When the larynx does not thus resound, we utter the harder T. The *l*, *r*, are strictly lingui-dental, and *d*, *t*, *s*, *z*, denti-lingual. The Hebrew name *daleth* (whence the Greek *delta*), signifying door, gate, has nothing to do either with the nature of the sound or with the figure of the letter, being merely used on account of its beginning with this sound. The figure of the letter is more or less triangular, and more or less rounded, while in many so-called alphabets it is a mere angle or crook. In Slavonic it occupies (erroneously) the 5th place, in Ethiopic the 19th, or counting the Amharic additions, the 24th. Its hieroglyphs are the segment of a circle, an open hand, a beetle, which designate both T and D. Moreau de Dammartin derives the figure from the northern triangle, and from the little triangle in the head of the ram in the zodiac. In Arabic there are 4 modifications of it, to wit: *dal* (4, as a numeral sign), the 8th letter; *dzal* (700), the 9th; *dhad* (800), the 15th; and *dha* (900), the 17th; but in Cufic writing only the first is used. The Dēvanāgari has two series of letters, each consisting of 5 (*t*, *th*, *d*, *dh*, *n*), one of which is named cerebral or lingual, and the other dental; most of the modes of writing employed in the middle and south of Asia follow this arrangement. In Mongolic and Man-

tchooric D is distinguished from T by a dot, as it is also in the runes. The Finns, Lapps, and other northern people, scarcely distinguish it from T. It is the only sonorous consonant with the Hurons, and was very prevalent among the natives of the Mexican plateau and in the Quichua of South America. It does not occur on Etruscan monuments, T being used in its place. Grimm exhibits the convertibility of the lingui-dentals as follows:

Greek.	Gothic.	Old High German.
Δ	T	Z
Θ	D	T
T	Th	D

This scheme is illustrated in some of the following examples:

Gr. θυγατηρ, Goth. *dauhtar*, old Ger. *Tochtar*, Eng. daughter. Gr. οδους, Goth. *tunthus*, old Ger. *Zant*, Eng. tooth, &c. Latin: quo*d*annis and quo*t*annis; tend*o*, tensum; prehend*o*, prehensum. Euphonic: pro*d*es, ανδρες, French gen*d*re, &c., instead of pro-es, ανρες, gen-re, &c. Wallachian, zece, Lat. *d*ecem; zi, *d*ies; orz, hor*d*eum. Ital. *T*rapani, Lat. *D*repana. D is ejected from the following: Ital. *a*ombrare, Lat. *a*dumbrare; *P*o, Lat. Pa*d*us, &c.; Span. *o*ir, *c*aer, *c*reer, Lat. au*d*ire, ca*d*ere, cre*d*ere; so in the French, *ou*ïr, *Juif*, *sueur*, Lat. au*d*ire, Ju*d*æus, su*d*or. L substituted for D: cica*l*a, Lat. cica*d*a; Span. co*l*a, Lat. cau*d*a; Portug. ju*l*gar, Lat. ju*d*icare; U*l*ysses, Οδυσσευς; *l*acryma, δακρυ, &c. R substituted for D: me*r*idies for me*d*idies; a*r*mesariu for a*d*missarius (stallion). D is lost in the following: Ital. *d*, *piè*, Lat. ad, pede, &c.; Span. *fé*, Lat. fides; *crú*, Lat. crudus. Ger. *Th*eil, *d*eal; gu*t*, goo*d*; Go*tt*, Go*d*; Blu*t*, blood, &c. Ital. dan*z*are, French dan*s*er, Ger. tan*z*en, Lat. ten*d*ere. Al*d*obrando, Ger. Al*t*-brandt; *T*ancredo, *D*ankrath, &c. Eng. *t*en, *t*ooth, *t*oken; Lat. *d*ecem, *d*ens, *d*ocumentum; Ger. *z*ehn, *z*ahn, *z*eichen, &c. Ger. *d*ick, *th*ick; *d*ünn, *th*in; *D*aum, *th*umb; *d*er, *d*ie, *d*as, *th*e. Lat. participle passive, *-a*tum, *-i*tum; Eng. *-ed*; Span. *-a*do, *-i*do, &c.

—D began to be used as a numeral sign for 500 about A. D. 1500, when the Dutch printers employed the IↃ in the ancient CIↃ (M), 1,000, combining those signs in the figure of D. D was used by the Romans in the following abbreviations: D. for Decius, Dominus, Divus, Deus, Dictator, Dacia, Digestum, &c.; D. D. for Decemvirorum decreto; D. D. D. for Decemvirorum decreto datum, also for Dat, donat, dedicat; d. for die, dabam (I wrote), &c.; D. M., Diis manibus; D. O. M., Deo optimo maximo. With the Catholics D is the dominical letter when the 1st Sunday in January falls on the 4th.—On the reverse of European coins D indicates Lyons in France, Aurich and Düsseldorf in Prussia, Grätz in Austria.—D in music denotes the 2d interval of the present German and English diatonic scale, or the 3d string of the chromatic scale; this was the *re* of Guido Aretino, and is the *la* of the French.

DA CAPO, in music (abbreviated by the letters D. C.), an Italian phrase signifying from the beginning, which is placed at the end of a piece to direct the performer to return to the beginning, and repeat the first strain.

DAA, Ludwig Kristensen, a Norwegian politician, born Aug. 19, 1809, filled an important position in the Norwegian parliament, became one of the leaders of the democratic party, founded in 1848 the *Christiania Posten*, and has published a Swedish-Norwegian dictionary, and various other works. He is an enthusiastic admirer of American institutions.

DACCA, a district of the presidency of Bengal, in British India, between lat. 23° 12′ and 24° 17′ N., and long. 90° 11′ and 90° 58′ E.; area, 1,960 sq. m.; pop. 600,000. It is an almost entirely level country, traversed by numerous rivers, which abound with fish. Of wild animals, the district possesses the elephant, buffalo, tiger, bear, and leopard; of wild birds, the fishing eagle, vulture, kite, adjutant bird, and crane. The porpoise is seen in the large rivers, where the sharp-beaked crocodile and the blunt-beaked crocodile are also found. Snakes are numerous. The domestic animals are kine and buffaloes. The grain crops are not sufficient for the local consumption. Sugar, betel-nut, hemp, indigo, and other dyestuffs, are produced to some extent. The cotton product has considerably declined since the closing of the fine muslin manufactories at Dacca, and the attempts to introduce American cotton have not been successful, owing to the myriads of insects which destroy the bolls. The British authority was established consequent upon the grant of the dewanny, in 1765, but a small allowance continues to be made to the female connections and dependants of the last of the nawaubs of Dacca. In the N. part of Dacca are 2 distinct tribes, the Kunch and Rajbansi, more vigorous and daring than the rest of the population, which is about equally divided between Brahmins and Mussulmans; the latter, however, being considered more numerous. The projected line of the eastern Bengal railway intersects this district.—Dacca, the capital of the above described district, is situated on the Burha Gunga, an arm of the Brahmapootra, 150 m. N. E. from Calcutta, and 116 m. E. S. E. from Moorshedabad; pop. estimated at less than 70,000, of whom more than half are Mussulmans. It was once a considerable and wealthy city, being the centre of the manufacture of the famous fine muslins exported hence to all parts of the world. The operation of spinning the almost impalpable threads for these goods was carried on entirely by hand, and could only be done in the morning before the dew was off the ground, or over running water. Young women spun with their fingers and a fine steel spindle. The muslins, named from their fineness *abrawan*, or "flowing water," and *shabnam*, or "evening dew," were never imitated elsewhere, and were sold alone to princes and the very wealthy. With the decay of the Indian courts, the chief customers, the demand has ceased, and the manufacture has entirely stopped. Dacca exhibits at the present day little more than a vast expanse of ruins, extending for several miles along the river bank, and in many places overgrown with dense jungle, infested with snakes and wild beasts. The streets of the inhabited part are narrow and winding; the houses of the wealthier classes are built of brick, but the bazaars and the cottages of the poor are only thatched. The extensive citadel, situated on the western side of the town, and the magnificent palace built by Aurungzebe's grandson, Azim Ushaun, toward the close of the 17th century, are both in ruins.

The city and suburbs are stated to possess 10 bridges, 13 landing places (ghats), 7 ferry stations, 12 bazaars, 3 public wells, a variety of buildings for fiscal and judicial purposes, a gaol and gaol hospital, a lunatic asylum, an Indian hospital, an elephant depot generally containing 200 to 300 elephants, 180 Mussulman mosques, 119 Brahminical temples, Anglican, Greek, Armenian, Catholic, and Baptist churches. The latter denomination maintains a missionary establishment and a number of schools. There is a college managed by a local committee, but under the control of the government. About $60,000 was paid over to the city in 1850, as a bequest of Mr. Robert Mitford, for the benefit of the poor native inhabitants. The climate here is not so hot as in other parts of India, owing to its being situated in a low, moist, and verdurous region of country. The unhealthy season is from Aug. 20 to Oct. 10. During the rest of the year the city and vicinity are salubrious. The military, however, stationed in the vicinity of the city, were removed in 1852, owing to the unhealthiness of the locality; but in 1857 there were 2 companies of the 73d regiment Bengal native infantry here, whom the authorities, on hearing of the rising at Chittagong, Nov. 18, resolved to disarm. This was not effected without bloodshed. The Sepoys held some pieces of artillery, and a sharp contest took place at the barracks, from which they were finally driven out with loss by a few volunteers and 100 English sailors. The mutineers, after plundering several villages, hastened to Jelpigoree, the head-quarters of their regiment, where they were routed by their own comrades, and driven off to perish miserably in Bhotan.

DACCA JELALPOOR. See Fureedpoor.

DACE, a name applied to several native and foreign cyprinoid fishes, belonging principally to the genus *leuciscus* (Klein), which, as far as the North American species are concerned, has been subdivided into the genera *argyreus* (Heckel), *leucosomus* (Heckel), *plargyrus* (Rafinesque), *Richardsonius* (Girard), *luxilus* (Raf.), *semotilus* (Raf.), *mylocheilus* (Agass.), *algansea* (Gir.), *hybognathus* (Agass.), *ptychocheilus* (Agass.), *Hudsonius* (Gir.), *hybopsis* (Agass.), *clinostomus* (Gir.), *ceratichthys* (Baird), and *chondrostoma* (Agass.). From this long array of new genera, it is evident that it will be impossible in this article to give any thing like a satisfactory account of the numerous species popularly called dace. For full particulars, the reader is referred to the "Proceedings of the Academy of Natural Sciences, Philadelphia," vol. viii. p. 165, Sept. 1856. The true *leucisci* are far more numerous in the old world than in the new. As a species of this genus may be mentioned the orange dace (*L. croceus*, Storer), about 3½ inches long, of a greenish color, with the throat flesh-colored, an indistinct brown band on the side running longitudinally with a small black blotch at the end, and the fins orange; from Alabama. These genera belong to the malacopterygian or soft-rayed fishes; the mouth is slightly cleft, the jaws weak and without teeth, and the pharyngeal bones toothed; the body scaly, one dorsal fin, and no adipose dorsal; sometimes with barbels on the head. The name of shiner is also given to many of the species called dace. The roach dace, or silvery dace (*leucosomus pulchellus*, Storer), is among the largest species, being sometimes 14 inches in length; the color is dark brown above, the upper portion of sides brassy green, lower portion and abdomen flesh color, with golden reflections; the head is black above, with the gill covers coppery, the upper jaw slightly the longer. It delights in eddies and pools, and is found from New York to Nova Scotia. It is synonymous with *cheilonemus* (Bd.), and has 5 described species; there is a small barbel upon the maxillary, near the angle of the mouth. The black-nosed dace (*argyreus atronasus*, Mitch.) rarely exceeds 3 inches in length, is found in the rivers of Massachusetts and New York, and is often called brook minnow. It is reddish brown above, abdomen silvery white, with minute brown blotches, a dark band passing from the nose to the tail. The natural characters of the genus are a snout more or less protruding beyond the lower jaw, with a small barbel at the angle of the mouth; it is synonymous with *rhinichthys* (Agass.). The long-nosed dace (*A. nasutus*, Ayres) is about 4 inches long, inhabiting rapid northern streams; it is dark brown above, white below, with the dorsal and caudal fins brownish. The smaller specimens of the last 2 species make excellent bait for large trout. Seven other species are described. The red dace (*plargyrus cornutus*, Mitch.), one of the prettiest of the American cyprinoids, is about 5 inches long, blackish brown above, with metallic reflections, sides brilliant and cupreous, all the fins and opercles margined with crimson; the jaws are equal, and there are no barbels on the head; the scales are very large and imbricated. This is a very active fish, is common in streams frequented by brook trout, and is frequently taken by fly-fishers for the latter species; it is often eaten in the British provinces, and is in the best condition in May. This genus is synonymous with *hypsolepis* (Bd.), and contains 6 other described species. The golden and flat dace belong to the genus *luxilus* (Raf.), and species *L. Americanus* (Lacép.), and *L. compressus* (Raf.); 5 other species are described; no barbels on the head. The lake dace is *semotilus atromaculatus* (Mitch.), about 10 inches long; 4 other species are described. The north-west dace is *mylocheilus caurinus* (Rich.), about a foot long, discovered in the Columbia river; it has a maxillary barbel; there are 2 other species. The Columbia river dace is *ptychocheilus Oregonensis* (Rich.); it is more than a foot long, brownish above, silvery white below; there are 4 other species. The shining dace of Lake Champlain is *hybognathus nitidus* (De Kay), only 2 inches long; there are 4 other species. Storer's dace, a western species, about 8 inches long, is *hybopsis Storerianus* (Kirtland); there is also a southern

species (*H. Winchelli*, Gir.). The common dace of Europe is the *leuciscus vulgaris* (Cuv.), inhabiting the deep and still water of the streams of Great Britain, France, Germany, and Italy; it rarely exceeds 10 inches in length; the prevailing color is dusky blue above, becoming paler on the sides, and white on the abdomen; cheeks silvery; dorsal and caudal fins pale brown; the other fins nearly white, tinged with pale red. They are gregarious, swimming in shoals, and spawning in June; they feed on worms and insects, but, like the trout, will rise at an artificial fly. The flesh is not much esteemed as food, and it is principally used as a bait for pike-trolling, on account of its silvery brightness. The shining scales of the roach and other dace are employed in the manufacture of artificial pearls, being attached to the inner surface of the transparent shell.

DACIA, a province of the Roman empire, bounded N. by the Carpathian mountains, which separated it from Sarmatia, S. by the Danube (Ister, Danubius), which separated it from Mœsia, E. by the Pruth (Hierasus) and the Euxine, and W. by the Theiss (Tibiscus, Tysia). It thus comprised a part of Hungary, with the banat of Temesvár, Transylvania, Wallachia, and Moldavia. According to some it included N. E. the Bukovina, and E. Bessarabia. Before the Roman conquest, which was the last aggrandizement of the empire in Europe, this country was the habitation of the Daci, a brave people, probably of Thracian race, called by historians the most warlike of men, and, according to some, identical with the Getæ, who at the time of Darius's Scythian expedition lived between the Balkan and the Danube. Strabo speaks of the Getæ as living in the E., and of the Daci as living in the W. part of the country. In the reign of Augustus they crossed the Danube, plundered the allies of the Romans, and spread terror even among the latter, but were finally driven back into their own country. Under their king Decebalus they compelled Domitian, after a protracted struggle, to purchase an ignominious peace by an annual tribute. The emperor, however, decorated himself with the title of Dacicus. Trajan refused to pay the tribute, and renewed the war. Decebalus proved himself a rival not unworthy of this emperor, and ended the struggle with his life (A. D. 106), only after having exhausted every resource both of valor and policy. The new province was colonized by inhabitants from all parts of the empire, with whom the Romanic language of the modern Wallachians, both in Transylvania and the Danubian principalities, originated. Notwithstanding the resolution of the successors of Trajan to contract the limits of the empire, Dacia still remained one of its provinces. In the 3d century it was invaded by the Goths, and resigned to them by the emperor Aurelian, who removed the Roman inhabitants to Mœsia, giving the name of Dacia to that part of the latter province in which they settled.

DACIER, Anne (Lefèvre), a learned French woman, born in Saumur in March, 1654, died Aug. 17, 1720. She was the daughter of the distinguished scholar Tanneguy Lefèvre, and acquired her first instruction from overhearing the lessons given by her father to his son. Lefèvre, amazed at the extent of the information she had thus acquired, devoted every care to her education, and at his death, in 1672, she was one of the most accomplished scholars in Europe. In that year she went to reside in Paris, where in 1674 she published an edition of Callimachus. The reputation acquired by this work procured her an invitation to assist in editing the celebrated classical series *Ad usum Delphini*, ordered by Louis XIV. for the use of the dauphin. In the discharge of this duty she prepared editions of Florus, Eutropius, Aurelius Victor, Dictys Cretensis, and Dares Phrygius. In 1683 she was married to André Dacier, a man of learning not inferior to her own, and a favorite scholar of her father, under whose instruction they had for many years been fellow pupils. This union was called "the marriage of Greek and Latin." Two years afterward they both abjured Protestantism, and received from the king a pension of 2,000 livres. Madame Dacier thenceforth devoted herself no less assiduously to literary pursuits, and during the remainder of her life produced translations of several plays of Plautus, the whole of Terence, the Iliad and Odyssey of Homer, the "Plutus" and "Clouds" of Aristophanes, and the whole of Anacreon and Sappho. The translations from Homer involved her in a literary war with M. de la Motte and others, concerning the comparative merits of ancient and modern literature, which she conducted with ability and enthusiasm, if occasionally with warmth. She also assisted her husband in the translation of Marcus Antoninus and Plutarch's "Lives." She was distinguished for modesty and amiability, and amid her engrossing literary avocations neglected no domestic or maternal duties.—M. Dacier, born at Castres in 1651, was equally industrious as an editor and translator of classical authors. Among the works translated by him, in addition to those mentioned, were Aristotle's "Poetics," the "Œdipus" and "Electra" of Sophocles, the works of Hippocrates and Horace, and some of Plato's dialogues. He was one of the scholars engaged in preparing the Delphin editions of the classics, and his only contribution to it was an edition of Pomponius Festus and Valerius Flaccus. He was keeper of the library of the Louvre, and a member of the French academy. He died 2 years after his wife, whose death left him almost inconsolable.

DACOTAH, or Dakota, a territory of the United States, lying between lat. 42° 30′ and 49° N., long. 96° 30′ and 103° W., bounded N. by British America, E. by the states of Minnesota and Iowa, S. and W. by Nebraska; length from N. to S. about 450 m., average breadth about 200 m.; area, 70,000 sq. m.; pop. in 1858 estimated at 10,000, exclusive of Indians, but including about 4,000 half-breed settlers, who live chiefly by the

chase. The latter occupy a number of trading stations along the Missouri river in the S. and S. W. parts of the territory, and in the valley of Red river, near the British frontier. The Indians belong to the Yankton, Sissiton, Dacotah or Medawakantwan (Sioux), and Wahpetonwan (Sioux) tribes, many of whom receive an annuity from the U. S. government, but the efforts made to improve their condition have thus far had little effect. In 1858 delegations from these tribes met in Washington, and ceded to the government valuable agricultural lands on the Sioux, Missouri, and Red rivers. The white settlements are almost exclusively in the south-east, on the Minnesota border. The surface of the territory is elevated, but not mountainous. A plateau called the *coteau des prairies*, or "prairie heights," with an average elevation of 1,450 feet above the sea and a breadth of 15 or 20 m., runs for 200 m. near its E. boundary, while a similar table-land, of less height, occupies the middle and N. portions. The basin of Red river, in the north-east, is covered with open grassy plains, and the south-west presents high rolling prairies. The face of the country is moreover pleasantly diversified with a vast number of lakes and ponds, affording a constant supply of good water. The largest of these are lakes Tchanchincanah, Poinsett, Abert, Preston, Traverse, and White Wood, beside Benton and Big Stone, which lie partly in Minnesota. In the N. part is a large expanse of salt water, 40 m. long and 12 m. in maximum breadth, called Minni Wakan, or Devil lake, of which no outlet has yet been discovered. More than half of the frontier of Dacotah is bounded by large rivers. The Missouri after receiving the White Earth separates it from Nebraska, and at the S. E. extremity of the territory is joined by the Big Sioux, dividing it from Iowa. The N. half of the Minnesota line is formed by the Bois des Sioux and the Red river of the North, the latter of which flows into British America. These streams receive innumerable smaller rivers, the chief affluents being, of the Missouri, the Yankton, East Medicine Knoll, Wananri, Tchan-sansan or Rivière à Jacques, Vermilion; and of the Red river, the Bois des Sioux, Wild Rice, Shayuen, Maple, Rush, Goose, Turtle, Buffalo, and Pembina. The Tchan-sansan (also called the James or Dacotah) rises near Devil lake and flows almost due S. through the middle of the territory, receiving numerous tributaries. The Mouse river enters from British America, and, after a long sweep through the N. W. part, recrosses the frontier. The climate of the south is mild and healthy, but that of the north is very severe. At Pembina, near the 49th parallel, the cold is sometimes so intense as to freeze quicksilver, and according to observations made there in 1847, the mean temperature of the month of January was 12½° below zero, the lowest 48° below, and the highest 30° above zero. The mean temperature of June and July was 69°, and the highest 96°. The soil of the S. and S. E. parts is said to be excellent, and the valleys of the Red, Missouri, and other rivers are highly productive, yielding Indian corn, oats, wheat, tobacco, the sugar cane, and nearly every kind of kitchen vegetable. Much of the land is well timbered. Coal is said to abound on Big Sioux river, fine building stone, limestone, and good clay for brick making are found in the south, and the north contains rich deposits of salt. There are good roads from Sioux City, at the mouth of the Big Sioux, as far N. as Medary, on the same stream, a distance of 180 miles, where they meet the great Pacific wagon road which crosses the territory, and from which other roads diverge in many directions. The unexplored parts of Dacotah are the hunting ground of the Indians, and are still ranged by vast herds of buffalo, elk, deer, and antelope; the black bear, wolverine, muskrat, otter, mink, marten, and wolf are found in large numbers; the grisly bear and moose are occasionally met with, and the fur trade is prosecuted by the half-breeds of the north more extensively than in almost any other part of the United States. Dacotah formed part of the territory of Minnesota, from which it was separated on the erection of the latter into a state, May 11, 1858. The inhabitants elected a legislative assembly, which met at Sioux Falls in Oct. 1858, adopted a code of laws, divided the territory into counties, and applied to congress for its formal organization.

DACOTAH, a S. E. co. of Minnesota, bounded N. by the Mississippi, N. W. by St. Peter's or Minnesota river, and S. E. by the Cannon; area, 550 sq. m.; pop. in 1857, 8,158. The surface is nearly level and the soil fertile. Indian corn, wheat, oats, and grass are the staples. Capital, Mendota.

DACTYL, in prosody, a metrical foot composed of one long and two short syllables; thus, *tĕmpŏrā*. It was esteemed by the Greeks the most ancient of all the poetical feet, and its origin was ascribed to Bacchus, who was said, anterior to Apollo, to have recited the oracles of Delphi in verses of this measure. It enters into the composition of the noblest verses, as hexameters, pentameters, and alcaics.

DACTYLOLOGY, the art of communicating with others by spelling words with the fingers. By whom or at what period this method of conversation was first devised is uncertain. The first manual alphabet of which we can find any account was published by J. P. Bonet in 1620, in his "Reduction of Letters and Arts, for the Purpose of Teaching the Dumb to Speak." Of this he claimed to be the inventor. It was the basis of the single-handed alphabet now in general use in this country and France, though it has been somewhat modified. The idea of this alphabet is the formation of figures resembling the several letters by the position of the fingers of the right hand. In 1680 George Dalgarno, of Oxford, Eng., published his *Didascalocophus*, in which he gave a drawing of a manual alphabet invented by himself requiring the use of both hands. The design of this was to

designate the different letters, not by their form, but by their position on the ends and joints of the fingers and the hand; thus, the vowels were designated by touching the ends of the thumb and fingers of the left hand with the fore finger of the right; B, C, D, F, and G, by touching the 1st joint of the thumb and fingers; H, K, L, M, N, the 2d joint; P, Q, R, S, the 3d joint of the fingers; T, V, W, the 3 prominences of the inside of the hand immediately below the fingers; and X and Z, the base of the thumb and hand. All the consonants were designated by touching their location with the thumb of the other hand. This, with some modifications, is the alphabet in use among deaf mutes in England. Numerals are also designated by the fingers. The 10 digits undoubtedly formed the first abacus, but for purposes of convenience it is preferable to be able to designate all the numbers by one hand only. Mr. Stansbury, the first principal of the New York institution for the deaf and dumb, invented a method of designating numbers, which is in general use in European institutions. It is as follows: the thumb free with the hand closed denotes 1, the thumb and forefinger 2, and so on to 5; 6 is designated by the little finger being extended with the remainder of the hand closed; 7, the little finger and ring finger; 8, the little, ring, and middle finger extended; 9, the 4 fingers extended and the thumb closed; 10, the whole hand closed. For tens, the position of the hand is changed from perpendicular to horizontal; for hundreds, the hand is pointed downward; for thousands, the left hand is placed across the body toward the right shoulder, and each sign has then the value of thousands; tens of thousands and hundreds of thousands are designated in the same way as tens and hundreds; by changing to the left shoulder millions, tens of millions, and hundreds of millions may be designated. This system has been modified in American institutions by designating 6 by touching the thumb to the little finger; 7, by touching it to the ring finger; 8, to the middle finger; 9, to the fore finger; and 10, by placing the closed hand horizontally with the thumb extended and making a slight backward motion of the hand. De Gerando, in his work on the education of deaf mutes, says with truth that dactylology is to alphabetical writing what the latter is to speech. Formed upon writing as its model, it represents it precisely as writing represents words. It is a valuable means of communication with deaf mutes, and although less rapid than speech and possessing none of those qualities of the voice by which we judge so much of the person speaking, it yet serves to convey the ideas of those who but for its aid might often be desolate even in the midst of a crowd. It affords the means of communication between the deaf and dumb and the blind, as well as between deaf and dumb persons in darkness. It should not be confounded with the natural language of signs used by the deaf and dumb. The latter is not, and, in the nature of the case, never can be used, except for expressing words or ideas; the manual alphabet only designates letters, or, at most, syllables. Syllabic dactylology has been used by several teachers, but is attended with many difficulties. Péreire invented a system which he used with great success, but it perished with his papers. Several attempts have been made to introduce it within a few years past, and plans have been presented for adoption; but at the meeting of the convention of teachers of the deaf and dumb at Staunton, Va., in 1856, the committee appointed to report upon them were unanimous in the opinion that they were impracticable.

DADE, the name of counties in several of the United States. I. A N. W. co. of Ga., bordering on Tenn. and Ala.; area, 160 sq. m.; pop. in 1852, 2,527, of whom 182 were slaves. It occupies Lookout valley, and is encompassed by mountains of considerable height. Iron, coal, and other minerals are found in various parts of the county. The productions in 1850 were 147,849 bushels of corn, 17,965 of wheat, and 15 bales of cotton. There were 15 churches, 2 flour mills, 2 saw mills, and 1 iron forge. Value of real estate in 1856, $375,510. Named in honor of Major Francis Langhorne Dade, who was killed in the Florida war, in December, 1835. Capital, Trenton. II. A S. co. of Florida, bordering on the Atlantic; area, about 1,000 sq. m.; pop. 150. The surface is low, level, and almost wholly occupied by the Everglades, a vast expanse of shallow water, dotted over with innumerable small islands. Proposals have been made to drain these portions of the county by means of canals. During the rainy season they are quite impassable. The county has one good harbor for vessels drawing 9 feet of water, and on Cape Florida, at the entrance to this harbor, is a lighthouse. Indian Key is the principal village. III. A S. W. co. of Mo., with a diversified surface and a productive soil; area, 498 sq. m.; pop. in 1856, 6,061, of whom 267 were slaves. In 1850 it yielded 325,958 bushels of corn, 11,371 of wheat, 105,545 of oats, and 588 tons of hay. Sac river, a tributary of the Osage, is the principal stream. There were 4 grist mills, 5 saw mills, and 223 pupils attending public schools. Capital, Greenfield.

DÆDALUS, a mythical personage, under whose name the ancient Greek writers are supposed to have personified an early period of the development of the arts of sculpture and architecture, or their introduction from Egypt. He is generally represented as an Athenian of the royal house of Erechtheus, though, from his long sojourn in Crete, he is also called a Cretan. Having become a great sculptor, he instructed in his art Calos, Talus, or Perdix, his sister's son, but afterward killed him through envy, when he saw the skill of his disciple surpassing his own. Condemned to death by the areopagus, he fled to Crete, where he gained the friendship of Minos, but having constructed the wooden cow for Pasiphaë, and the labyrinth of Cnossus, in which the Minotaur, the monster

to whom she gave birth, was kept, he attracted the revenge of the king, and was imprisoned. He was released by Pasiphaë, and finding no vessel to escape from the island, as Minos had seized all those which were on the coast, he procured wings for himself and his son Icarus, which were fastened on with wax. He took his flight over the Ægæan, and arrived safely in Sicily; but Icarus flying too near the sun caused the wax on his wings to be melted, dropped down, and perished in that part of the sea which, after him, is called the Icarian. According to some, Dædalus on his flight alighted at Cumæ in Italy, where he erected a temple to Apollo, dedicating to that divinity the wings which had saved him. When Minos knew his place of refuge, he sailed with a fleet to Sicily, where he was treacherously murdered by Cocalus, king of the Sicani, who protected the fugitive; or according to others, he was protected by the daughters of that king. Several works of art in Greece, Italy, Libya, and the islands were attributed to Dædalus, as well as the invention of several tools belonging to his art. The Greeks gave the name of *Dædala* to certain ornamented wooden statues or images of their gods.

DAENDELS, Herman Willem, a Dutch general, born at Hattem in 1762, died in Guinea, on the coast of Africa, in June, 1818. During the troubles which convulsed the United Provinces in 1787 he favored the party of the patriots, and was obliged by the momentary triumph of the Orangists to take refuge with many of his political friends in France. He devoted himself for a while to commercial enterprises in the city of Dunkirk, but became commander of a corps of volunteers in the wars of the French revolution, and rendered important services to Dumouriez in his expedition against the Netherlands. In 1794, having assisted Pichegru in taking possession of all Holland and in causing the flight of the Orange family, he entered into the service of the Batavian republic. In 1799 he commanded one of the divisions of the Batavian army, and, in conjunction with Gen. Brione, obliged the Anglo-Russian force, which had made a descent on the Dutch coast, to capitulate. In 1803 he resigned; but in 1806 he offered his services to the king of Holland, and was restored to his former rank. He was soon after made a marshal, and appointed governor-general of the Dutch possessions in the East Indies. He resided upon the island of Java for 3 years, devoted his attention particularly to the cultivation of coffee, and gave an account of his administration in a work full of valuable information as to the statistics and moral state of the island. After his return from the Indies he served in the Russian campaign of 1812, and as governor of Modlin in Poland. He was next appointed to take possession of the provinces of Guinea, which had been restored to Holland, and to organize their administration. He entered with energy upon this duty, conciliated the neighboring negro states, favored the establishment of new colonies, and mitigated as far as he was able the treatment of the slaves. He died in the midst of these labors.

DAFFODIL, the old English name given to the *narcissus pseudonarcissus* and its allies, popular garden flowers, commonly known as bulbous roots. The hardiest as well as earliest of the daffodils is the *N. pseudonarcissus* (*flore pleno*), whose double, yellow, and conspicuous blossoms visit us as soon as the snow leaves the ground. Later the poetic narcissus or white daffodil, both the single and double kinds, add to the charms of spring and breathe forth a pleasant and inviting odor. Several beautiful kinds are largely cultivated, some of which are styled polyanthuses, from the many-stalked blossoms, white or yellow, crowning the scape or flower stem. The bulbs are imported from Holland, and are generally hardy.

DAGGETT, David, LL.D., an American lawyer and judge, born at Attleborough, Mass., Dec. 31, 1764, died at New Haven, Conn., April 12, 1851. He was graduated at Yale college, with high honor, in 1783; was admitted to the bar in New Haven in 1786; was chosen representative to the legislature in 1791; speaker, in 1794; and was a member of the council, or upper house, from 1797 to 1804, and again from 1809 to 1813. In 1811 he was appointed state's attorney for New Haven county, and in 1813 was chosen to the U. S. senate, where he continued till 1819, when he returned to his extensive practice at the bar in his adopted state. In 1824 he became instructor in the law school in New Haven; in 1826 was appointed Kent professor of law in Yale college; and in the same year was chosen judge of the superior court, and received the degree of LL.D. from Yale college. In 1832 he was made chief justice of the supreme court of the state, retiring by limitation of age in 1834. Judge Daggett was a man of quick and thorough insight both into subjects and men; of well balanced judgment and strong common sense; of varied eloquence and great power as a speaker; thorough in his knowledge of law; of accurate and retentive memory; abounding in wit and humor; and commanding universal confidence by his abilities, judgment, and general character. As an advocate and counsellor, he has had few equals. In social life he was a model of dignified courtesy; and yet, by his sympathy alike with old and young, his cheerfulness, and his varied fund of anecdote and reminiscences of the past, was the life of every circle that he entered. A sketch of his life and character, by the Rev. Dr. Dutton, was published in 1851.

DAGGETT, Naphtali, D.D., an American clergyman, born at Attleborough, Mass., Sept. 8, 1727, died at New Haven, Conn., Nov. 25, 1780. He was graduated at Yale college in 1748; in 1751 was ordained pastor of a Presbyterian church in Smithtown, Long island; and in 1755 was chosen professor of divinity in Yale college, which office he held at his death. On

the resignation of President Clap, in 1766, he was chosen president *pro tempore*, and in this capacity officiated for more than a year. In 1774 he received the degree of D.D. from the college of New Jersey. He was a good classical scholar, well versed in moral philosophy, and a learned divine. He published several sermons; and also, in 1780, some account of the celebrated "dark day," which alarmed so many in New England with the fear that the day of judgment was at hand. In July, 1779, when the British attacked New Haven, Dr. Daggett, fowling piece in hand, went forth in gallant style to the fight, was taken prisoner, and compelled, in an intensely hot day, to act as guide to the advancing columns of the enemy, while they repeatedly pricked him with their bayonets when his strength failed. He never fully recovered from this treatment.

DAGH, a word in the Tartar languages signifying mountain; thus, Daghestan, land of mountains; Keshish-dagh, the modern name of Mt. Olympus.

DAGHESTAN, the country comprising all the E. slope of the Caucasus toward the Caspian sea, from the Terek river to the peninsula of Apsheron, between lat. 41° and 43° N.; area, 17,500 sq. m.; total pop. estimated at nearly 2,000,000. The Kasbek or Mquinvari mountain, 14,500 feet high, is about the western terminus, and also the highest point of the country. The mountains of original formation are extremely rugged, the climate in the higher regions severe, though the Kasbek is the only peak reaching to the line of eternal snow; the narrow valleys, deeply imbedded, are rather fertile, productive of grains, rice, millet, saffron, fruit, nuts, wine, and fine timber; the iron, lead, and sulphur mines are developed, but not beyond the purpose of supplying the necessities of war, and the weapons manufactured here are justly celebrated. Cattle are raised in large numbers, as well as excellent horses, asses, camels, and a species of fat-tailed sheep. Daghestan is the abode of the powerful tribe of the Lesghians (the Albani of antiquity), numbering about 400,000, chiefly Mohammedans of the Soofee sect. The Lesghians are still independent of Russia, to which their country nominally belongs. Further down in the hilly region live Tartar tribes of Mongol descent, called Kumyks, Nogaians, and Truchmenes (Turkomans), all of them Mohammedans, and more or less nomadic, living principally by the raising of cattle and horses. A few towns of some commercial importance are situated along the Caspian coast, which is flat, marshy, or sandy, and in many portions not well watered. The Kumyks are allies of the Lesghians against the Russians; the remainder are peaceable Russian subjects. The territory of Daghestan which constitutes the Russian province of that name comprises an area of only about 6,000 sq. m., and a population in 1851 of 479,042. It is divided into 4 districts. The great rising against the Russians in 1820 commenced with a campaign in Daghestan. (See CAUCASUS.)

DAGO, DAGÖE, or DAGDEN, an island belonging to Russia, in the Baltic sea, near the entrance of the gulf of Finland, opposite to the island of Oesel, from which it is separated by the Sele-Sund. Its greatest length is 37 m. and greatest breadth 15 m. It is comprehended in the province of Esthonia. The inhabitants are 10,000 in number, chiefly Swedes, and employed in husbandry, rearing cattle, and fishing. The soil is principally of sand or chalk, and unfertile, and the cattle are of an inferior stunted breed. Dago was held by the Danes prior to 1645, and by the Swedes from that time till 1791, when they ceded it to Russia.

DAGOBERT I., a Frankish king of the Merovingian line, born about 600, died at Épinay, Jan. 19, 638. The son of Clotaire II., he was, as early as 622, acknowledged king of Austrasia. On the death of his father in 628 he inherited Neustria and Burgundy, and 3 years later he reannexed to those kingdoms Aquitania, which had been inherited by his brother Charibert. He thus reigned over the whole of the Frankish dominion, and successfully opposed the encroachments of the Frankish lords, repelled an invasion of the Vascones, and forced the Bretons to acknowledge his supremacy. His court was renowned for a magnificence almost equal to that of Constantinople. He was liberal toward the church, and founded several monasteries which he richly endowed, including the abbey of St. Denis. The goldsmith Eligius, who was afterward canonized, was one of his ministers, and greatly contributed to the splendor of his reign. One of the king's most meritorious acts was the revision and publication of the old national statutes, known as the Salic and the Ripuarian laws. His fame is marred by an atrocious act of perfidy toward some Bulgarians who had sought refuge within the limits of his kingdom and who were slaughtered; and above all by his debauchery. "This Solomon of the Franks," an old chronicler says, "given up to extreme lewdness, entertained no less than 3 wives bearing the name of queens, and so many concubines that it would be too long to enumerate the same." He was buried at St. Denis.

DAGON (Heb. *dag*, fish), a Phœnician or Syrian divinity, who, according to the Bible, had richly adorned temples in several of the Philistine cities. The rulers of the Philistines offered to Dagon, at Gaza, a great sacrifice for having delivered Samson unto them; and the statue of Dagon at Ashdod fell to the ground, with its face downward, before the ark of the Lord. There is much uncertainty concerning the origin, attributes, and even the sex of this divinity, who has been identified by various commentators with Noah, Japheth, Saturn, Jupiter, Venus, Ceres, Isis, Oannes, Dirce, Astarte, and the whale Ceto. He was represented as a monster, whose upper part bore some resemblance to the human form, but terminated below in a fish. The different ancient traditions concerning him prove only that the origin of his worship was unknown; he seems, however,

to have been generally regarded as a symbol of fertility and reproduction.

DAGUERRE, Louis Jacques Mandé, inventor of the process, called after his name, by which images from the lens of a camera obscura are fixed upon metallic plates, born at Cormeille, department of Seine-et-Oise, France, in 1789, died at Petit-Brie-sur-Marne, July 12, 1851. He commenced his career in Paris as a scene painter, and rivalled the best of his contemporaries in the brilliancy and novelty of his effects. Having assisted M. Prévost in painting his panoramas of Rome, London, Naples, and other great cities, he conceived the idea of heightening the effect of such views by throwing colored lights and shadows upon them, so as to produce the various changes of the day and season. This invention, called the diorama, was perfected by Daguerre and Bouton in 1822, and for many years the former was busily employed in preparing pictures for exhibition in the buildings erected for that purpose in Paris and London. In 1839 he sustained a great loss by the burning of his establishment in Paris. Previous to this time he had been for many years experimenting, in connection with Niepce, on the method of obtaining permanent fac-simile copies of objects by the chemical action of the sun. After the death of the latter in 1833 he prosecuted his researches alone, and in 1838 succeeded in fixing upon prepared metallic plates distinct and indelible impressions of the images thrown upon them by the lens of the camera. The invention was announced at the session of the *académie des sciences*, in January, 1839, by Arago, and excited a profound interest, which was heightened by the exhibition soon after of a number of pictures taken by the new process, called by its inventor the *méthode Niepce perfectionnée*. He was subsequently made an officer of the legion of honor, and by a vote of the French chambers an annuity of 6,000 francs was bestowed upon him, on condition that his process should be made public. To the close of his life he continued to labor on the improvement of the daguerreotype, and has left 2 works on the theory and practice of the art. A monument has been erected to his memory by subscription. —The process invented by Daguerre, and its subsequent improvements, will be treated under the title Photography.

DAHL, Mikael, a Swedish portrait painter, born in Stockholm in 1656, died in London in 1743. In 1688 he repaired to London, where he was patronized by Queen Anne and the prince consort. At Hampton court are several of his portraits of admirals. His equestrian portrait of Charles IX. of Sweden is at Windsor, and some of his whole-length representations of ladies are at Petworth. He also painted a portrait of Lady Walpole, which is at Houghton.

DAHL, Vladimir Ivanovitch, a Russian author, of German origin, born in St. Petersburg about 1800, was educated there at the naval academy. In 1819 he joined the Russian fleet in the Black sea. Subsequently he practised as physician at Dorpat, and served in the expedition against Poland and against Khiva, in Turkestan. He collected more than 15,000 tales, fables, and proverbs, beside colloquial expressions current among the different tribes of the empire; and he was so much struck with the contrast between the language of the cultivated classes in the capital and that of the common people in the provinces, that he wrote a book for the purpose of pointing out this discrepancy and of advocating a reform. This work is entitled *Poltora slova o Ruskim yazikie* ("A Word or two about the Russian Language"). The result of his personal contact with the masses of the Russian people is palpable in his novels and tales. His heroes are not czars and grand duchesses, but serfs and common women. The style is simple, pure, and lively, and his novels, apart from the sentimental interest of the plot, abound with original descriptions of scenery, and of the manners of the people. He has published some of his volumes separately, and contributed others to periodicals under the *nom de plume* of Kosak Luganski. He is a homœopathic physician by profession.

DAHL, Johan Kristian Clausen, a Norwegian landscape painter, born Feb. 24, 1788, at Bergen, in Norway, died Oct. 14, 1857, in Dresden, in which city he had resided since 1818. In 1820–'21 he visited the Tyrol, Naples, and Rome, in company with Christian VIII. of Denmark, and in the latter city received many attentions from Thorwaldsen and other northern artists established there. From Italy he brought back the studies of his "View of Vietri—the Island of Capri," the "Eruption of Mount Vesuvius," and other striking pictures. But his most celebrated and characteristic works are those in which the grand and gloomy features of northern nature are portrayed. Of these the "Coast View," near Bergen, now in the possession of the king of Sweden, is considered the finest. The "Shipwreck," "Ancient Scandinavian Tombs and Monuments," the "Saxon Switzerland," the "Great Winter Landscape of Zealand, Prestöe, and Wordinborg," and others, also enjoy a great reputation. His works are to be found in all parts of Europe, and even in America.—His son, Siegwald Johannes, born in Dresden, Aug. 16, 1827, is devoted to genre painting and to the painting of portraits and animals.

DAHLBOM, Anders Gustaf, a Swedish entomologist, born in East Gothland, March 3, 1806. He was graduated at Lund in 1829, and officiated as teacher of natural history and as superintendent in the zoological museum of Lund from 1830 till 1842, when he was appointed assistant professor of entomology and keeper of the entomological museum of the university. Beside his contributions to the transactions of the Stockholm academy and to the scientific press, he published, from 1829 to 1852, 10 distinct works on insects in Latin and Swedish, of which his *Hymenoptera Europæa præcipue Borealia* is the most important.

DAHLGREN, Carl Johan, a popular Swedish poet, born June 2, 1791, died May 2, 1844, officiated as clergyman in various churches of Stockholm, and on several occasions as a member of the diet, where he advocated liberal principles. His complete works were published in Stockholm, in 6 vols. (1847–'49).

DAHLGREN, John A., commander in the U. S. navy, a native of Pennsylvania, entered the service as midshipman in Feb. 1826, was promoted to be a lieutenant, March, 1837, and a commander in Sept. 1855. Since 1847 he has been employed on ordnance duty, and, with the exception of a short cruise in command of the Plymouth sloop of war, armed according to his views with a few heavy shell guns, has been engaged in very important experiments at the navy yard at Washington, under the direction of the bureau of ordnance and hydrography. These experiments, together with other measures taken by that bureau, have resulted in great changes, as well as in increased system and efficiency, in that department of the naval service. Among these changes is the adoption of heavy shell guns of the Dahlgren pattern (see Cannon), and also of a very efficient armament for boats, consisting of bronze howitzers of 24 lbs. and 12 lbs. calibre, of light pattern, their projectiles being shells, shrapnel and canister shot. Light field carriages of iron, devised by Commander Dahlgren, are supplied with these howitzers, by which they are made available upon land. He has in the course of his experiments made the following publications, a part of them by order of the bureau of ordnance: "Report on the 32 pounders of 32 cwt." (1850); "System of Boat Armament in the U. S. Navy" (2 editions, 1852 and 1856); "Naval Percussion Locks and Primers" (1852); "Shells and Shell Guns" (1856).

DAHLIA, the numerous varieties of which are among the most popular of flowers, originated in Mexico from a single form known as *D. variabilis*. In a wild condition it is said to be about 7 or 8 feet high, with purple or lilac blossoms of no great merit. Thouin (*Annales du muséum*, vol. iii.) has given a memoir on the dahlia, making 3 species, viz.: *rosea*, *purpurea*, and *coccinea*. Simultaneous with the efforts of the Dutch florists, semi-double flowers were obtained elsewhere after 26 years of cultivation. The immense number of seedlings since that period have brought into universal attention blossoms of every form, size, and color, some even of bizarre and exquisite tints. The dahlia, from a coarse single scarlet, orange, purple, or lilac blossom, has at last vied with the proudest triumphs of the artistic skill of the floriculturist, as represented in the tulip or the rose. The choicest sorts are marked by the globular shape which the barren florets or petals assume, more than by their color, though the richest hues and the most delicate tints obtain in some, which command great prices when first offered for sale. Facility of propagation soon places such within the reach of every one, and competition brings out others of newer styles from year to year. The chief requisites to secure good flowers seem to be a rich soil, abundance of moisture, and judicious pruning of superfluous shoots. Several insects are injurious to the growing plants, some boring into the stem and destroying the young stalks, others eating the buds before half grown; but their destruction is easy.

DAHLMANN, Friedrich Christoph, a German historian of Swedish descent, born at Wismar, May 17, 1785, now (1859) officiating as professor of history and political science at the university of Bonn. He is the author of a celebrated work on the history of Denmark (3 vols., Hamburg, 1840–'43); also of *Vita Ansgarii* (in Pertz's *Monumenta Germaniæ Historica*); of *Forschungen auf dem Gebiete der deutschen Geschichte* (2 vols., Altona, 1822–'23); edited the *Chronik von Dithmarsen* (2 vols., Kiel, 1827); and wrote a history of the English (3d ed. Leipsic, 1843) and French revolution (Leipsic, 1845). As secretary of a committee of the Schleswig-Holstein diet in 1815 he became conspicuous by his opposition to the Danish policy in regard to the duchies; and being appointed professor at Göttingen in 1829, he obtained there 8 years afterward a still wider political celebrity by his energetic protest against the abolition of the Hanoverian constitution, and by his consequent dismissal from the university, together with 6 other liberal-minded professors. In 1848 he became one of the leaders of the party in favor of constitutional monarchy, was deputed by the king of Prussia to the German diet, April 31, 1848, and afterward elected by the people to the Frankfort parliament, of which he was one of the most gifted and influential members. His influence prevailed particularly in the elaboration of the German constitution. The attempt, however, to make Germany an empire under a Prussian dynasty, soon proved a failure; as did the subsequent efforts of the party of Gotha, with whom he acted, and the parliament of Erfurt, to which he was elected. In 1852 he retired from political life, disappointed at the futility of his efforts.

DAHLONEGA, a post village and capital of Lumpkin co., Ga., built on a high hill in the midst of one of the richest gold-mining regions of the state; pop. in 1850, 735. The metal was first obtained from alluvial deposits, and afterward discovered imbedded in quartz. The surrounding hills are now completely riddled with mines, and several remarkably rich veins have been opened. A branch United States mint is established here, which, including the machinery, cost $100,000. The village also contains 2 churches and a newspaper office. Its Indian name was Tau-lau-ne-ca, or "yellow money."

DAHOMEY, a kingdom of Africa, on the Slave Coast, between Ashantee on the W. and Yarriba and Benin on the E., extends S. along the gulf of Guinea, and stretches indefinitely N. toward the Kong mountains. The whole coast from long. 7° W. to 8° E. goes under the name

of Guinea, and also of the Slave Coast, of which Dahomey forms the portion lying between the rivers Volta and Niger. This gives it an extent of about 180 m. in length, by 200 in width. At the commencement of the 18th century the coast was divided between the kingdoms of Dahomey and Whydah, the first warlike, the other effeminate. As a consequence, the rich and fertile country of Whydah was absorbed in 1727 by Dahomey, and now forms part of its limits. The country bordering on the coast consists of a plain of extraordinary fertility, whence the ground rises by a gentle ascent to a distance of 200 m. inland. The soil is a reddish loam, without rocks. No river of importance is found on the seaboard. Fertility depends on the periodical rains, which are copious and usually accompanied by tornadoes. By reason of the position of this country between lat. 6° and 10° N., every variety of vegetable product may be cultivated. Cotton, sugar, indigo, palms, spices, tobacco, grains, and fruits flourish. The banana, plantain, and cassada, pineapples, oranges, limes, guavas, and other tropical fruits, are abundant. Among the vegetable productions peculiar to the country are a variety of millet, or Guinea corn, a legume called *calavances*, or pea-beans, and a species of vegetable called ground beans, as also a berry said to possess the property of turning bitters and acids sweet. With all these advantages, little is produced for export. Yams and maize are grown by the natives for consumption, with a moderate quantity of palm oil for the coast traders. Formerly Dahomey carried on a large traffic in slaves, and the ferocious habits engendered by that trade are still a characteristic of the people. Elephants, tigers, leopards, buffalo, wild sheep, and goats are plentiful, as are boas and other serpents. Trees grow along the river courses to an enormous size, it being not uncommon to see a canoe formed from a single trunk capable of holding 70 to 100 persons. The horses are small but hardy. The climate on the whole is not unfavorable to health. A breeze called the harmattan blows for 3 months in the year, and tends much to purify the air. Abomey, the capital city of the country, is situated in lat. 7° 59′ N., lon. 1° 20′ E. Whydah, oftener called Griwhee, is the port of Dahomey. A route of about 100 m. passes through Favies and Toro to Abomey, the intermediate stations being Glegouch, where the French, English, and Portuguese have fortified trading ports; next Sabyeh, capital of the ancient kingdom of Whydah, and yet the residence of a Dahoman viceroy; and further on is Ardrah, or Aradah-Kassy, where the roads from Jakyn, Epeh, and Porto Novo on the coast, join the main road to Abomey. The villages are large and numerous, but many ruined sites testify to the ravages of war. Houses are built of adobe, covered with straw, and usually have attached a small slip of garden. Two field crops are grown annually, the time of sowing being the vernal and autumnal equinoxes. Agriculture has advanced but little beyond its first elements. The Dahomans fabricate cotton cloth, pottery, mats, and trinkets, beside spears, swords, daggers, clubs, and rude agricultural tools. Their money consists of cowry shells, of which it takes over 2,000 to represent one dollar. The king's revenue consists of gifts, annually presented at a festival, a tax on various articles of commerce, and the sale of wives. In other respects the Dahomans are subjected to the most ferocious despotism of which we have any knowledge. The life of every man except that of the prime minister, and the persons of all females, belong to the king. Once a year the women are required to appear, that the monarch may make his selection. He retains a large number for himself, and distributes the rest as wives to his subjects, who are required to pay for them and be satisfied with his selection. The king is regarded as a fetich or deity. Doubtless this belief has much to do with the sanguinary customs which prevail at his court. Even the highest officers prostrate themselves in the dust when they approach him. As he claims to be sovereign over life and death, his residence is paved with human skulls. Every year he holds a festival in which human sacrifices are offered, and persons are slain on the graves of his ancestors in order that their spirits may bathe in the blood. The sacrifice is of the nature of a religious ceremony. Faith is placed in charms and amulets. A serpent is regarded as the sacred symbol of Whydah, and a tiger of Dahomey. The notion of a future state is that each person shall occupy precisely the same position he did on earth. The only visible objects of worship, at least on the coast, are a reptile which they call *Dabooeh*, which has its temples and priests, and certain idols of clay, to which the women offer worship. Snelgrave, who spent some time among this people, thinks they have a vague belief in a supreme, invisible deity, of whom idols are but the symbol. Next to the prime minister, called the *tamegari*, ranks the grand master of the ceremonies (*mayboo*), who joins the premier in selecting a new sovereign among the children of the deceased monarch. The other officers of state are the *agaoo*, commander-in-chief, having under him 3 generals called the *possoo*, *zohinoo*, and *fasapah*; next in rank is the viceroy of Whydah, entitled the *ivogan*, and next the superintendent of the king's household, styled the *yaoo*. Provinces, cities, and villages are governed by officers called *kabashirs*, who pay an annual tribute, collected from the heads of families. Polygamy is the custom of the country, the king having 3,000 to 5,000 wives; great men have from 200 or 300 downward, in proportion to their wealth; while most of the people can afford but one. The Dahoman language is an idiom of that spoken along the whole Guinea coast. It has no written character, although the Ardrah dialect has a symbol alphabet. A curious feature of Dahoman life is that the members of the king's harem form his body guard, and are regularly disciplined as soldiers.

They number 3,000 to 5,000, and form, in all respects, a portion of the army. In time of peace his total military force, male and female, is about 17,000, and in time of war 24,000. They fight with great ferocity. Apart from their disregard of shedding blood, the manners of the Dahomans are mild. They have a considerable degree of intelligence, but are indolent, and place much of their happiness in eating and sleeping. The dress of the men consists of trousers of native calico, and on high occasions a jacket without sleeves, the head being covered and the feet bare. The female costume is a robe or wrapper of cloth, with bracelets of beads and shells on the neck, wrists, and ankles, rings on the fingers, and pendants in the ears. Children are nursed 3 years, and circumcision is practised. Tattooing is occasionally performed as an embellishment. The Dahomans are of the same race as the Ardrahs, and are distinguishable from their neighbors by a darker complexion. They are, in general, of medium height, and well proportioned.—Dahomey first became of importance in the eyes of Europeans about the beginning of the 18th century, when the king was named Trudo. This sovereign conquered the strip of country lying between him and the sea, and opened a trade with the Europeans. He had frequent quarrels with them, and finally destroyed the French, English, and Portuguese factories at Xavier in Ardrah, beside hanging Mr. Testefole, the English governor. Trudo was succeeded by his son, Bossa Ahadee, whose first act of sovereignty was to put to death every person of the name of Bossa within his dominions, as a punishment for their presumption in bearing the same name as the king. He died in 1774, and was followed by a succession of savage rulers, who engaged in shocking atrocities to supply the slave trade. Since the suppression of that traffic, Dahomey has sunk in importance. Wars with the adjoining states have been attended with varying success. Not long since the Eyeos or Ayohs obtained the mastery over the Dahomans, and compelled them to pay tribute. It is said the Dahomans have once more gained the ascendency; also that the present king has put a stop to human sacrifices.

DAIRY. See Butter, Cattle, Cheese.

DAIS, a raised floor at the upper end of ancient dining halls, where the principal persons sat at table. The term also designated a seat with a canopy over it for those who sat at this table. The same name is applied in some monarchies to the canopy which hangs over the throne, and at Rome the pope is borne beneath a dais in solemnities which require him to traverse the streets and public places.

DAISY, or Day's Eye (*bellis perennis*, Linn.), a little perennial plant, native of Europe, and better known in its varieties than as a species. It was formerly employed for edgings to borders, and patches set in the turf of lawns frequently mown present a very pleasing appearance. In a wild state, the flower is borne upon a long slender peduncle. The florets or petals are numerous, narrow, white-tipped with a slight stain of crimson, in a single row around the central florets of the disk. In this form it is called single, but by cultivation it has become very double or multiplex, and has run into many curious and beautiful varieties. Of these the hen and chickens is the most singular, where the main flower heads are surrounded by several smaller flower heads. Beside this, which is known as the *prolifera*, the older sorts were the large double and the double quilled, the latter a deep rich crimson, with globular heads, and mostly cultivated as a pot plant. Of late years considerable attention has been directed to raising new sorts, and the catalogues enumerate choice varieties of white, blush, rose color, striped, and other diversities of hues. Division of the plants, which make numerous offsets, is an easy and practicable mode of propagation.

DAKEL, El, or El Dakleh, the western oasis of upper Egypt, 28 m. long by 15 m. wide. It has a very fertile soil, prolific in dates, olives, and other fruits. It contains several ruined towns, a remarkable temple, and a number of small villages, the principal of which are El Kasr and Kalamoon. Pop. estimated at between 6,000 and 7,000.

DALAYRAC, Nicolas, composer of *Les deux petits Savoyards*, and of many other French operas, born June 13, 1753, died in Paris, Nov. 27, 1809. He first became known to fame by a composition performed at a freemason festival given in honor of Benjamin Franklin.

DALBERG, or Dalburg, a noble family of Germany, mentioned as early as 969, and so much respected that at each imperial coronation the herald was required to proclaim: "Is there no Dalberg present?" whereupon the member of the family who happened to be present stepped forward and was knighted by the emperor. Among its most distinguished members are: I. Johann, bishop of Worms, born in 1445, died in 1503, an active and able patron of literature and science. II. Wolfgang Heribert, born in 1749, died Sept. 28, 1806, the friend of Schiller, and a zealous patron of the German drama. At the time of his death he was state minister in Baden. III. Emmerich Joseph, duke and peer of France, son of the former, born at Mentz, May 30, 1773, died April 27, 1833. He officiated as ambassador of Baden in Paris, where he became a favorite of Talleyrand and one of the diplomatic agents of Napoleon. Naturalized in France in 1810, he exerted himself in 1814 in favor of the restoration of the Bourbons, and attended, as French plenipotentiary, the congress of Vienna; after the 2d restoration he was a minister of state. IV. Johann Friedrich Hugo, born May 16, 1760, died in July, 1803, filled high functions in the Roman Catholic church, at Treves, Worms, and Spire, wrote on antiquities and music, and was himself a composer. V. Karl Theodor Anton Maria, the last archbishop elector of Mentz, and archchancellor of the German empire, born at Herns-

heim, Feb. 8, 1744, died in Ratisbon, Feb. 10, 1817. He studied at Göttingen and Heidelberg, and in 1772 became administrator of the territory of Erfurt, which then belonged to the elector of Mentz. He soon rose to a high position among the dignitaries of the church, and on July 25, 1802, became archbishop elector of Mentz. In the following year, when the territory of Mentz was secularized, the dioceses of Ratisbon, Aschaffenburg, and Wetzlar were assigned to Dalberg. In 1806, when the empire was dissolved, Napoleon made him prince primate of the Rhenish confederation and grand duke of Frankfort-on-the-Main. After 1813 he lost all his territories, only retaining the archiepiscopal dignity. His *Grundsätze der Æsthetik* (Frankfort, 1791) was much esteemed in its time.

DALBY, Isaac, an English mathematician, born in Gloucestershire in 1744, died Oct. 14, 1824. He was intended by his friends for a cloth worker, but, laboring by the aid of a few mathematical books to fit himself to be an usher, was employed in that capacity. Going to London in 1772, and being appointed to teach arithmetic in Archbishop Tenison's grammar school, he became known to many men of science, and was employed in making astronomical observations in a building erected for philosophical purposes by Topham Beauclerk. When this establishment was broken up, after being employed in various other situations of a similar nature, he became mathematical master of the naval school at Chelsea. In 1787 he acted as an assistant to Gen. Roy in taking the trigonometric observations for connecting the meridians of Greenwich and Paris, and for 2 years was occupied in extending the triangulations through Kent and Sussex to the coast opposite France. Gen. Roy died in 1790, and the next year Dalby was engaged together with Col. Williams and Capt. Mudge to continue the survey of England. They began their operations by remeasuring the original base line, on Hounslow Heath, and under their care the triangulation was extended to the Land's End. On the formation of the military college at Wycombe, Dalby was appointed professor of mathematics in the senior department.

DALCHO, Frederic, an American physician and clergyman, born in London in 1770, died in Charleston, S. C., Nov. 24, 1836. His father, a Pole, retired to England on a pension after serving as an officer in the armies of Hanover. On his death, his son was invited by an uncle to Maryland, and received an excellent education in Baltimore. He studied medicine and natural science, and became a practitioner in Charleston, where he was active in establishing the botanic garden. Subsequently he devoted himself to theological studies, became lay reader in St. Paul's church, Colleton, in 1814, and having received priest's orders was elected assistant minister of St. Michael's church, Charleston, in 1819, in which position he remained till his death. He published a treatise on the "Evidence of the Divinity of our Saviour," and a "Historical Account of the Protestant Episcopal Church in South Carolina."

DALE, a S. E. co. of Ala., bordering on Fla.; area, about 900 sq. m.; pop. in 1850, 6,346, of whom 721 were slaves. The surface is hilly and mostly occupied by pine forests. The soil is sandy and unproductive. In 1850 it yielded 2,158 bales of cotton, 182,396 bushels of corn, and 69,408 of sweet potatoes. Number of pupils in the public schools, 190. Capital, Newton.

DALE, David, the originator of the Lanark mills, Scotland, born at Stewarton, Ayrshire, in 1739, died in 1806. He was at first a journeyman weaver, and afterward became a great cotton manufacturer, at first in conjunction with Sir Richard Arkwright, and then on his own account. He was remarkable for the care which he took to provide teachers and the means of mental instruction for the thousands of people, old and young, to whom he gave employment at his works. He is described as "one of the most benevolent men of the last century." His daughter was married to Robert Owen.

DALE, Richard, a commodore in the U. S. navy, born near Norfolk, Va., Nov. 6, 1756, died in Philadelphia, Feb. 26, 1826. He commenced his career in the merchant service at the age of 12, and made several voyages between Virginia and Liverpool. When the revolutionary struggle commenced, Virginia, in common with several of the maritime colonies, organized a marine of its own, composed of small vessels, which were employed in the bays and rivers, and on board one of these Dale was appointed a lieutenant, in the early part of 1776. He had the misfortune to be captured soon after by a tender to an English frigate, and was thrown into a prison ship at Norfolk. Here he was surrounded by royalists, among whom were many of his old schoolfellows, who at once set about his conversion to the cause of the mother country, and he was finally induced to embark in a cruiser against the vessels of the state. Hostilities were now very active, and the vessel in which he was serving soon engaged an American flotilla, from which she was compelled to run after a heavy loss. Dale received a wound in this affair, with which he was confined several weeks at Norfolk, during which time he formed a resolution, as he said, "never again to put himself in the way of the bullets of his own countrymen." In after life, he always spoke with perfect candor and sincerity of the great error which he had committed by his momentary abandonment of the cause of his country. Immediately after the declaration of independence, we find Dale a midshipman in the brig Lexington, under the command of Capt. John Barry, in which vessel he served actively, under different commanders, until the autumn of 1777, when she was captured upon the coast of France by the English cutter Alert of 10 guns, after a very close and severe action. She was at this time commanded by Capt. Henry Johnston. The Alert took her prize into Plymouth, and the prisoners were placed in con-

finement in Mill prison, upon a charge of high treason, where they remained until Feb. 1778, when most of the officers and several of the men escaped. Dale found his way to London, where he was recaptured, and immediately carried back to Mill prison. Here he was held a year longer, subjected to the most unfeeling and insulting treatment, when he escaped a second time, in the disguise of a British naval officer. The manner in which he obtained his disguise and other facilities, he always refused to disclose. He succeeded in reaching France, and hastening to L'Orient joined a force then equipping under the celebrated John Paul Jones. He was now about 23, and after serving for some months as master's mate, Jones, discovering that he was an accomplished seaman, made him first lieutenant of his own ship, the Bon Homme Richard. On Aug. 15, 1779, the squadron sailed from Groix, and on Sept. 19 the memorable battle between the Bon Homme Richard and Serapis, a new ship of 50 guns, took place off Flamborough head. Dale distinguished himself highly in the battle, and received a severe wound by a splinter, with which he was laid up for some time. The Bon Homme Richard was so completely cut to pieces, that she sank soon after the engagement. The rest of the squadron put into the Texel, Jones having shifted his flag to the Alliance, and afterward to the Ariel, in both of which ships Dale still served as first lieutenant. On Feb. 18, 1781, he arrived at Philadelphia, and was regularly put on the list of lieutenants in the navy. He now parted from Paul Jones, with whom he had served nearly 2 years, and in June following joined the Trumbull, 28, Capt. Nicholson, which about 2 months afterward was captured off the Delaware, after a very severe action, by the Iris, 32, and Monk, 18. Dale was wounded in this action, making his 3d wound and the 4th time he had been captured during the war. He was taken to New York, and exchanged in the following November, when he received a furlough, and was employed in letters of marque and the merchant service until the close of the war. Under the law of 1794, he was appointed a captain in the navy, and ordered to superintend the construction of one of 6 frigates, which were directed to be built to resist the aggressions of Algiers. An arrangement with that regency was made, however, in consequence of which the building of the ships was suspended, and Dale was again placed on furlough. With the exception of a short cruise in the sloop Ganges, during our difficulty with France, he was not again in the public service until 1801, when he was appointed to the command of a squadron of 3 frigates and a brig, ordered to the Mediterranean, in consequence of hostilities with Tripoli, although war did not actually exist. His flag ship during this command was the President, 44, Capt. James Barron. This was an exceedingly well appointed squadron, but our policy at that time with regard to the Barbary states was so uniformly timid, that there was but little for it to do. The Tripolitan admiral, with two of his cruisers, was blockaded by one of our frigates in Gibraltar, while the rest of the squadron proceeded up the Mediterranean. A severe action occurred between the brig Enterprise, Lieut. Comdt. Sterrett, and a Tripolitan of equal force, in which the latter was compelled to surrender; but as there was no legal authority to detain her, she was liberated. Although the commodore was so fettered by his instructions that no serious enterprise could be attempted, his vigilance was so great that the Tripolitans made no capture during his command. In April, 1802, he returned to the United States, and in the autumn of that year resigned his commission, and was never again in service.

DALE, Sir Thomas, a colonial magistrate sent from England to Virginia as high marshal in 1609, and again in 1611, with 300 colonists, supplies, and new laws. The town of Henrico, on James river, was founded by him, and that of the Appomattox Indians at the mouth of the river of that name taken. He remained in the colony, and took an active part in its affairs, after being superseded by Sir Thomas Gates in 1611, and when the latter returned to England in 1614, again assumed the chief command. He went himself to England in 1616, and afterward to the East Indies, and there died.

DALECARLIA, or Dalarne, an ancient province of Sweden, celebrated in Swedish history for its noble struggles in behalf of national independence, and for the bravery, probity, and hospitality of the inhabitants. It was among the mountains of Dalecarlia that Gustavus Vasa took refuge from the Danish king Christian II., and by the aid of the Dalecarlians he was first enabled to make head against Denmark. Dalecarlia is now comprised in the province of Falun. The 3d son of the present king of Sweden bears the title of duke of Dalecarlia.

DAL-ELF (Dal river), the principal river of Dalecarlia, Sweden, formed by the union of the Oster and Wester Dal. It flows successively S. E. and E., and after a course of 250 m. from the source of the Oster Dal, during which it passes through a number of lakes, and forms several cataracts, it empties into the gulf of Bothnia. Except near its mouth, it is only navigable for rafts.

DALGARNO, George, a British philologist, born at Aberdeen about 1627, died at Oxford, Aug. 28, 1687. He was educated in the university of Aberdeen, and taught for about 30 years a grammar school at Oxford. In 1661 he published a work entitled *Ars Signorum, vulgo Character Universalis et Lingua Philosphica.* This was the basis of Bishop Wilkins's "Essay toward a Real Character." The work, however, by which he is best known in modern times is his "Didascalocophus, or the Deaf and Dumb Man's Tutor," which appeared in 1680. This work contains so fully the principles of deaf mute instruction, though deduced from theory only, that it would not be seriously defective as a handbook for the teacher at the present day.

He was also the inventor of the two-handed alphabet. His works were reprinted by the Maitland club (1 vol. 4to., Edinburgh, 1834).

DALGAS, Carl Frediuk Isak, a Danish scientific agriculturist, born at Fredericia in 1787. He studied at Copenhagen, and in 1808 was commissioned by the government to go abroad to study new modes of agriculture, and particularly the cultivation of hemp. Returning in 1810, he began to cultivate a farm, practising with his own hand the agricultural principles he at the same time promulgated with his pen.

DALHOUSIE, James Andrew Broun Ramsay, marquis of, a British statesman, born April 22, 1812. The earl of Dalhousie, his father, officiated for a time as governor of Canada. The present marquis was educated at Harrow and Oxford, entered the house of commons in 1837 as member for Haddingtonshire, and on the death of his father (March 21, 1838) took his seat in the house of lords. In 1843 Sir Robert Peel made him vice-president, and in 1844 president of the board of trade. On the accession of the whigs to office in 1846, he was requested to retain his position. In Nov. 1847, he went to India as Lord Hardinge's successor in the post of governor-general, and entered upon his duties Jan. 12, 1848. On the death of Runjeet Singh, the various Sikh chieftains who had been kept in check by his vigorous rule broke out into hostilities. Lord Hardinge had been compelled to march against them, and had vanquished them in the battles of Moodkee and Ferozeshah. On the breach of the treaty then concluded, and new risings in Mooltan, where several British were massacred, Lord Dalhousie invaded northwestern India, and having subjugated the Punjaub, annexed it permanently to the British empire. It was also under his administration, in 1852, that Pegu was annexed. Several minor annexations also took place, and the close of his official Indian career was marked by the annexation of Oude. The effects of the climate having destroyed his health, Lord Dalhousie resigned, and was succeeded by Lord Canning in March, 1856. On her voyage home Lady Dalhousie had already died (May 4, 1853). He was raised to the rank of marquis in 1849; appointed warden of the cinque ports on the death of the duke of Wellington in 1852; and rewarded in 1856 with a life pension of £5,000 by the East India company, which he resigned, however, in favor of the sufferers from the Sepoy rebellion of 1857.

DALIN, Olof, a Swedish author, born in 1708, died in 1763. His poetry, although popular at the time of its appearance, is now but little read in Sweden; but his historical works are still highly esteemed. His most extensive work, *Svearikes historia* ("History of Sweden"), appeared in Stockholm, in 4 vols., 1747–'62, and a German translation was published at Wismar, 1756–'63.

DALLAS, the name of counties in several of the United States. I. A S. W. co. of Ala., intersected by Alabama river, which is joined within the county by the navigable river Cahawba and several smaller streams; area, about 890 sq. m.; pop. in 1850, 29,727, of whom 22,258 were slaves. It has an uneven surface and a highly productive soil, skilfully and extensively cultivated. The surface rock is rotten limestone. Good water was formerly scarce in many parts of the county, but the deficiency has lately been supplied by a number of Artesian wells, from 200 to 900 feet in depth. The staple productions are cotton and Indian corn, and the harvest of 1850 amounted to 35,275 bales of cotton (the greatest quantity produced by any one county of the United States, except Tuscaloosa co., Ala.), 1,267,011 bushels of Indian corn, 227,298 of sweet potatoes, and 106,525 of oats. There were 45 churches, and 1,773 pupils attending public schools. Capital, Cahawba. The Alabama and Mississippi railroad passes through the co. II. A N. E. co. of Texas, drained by the forks of Trinity river; area, 900 sq. m.; pop. in 1856, 5,738, of whom 502 were slaves. Most of the land is fertile, well watered, and plentifully supplied with timber. The soil is suited to the production of cotton, grain, and wheat, and in 1850 yielded 44 bales of cotton, 94,870 bushels of Indian corn, and 35,520 lbs. of butter. The county contained 1 church and 1 newspaper office, and the public schools numbered 170 pupils. Capital, Dallas. III. A central co. of Ark., bounded W. by the Washita, and E. by Saline river; area, about 860 sq. m.; pop. in 1854, 5,894, of whom 2,526 were slaves. The Washita is navigable in this part of its course for boats of light draught. The soil is generally productive, and the surface level or moderately uneven. Indian corn and cotton are the staples. In 1854 there were raised here 5,343 bales of cotton, 212,809 bushels of Indian corn, 15,304 of oats, and 4,574 of wheat. The public schools in 1850 numbered 194 pupils, beside which there were 124 attending other schools and academies. Capital, Princeton. IV. A central co. of Mo., intersected by the Niangua river, an affluent of the Osage, and drained by several small streams; area, 576 sq. m.; pop. in 1856, 4,620, of whom 96 were slaves. Water power is abundant and valuable, and in several places there are excellent springs of limestone water. There are no great elevations in the county, and most of the surface is occupied by prairies and forests. The soil is good, but better adapted to grazing than to the cultivation of grain. Indian corn, wheat, oats, and live stock are the staples. In 1850 the productions were 187,580 bushels of Indian corn, 8,858 of wheat, and 65,795 of oats. There were 375 pupils in the public schools. Capital, Buffalo. V. A central co. of Iowa, traversed by Raccoon river and Beaver creek; area, 576 sq. m.; pop. in 1856, 3,991. The soil is said to be of excellent quality, but little more than one fifth of the land is under cultivation. In 1856 it produced 4,864 bushels of wheat, 2,658 of oats, 58,945 of Indian corn, 3,830 of potatoes, 19,566 lbs. of

butter, and 5,256 of wool. Capital, Adell. VI. A new county in the peninsula of Florida. It is not included in the census of 1850.

DALLAS, Alexander James, an American statesman, born in the island of Jamaica, June 21, 1759, died at Trenton, N. J., Jan. 14, 1817. His father was an eminent physician, a native of Scotland, who had amassed a handsome fortune in Jamaica. With the double purpose of regaining his health and of bestowing the proper care upon the education of his children, he returned to Edinburgh while the subject of this notice was still young. The latter was placed at school in London, where he remained until the death of his father, which occurred soon after. He now became a student of law at the Temple, but was subsequently induced to accept a position in a mercantile house. Circumstances, however, afterward led him to abandon this, and he again resumed his studies. In 1780 he was married, and in the following year he determined upon settling in Jamaica. There he remained until 1783, leaving in April of that year for the United States. On June 17 he took the oath of allegiance to the state of Pennsylvania. Having established himself in Philadelphia, he had designed entering immediately on the practice of the law; but the rules of the courts requiring a residence of 2 years in the state before an attorney could be admitted to the bar, he obtained from Jonathan Burrall, commissioner for settling the accounts of the commissary and quartermaster's departments of the revolutionary army, a situation in which he could use to advantage the knowledge he had acquired in his brief mercantile career in London. On July 13, 1785, he was admitted to practise in the supreme court of Pennsylvania, and subsequently in the U. S. courts. Not being fully employed by his profession, he prepared his "Reports of Cases ruled and adjudged in the Courts of the United States and of Pennsylvania, before and since the Revolution," of which 4 volumes were published between 1790 and 1807. These reports are the oldest in the United States except Kirby's. Lord Mansfield is reported to have said of them: "They do credit to the court, the bar, and the reporter; they show readiness in practice, liberality in principle, strong reason and legal learning; the method, too, is clear and the language plain." Considerable time was also given by him to other literary pursuits, in the preparation of numerous essays in the periodicals of the day, and in the editing of the "Columbian Magazine," published in Philadelphia. In 1790 Pennsylvania adopted a new constitution, under which Gen. Thomas Mifflin was elected in the same year its first governor. Mr. Dallas was, Jan. 19, 1791, appointed by Gov. Mifflin secretary of the commonwealth, an office which he filled for several years. While holding this position he prepared and published an edition of the laws of the state with notes. He was an ardent republican and a leading politician, and on the elevation of Mr. Jefferson to the presidency he received the appointment of U. S. district attorney for the eastern district of Pennsylvania, which office he held without interruption until he was called to the head of the treasury department. In May, 1813, Albert Gallatin, who had been secretary of the treasury from early in 1802, was sent on a special peace mission to Russia; and at the time, it being thought that his absence would be but temporary, no successor was named. The duties of the office were placed under the charge of Mr. Jones, then secretary of the navy, who after some months' experience found it impossible to do justice to them. In the winter of 1813–'14, it becoming evident to Mr. Madison that Mr. Gallatin would not soon return to the country, he resolved upon looking for a successor to him in the cabinet. Mr. Dallas was pressed to accept the office, not only by the administration, but by other distinguished public men. William Pinkney, the attorney-general, having resigned in Feb. 1814, the choice of these offices was tendered to him, but declined. While, as we have seen, Mr. Dallas was an undoubted republican, he did not entirely agree with the senators from Pennsylvania, Messrs. Roberts and Laycock, and it was more than intimated that an effort would be made by them to bring about his rejection by the senate in case of his nomination. On Feb. 9, George W. Campbell, a senator from Tennessee, was appointed secretary of the treasury. From his report to congress, Sept. 26, it appeared that the government was almost threatened with being brought to a stand for the want of means. In March previously, congress had authorized a loan of $25,000,000, of which $10,000,000 was advertised for in May; and although contracts had been made for the amount, $2,000,000 of it had not been paid by the parties contracting. In August the secretary had further advertised for $6,000,000, of which he had been able to negotiate but about $2,500,000, and even that sum at a discount of 20 per cent., with the additional provision that should the United States dispose of any further loan at a larger discount, the parties making this purchase were to be placed upon the same footing. The report of the secretary further indicated an imperative necessity of raising for the 2 last quarters of the year the sum of $25,000,000, while he estimated the actual revenue at $4,800,000. Having exhausted the means of borrowing, and with this deficiency threatening him, it was clear that more vigorous measures were imperatively necessary; but Mr. Campbell suggested no practical means of removing the difficulty. His health and spirits were broken down by the cares and anxieties of his office, and on Sept. 28 he resigned. Such was the position of the treasury when Mr. Dallas was again pressed to accept office. So alarming was the crisis, that those who had a few months before threatened to cause his rejection, were glad to withdraw their objections. He was accordingly nominated, Oct. 5, and con-

firmed the following day. On Oct. 14, John W. Eppes, the chairman of the committee of ways and means, addressed a communication to the secretary, asking for any suggestions from him respecting any "additional provision which may be necessary to maintain unimpaired the public credit." Three days after the receipt of this communication, he sent to that committee a report which to this day is one of the most remarkable papers which have emanated from the treasury department. It is distinguished alike by its bold and manly tone, the clearness with which the causes of existing evils are laid bare, and above all by the confidence which its author displays in his ability to grapple with and finally overcome the difficulties with which he had to contend. While he recognized the fact that the most important cause of difficulty was the inadequacy of the system of taxation to produce the revenue necessary even to base a credit upon, he at the same time added: "The exigencies of the government require a supply of treasure for the prosecution of the war beyond any amount which it would be politic, even if it were practicable, to raise by an immediate and constant imposition of taxes." Further, he assured them that there must be a resort to credit, which was too greatly impaired to hope to obtain adequate succor on moderate terms. Hence it became the object first and last in any practical scheme to reanimate the public confidence. He then submits in detail 6 propositions, in substance as follows: 1. That during the war there be raised the sum of $21,000,000 for the support of government, principal and interest of public debt created before the war, interest on public debt created or to be created during the war, payment of treasury notes, payment of debentures, addition to sums raised by loans, and for sinking and contingent funds. 2. The particular manner of raising the amount so required, by taxes and duties, is subjoined. 3. That a national bank shall be incorporated for 20 years, with a capital of $50,000,000, $\frac{2}{5}$ of which shall be subscribed by the United States, the remainder by corporations or individuals; that of the subscription of the latter $\frac{1}{5}$ shall be paid in gold or silver, the remainder in gold or silver, or in 6 per cent. stock issued during the war, or in treasury notes; the subscription of the United States to be paid in 6 per cent. stock; that the bank shall loan to the United States $30,000,000, at 6 per cent., at such times as shall be found mutually convenient. Other provisions with reference to the organization and government of the bank were also added. 4. That after having thus provided for the punctual payment of the interest upon every denomination of the public debt, for raising annually a portion of the current expenses by taxation, for establishing a sinking fund, and for securing to the public the efficient agency of a national bank, the only remaining object of supply shall be accomplished by annual loans, and issues of treasury notes, if unexpectedly such issues should continue to be necessary or expedient. 5. Contains a plan of settlement of accounts. 6. After a statement showing a necessity for providing for the 4th quarter of the year the sum of $19,176,391, he proposes to meet this by means of actual revenue, the negotiation of loans, and the issue of treasury notes. As early as Oct. 24, a resolution of the house was passed in committee of the whole, declaring it expedient to establish a national bank. In November a long and excited discussion took place in congress on the subject, opinions being conflicting and apparently irreconcilable. On Nov. 27, the secretary of the treasury was applied to by Mr. Lowndes, the chairman of the bank committee of the house, to know what would in his opinion be the effect of a large issue of treasury notes, which should be received in payment of subscriptions to the bank stock. The same day he made a reply in the same prompt and fearless spirit as the former report. "Whether Mr. Dallas was right or wrong in his bank plan," says a distinguished historian of that period, "his tone to congress, in the face of the country, and before the world, was a stirring appeal to the rising spirit of the nation." For a time the national bank project failed by reason of the difficulty of harmonizing the different views and plans; but in the few weeks of his administration, Mr. Dallas had already by his energy and ability greatly restored the public credit. He negotiated in October, on favorable terms, the loan which Mr. Campbell had failed in procuring in August; and after much discussion, in Jan. 1815, a bill chartering a national bank was passed, and on the 30th was returned by the president with his objections, which were to the effect that from the nature of the plan it would fail to accomplish its object. This bank was very different from the one proposed by the secretary, and, requiring too large an amount of coin, would have had but little influence on the fiscal affairs of the government. Finally, on April 10, 1816, a bill with less objectionable features, which had passed both houses, received the signature of the president and became a law. The practical effect of Mr. Dallas's administration of his department may be seen in the fact that treasury notes, which on his entering office in Oct. 1814, "none but necessitous creditors, or contractors in distress, or commissaries, quartermasters, and navy agents, acting as it were officially, seemed willing to accept," were on Jan. 10 following sold at par with interest added. This was also notwithstanding the fact that congress had failed to act with promptness and energy in carrying out his recommendations. Peace, however, having been declared on the ratification of the treaty of Ghent, Feb. 17, 1815, a great change immediately took place in the finances of the country, rendering extraordinary expenditures and loans unnecessary, except as temporary measures. In Nov. 1816, Mr. Dallas resigned the position which he had held with so much credit to himself and advantage to the country, leaving the national finances in the

most flourishing condition. When it became known that he intended to resign, he was urged to allow his name to be used as a candidate for congress from Philadelphia; but this he promptly declined, intending to resume the practice of his profession. His plans were, however, soon frustrated by his death from an attack of gout in the stomach, of 24 hours' duration. Various marks of respect were paid to his memory by the citizens of Philadelphia, by the various courts of the county, and by the supreme court of the United States, which recognized his "illustrious talents in professional, and eminent virtues in private life." One among his political opponents thus spoke of him at that time: "As a husband, a parent, and a friend, he was confessedly most amiable and exemplary. But it was by the sweet amenity of his disposition, his open hospitality, and the genial courtesy of his deportment, that he conciliated, even in the worst times of party contentions, so large a portion of the community."

DALLAS, George Mifflin, an American statesman, born in Philadelphia, July 10, 1792. He was the 2d of 3 sons of Alexander James Dallas, the eldest of whom, Commodore A. J. Dallas, a distinguished officer of the U. S. navy, died in 1844. George M. Dallas was graduated at Princeton college in 1810, and commenced the study of the law under direction of his father, and in April, 1813, was admitted to the bar. The United States being then at war with Great Britain, and the emperor Alexander having offered to mediate between the belligerents, Albert Gallatin was selected to fill the special mission to St. Petersburg; and from him Mr. Dallas received the appointment of private secretary, which he accepted. On his arrival in St. Petersburg, Mr. Gallatin found that Great Britain had declined the proffered mediation; but Mr. Adams and he resolved to ascertain if possible what were the views of that government; and with this object, Mr. Dallas was sent to London with despatches to the Russian ambassador at the court of St. James. This movement resulted in the appointment of the commission to Ghent, which after prolonged negotiations ended in the treaty of Dec. 24, 1814, which closed the war. Mr. Dallas, after a residence of several months at Ghent, was sent home by the American commissioners as bearer of important despatches, after which he held for about a year a position in the treasury department; relinquishing this, he entered on the practice of his profession in Philadelphia, and became the solicitor of the U. S. bank. In 1817 he was appointed by the attorney-general of Pennsylvania his deputy for Philadelphia county. During the presidential canvass of 1824 he took an active and important part, supporting Jackson for that office, and Mr. Calhoun for vice-president. In 1828 he was elected mayor of the city of Philadelphia, which office he resigned in the following year on receiving the appointment of U. S. district attorney. This position he in turn resigned, on being elected to a vacancy in the U. S. senate in 1831, which he held until the expiration of the term, March 3, 1833. During this brief occupancy of office, he displayed ability in the advocacy of the recharter of the U. S. bank, and of a protective tariff, as well as of other important public measures. Declining a re-election, he was appointed by Gov. Wolf attorney-general of Pennsylvania, which office he held until 1835. On the elevation of Mr. Van Buren to the presidency, he was, in 1837, appointed minister to Russia. Being at his own request recalled in 1839, and the office of U. S. attorney-general having recently become vacant by the death of Felix Grundy, it was tendered to him by the president, but was declined, and he again resumed the practice of his profession in Philadelphia. In May, 1844, Mr. Dallas was nominated for vice-president by the democratic national convention at Baltimore, in connection with James K. Polk for president. The ensuing canvass, which was conducted with great spirit by the two great parties of the country, resulted in the election of Messrs. Polk and Dallas, who received each 170 out of 275 electoral votes cast. The great and important issues which this contest decided were the policy of the country with reference to the tariff of duties upon imports, and the annexation of Texas to the United States. While the friends of Mr. Polk everywhere boldly avowed themselves in favor of "annexation," they were by no means so unanimous in reference to the revenue policy, being in favor of what is termed free trade in one section, while advocating in Pennsylvania the most positive protectionist principles. The moral influence of the election of Mr. Polk was sufficient to bring about the annexation of Texas under the administration of Mr. Tyler 3 days before his successor was inaugurated. In his first "Report on the Finances," in Dec. 1845, Mr. Robert J. Walker, the secretary of the treasury in the new administration, took the most decided ground in favor of the abandonment of the protective policy, and recommended a system of duties for revenue alone, which led, on July 28, 1846, to the passage of the tariff of that year—a free trade measure. So nearly balanced in the senate were the friends and the opponents of this radical change in the revenue system, that on the resignation of the Hon. W. H. Haywood, jr., of North Carolina, the fate of the bill was felt to depend upon the vote of the Hon. Spencer Jarnigan of Tennessee, a whig, who was opposed to its passage, but who had received from the legislature of that state instructions to vote for a bill based upon the principles of that measure. Mr. Jarnigan, while he declined to vote for the bill, did not feel himself at liberty to vote against it, and he withheld his voice entirely. This made the result depend upon Vice-President Dallas, who gave his casting vote for the bill, and it thus became the law of the land. That Mr. Dallas was fully aware of the deep responsibility of this act is quite clear from his address to the senate upon

that occasion. While he stated that the bill was not without many faults, he believed that "ample proof had been furnished that a majority of the people of the states desired a change to a great extent, in principle if not fundamentally," and as well for these as for other weighty reasons, he was induced to take the step which he then took. Mr. Dallas occupied the office of vice-president until March 4, 1849, when he was succeeded by Mr. Fillmore. In 1855, he was spoken of as a candidate for the presidency, but his name was not brought before the convention of his party held in the following year. On Mr. Buchanan's signifying his desire to be recalled from London, Mr. Dallas was nominated to the senate on Jan. 31, and confirmed on Feb. 4, 1856, as minister to the court of St. James, a position which he still (1859) holds.

DALLAS, Robert Charles, a British author, brother of Alexander James Dallas, born in Jamaica in 1754, died at St. Adresse, Normandy, Oct. 21, 1824. The higher branches of his education were conducted under the celebrated James Elphinstone, the friend of Dr. Johnson, at his school at Kensington, London, where he met with Dr. Franklin as well as with Dr. Johnson. At a subsequent period he furnished to John Nichols a memoir of his preceptor, which was abridged and used in Nichols's "Literary Anecdotes." His name was entered at the Inner Temple, but relinquishing the law he returned to Jamaica about 1775, where he remained some 3 years, when he again visited England and was married. Once more he determined to settle in his native island, intending to fulfil the duties of an office to which he had recently been appointed; but he was unable to remain there long, the climate being unfavorable to the health of his wife. He visited the continent of Europe, and afterward came to the United States, for the purpose of again meeting with his brother. Early in 1797 he published the first of his works, entitled "Miscellaneous Writings," which was followed in rapid succession, between that date and 1824, by various books either original or translated, covering a wide range of subjects, including natural history, history, biography, and fiction. His writings are in 46 volumes of various sizes and styles. In 1803–'4 he published the "History of the Maroons" (2 vols. 8vo.), a work of authority which is often referred to at the present time. His sister, Charlotte Henrietta, having married Capt. George Anson Byron, R. N., an uncle of Lord Byron, Mr. Dallas at an early day took an interest in the poet, and soon discovered in his writings "the marks of the genius which has been since so universally acknowledged." Immediately after the publication of the "Hours of Idleness," Mr. Dallas commenced a correspondence with Byron, which was the beginning of an acquaintance which soon ripened into friendship. On the completion of his "English Bards and Scotch Reviewers," in 1809, Lord Byron placed it in the hands of his friend for publication. Mr. Dallas was at once strongly impressed with the power which it displayed, and which so much surprised those who had judged him by his previous book. "Were you sufficiently acquainted with my mind to be certain that it cannot stoop to flattery," said Mr. Dallas after reading the manuscript, "I would tell you that it rivals the 'Baviad and Mæviad.'" When, in March, 1809, Lord Byron for the first time took his seat in parliament, by his particular request Mr. Dallas accompanied him on that occasion. In July, 1811, Byron returned to England after an absence of more than 2 years, bringing with him the 1st and 2d cantos of "Childe Harold," which he at once presented to Mr. Dallas, with the remark: "They are not worth troubling you with." Throughout the intimacy which existed between Lord Byron and Mr. Dallas, the latter "did every thing that a friend could do to win him to the cause of virtue." After many unsuccessful attempts, much to his satisfaction Mr. Dallas succeeded in reconciling him to his sister Mrs. Leigh, from whom he had been estranged for several years. The intimacy between Byron and Mr. Dallas was entirely broken off some time before the death of the former; immediately after which last event, he announced and prepared for publication in London, "Private Correspondence of Lord Byron, including his Letters to his Mother;" which he believed himself fully warranted in doing, by permission, if not expressed, at least implied, by their author. An application for an injunction was made, however, by Byron's executors, and the publication was prevented. Nevertheless, Mr. Dallas almost at once commenced the preparation of his "Recollections of the Life of Lord Byron, from the year 1808 to the end of 1814," which he had nearly finished when he died, after an illness of 3 months. The book was subsequently edited and published by his son, the Rev. A. R. C. Dallas.

DALLES (Fr. *dalle*, a flagstone), a name given by the Canadian French voyageurs to deep chasms in rocks, forming a narrow passage for rivers. The word is applied by them to the trough itself, the walls of which are composed of rocky slabs. The most famous locality thus named is Long Narrows of the Columbia river, 43 m. above the cascades. In this passage of ½ m. in length, the river is compressed to 300 feet in width, and rushes impetuously between walls of basaltic rocks, which present the appearance of having been forcibly rent apart. Fremont found the narrowest place only 58 yards across, and the average height of the walls 25 feet.—Upon the Wisconsin river, 2 m. above the crossing of the La Crosse and Milwaukee railroad, is another locality called by the same name. The gorge, in sandstone, is 5 m. long; the vertical walls are sometimes more than 100 feet high, and are worn into fantastic shapes by the action of the water. When the stream is low, small steamboats may pass up and down; but in freshets the waters rush through with destructive violence. An arched bridge was

built in 1852 across the chasm, being 100 feet long and 100 feet above the bottom.

DALMATIA, a kingdom within the Austrian empire, forming a small coast strip along the E. shore of the Adriatic, and on the W. slope of the Julian Alps, which form its frontier toward Turkey, lies between lat. 42° 30′ and 44° 28′ N., and long. 14° 59′ and 19° 9′ E., and is the southernmost province of Austria; area, 4,928 sq. m.; pop. 432,337, mostly of Slavic descent, but there are also numerous Italians, Arnauts, Greeks, and about 500 Jews. The Roman Catholic religion is predominant; the non-united Greek church numbers about 80,000 adherents; other sects are less numerous. The formation of the frontier mountain chain (rising to a height of 6,000 feet), which has a picturesque and rugged outline, is of limestone, with many mammoth caves, not perfectly explored, and subterranean lakes and rivers; but the surface is dry and bare, the rivers and lakes drying up during the summer, and leaving to the inhabitants nothing to drink but cistern or marsh water. The slope is sudden, the rivers descending in cataracts; the few fertile valleys are narrow. The coast consists of bold promontories with deeply indented bays, before which a series of long and narrow rocky islands stretch in a S. E. direction nearly parallel to the Julian Alps, forming a great number of excellent harbors. The climate is mild along the coast, the average temperature at Ragusa being 59° F., and not severe on the mountains, ice and snow being almost unknown; rains prevail when the *bora*, a northerly winter storm, blows, but the average annual fall is only 12 inches at Cattaro and Ragusa, and further north somewhat more. In spite of this, the climate is not very healthy, owing to the swamps along the coast range of mountains. Notwithstanding the limited space of fertile land (about 2,500,000 acres), the country might support a far larger population but for the frequent emigrations, and the quarrelsome and indolent habits of the population. Husbandry and the rearing of cattle are neglected, and Dalmatia is less productive than any other dependency of Austria. The value of the products was estimated at about $5,000,000 in 1855, of which timber formed about ⅓, and olive oil, wine, liquors, fruit, hides, tallow, and wax, the rest. Olive oil is largely consumed at home, and 20,000 barrels are exported annually. About 8,000,000 gallons of good wine are produced, of which ⅞ are exported and ⅛ retained for home consumption. Of figs 1,000,000 lbs. are exported, beside great quantities of dates, oranges, almonds, and raisins. The grain crops supply only the local wants for 6 or 8 months, the deficiencies being imported from Turkey and Hungary. The sardine and tunny fisheries employ about 10,000 persons. The shipping comprises only 22,000 tons, chiefly small craft. The manufactures are insignificant, excepting the distillation of spirits and liquors, of which Maraschino is the most celebrated. The total exports are valued at about $2,500,000; the imports at $2,000,000.—Physically the Dalmatians are a fine race, tall, of regular features and dark complexion, and make excellent soldiers, particularly the Morlaks, who live in the interior. They are also daring sailors, and constituted the strength of the power and ascendency of Venice in the middle ages, the violent storms and the perilous navigation in the Dalmatian archipelago developing their vigor and skill. They love liberty and independence, and have almost always successfully withstood the aggressions of the Turks. Their language is Servian, the same Slavic dialect which is spoken by their neighbors in the Herzegovina. Education is much neglected. There are 5 theological seminaries, 4 gymnasiums, and 251 badly organized and ill-attended public schools. Dalmatia is divided into 4 districts, Zara, Spalato, Ragusa, and Cattaro, and contains, beside the 4 cities of the same names, 15 other cities, and 35 towns. The Turkish portion of the ancient domain of Dalmatia forms the present province of Herzegovina.—The Romans subjected Dalmatia after a struggle of nearly 100 years, under Augustus; and under Diocletian it was one of the most flourishing portions of the empire, he having his residence at Spalato. The Slavic race took possession of it about 620, when the great Germanic migration had scarcely left a trace of the ancient inhabitants. The N. portion of the country was conquered by the Hungarians during the 11th century, and the southern (the Herzegovina) surrendered itself to the protection of Venice, which, however, could not prevent it from being, in the 16th century, conquered by the Turks, who possessed for almost 100 years the whole of Dalmatia. By the treaty of Campo Formio (1797) Austria came into possession of the Venetian portion, united it with the Hungarian portion, and has since ruled Dalmatia with the exception of the period 1805–'13, when it was under the sway of Napoleon, who strove to develop its resources for a navy. Austria has begun in the last decade to increase its commercial prosperity; she has established a naval academy at Spalato, tried to deepen several harbors, and to encourage ship-building. Napoleon conferred the title of duke of Dalmatia upon Soult.

DALMATICA, a kind of cloak with long sleeves, the use of which came originally from Dalmatia. It was this garment which characterized those nations whom the Greeks and Romans designated under the name of barbarians. When the emperors Commodus and Heliogabalus appeared in public wearing it, it was regarded as a dishonor by the Romans, who like the Greeks thought men effeminate who concealed their arms in the folds of their cloak. In later times the dalmatica became the distinguishing garment of deacons, who still wear it when they assist the priest at the altar or at any other ceremony. According to Alcuin, Pope Sylvester was the first who made deacons exchange the *colobium* or robe with short sleeves for the dalmatica, because he blamed the custom of having the

arms uncovered. Artists usually represent St. Stephen, the first deacon, as clothed with a dalmatica, which is an anachronism. The form of the dalmatica was the same as that of the usual garment of the ancient oriental nations who bordered upon the Mediterranean. As now worn by Catholic ecclesiastics, it has lost its ancient shape. It is made of very stiff materials, like the chasuble, and the loose flowing sleeves are replaced by a short covering for the upper part of the arm, slit underneath, and cut off above the elbow.

DALRYMPLE, the name of a Scottish family which rose into importance about the beginning of the 15th century. The following are its most eminent members: I. James, viscount of Stair, born in Drummurchie, Ayrshire, in May, 1619, died Nov. 26, 1695. He received his education at the university of Glasgow, and in the 22d year of his age, while holding a captain's commission in the army, was appointed professor of philosophy. Having filled this position for several years with credit, he was admitted in 1648 an advocate at the Scottish bar, and soon rose to eminence in civil practice. He was secretary of the commissions sent in 1649 and 1650 to treat with Charles II., then an exile in Holland; and in 1657, on the recommendation of Gen. Monk, he was appointed by Cromwell one of the "commissioners for the administration of justice," as the judges of the court of session were then called. After the restoration he was appointed by Charles II. one of the new lords of session, but resigned office in 1663, from an unwillingness to take the declaration against the national covenant of 1638, and the solemn league and covenant of 1643, appended to the oath of allegiance. The king refused to receive his resignation, and made him a baronet. In 1671 he became lord president of the court, and availed himself of his position to make some improvements in the system of judicature. In 1681 he refused to take the new test oath, and was obliged to resign office. In the same year he published his "Institutions of the Law of Scotland," a work held in no less esteem in Scotland, as the grand text book of the law, than are Blackstone's Commentaries in England. In 1682 he experienced such persecution from government as rendered it necessary for him to take refuge in Holland, where he prepared for publication his decisions, and published in 1686, at Leyden, a Latin treatise entitled *Philosophia Nova Experimentalis*. He accompanied the prince of Orange to England, exclaiming: "Though I be now in the 70th year of my age, I am willing to venture that (pointing to his head), my own and my children's fortune, in such an undertaking." He was rewarded for his adherence to William and Mary by a reappointment to the presidency of the court of session, and was elevated to the peerage as Viscount Stair. II. John, earl of Stair, son of the preceding, died in 1707, was an advocate at the Scottish bar, and became secretary of state for Scotland. He was created an earl in 1703. His complicity in the Glencoe massacre has given an unenviable notoriety to his name. Influenced, as his apologists say, by an intemperate and remorseless zeal for the interests of the state, he conceived an intense hatred against the Macdonalds of Glencoe for their tardiness in taking the oath of submission. To him is ascribed the infamy of having united with Breadalbane and Argyle to obtain from William the order for the extirpation of the clan, without informing him of the submission of its chief, Mclan, and of carrying it into effect. After a full inquiry the Scottish parliament pronounced him the original author of the massacre, but failed to impute to him such criminality as would affect his life or his estate. III. John, earl of Stair, son of the preceding, born in Edinburgh, July 20, 1673, died there, May 9, 1747. He entered the army at the age of 19, and served with great distinction under Marlborough. On the accession of George I. he was appointed commander-in-chief of the forces in Scotland, and for several years was ambassador in France, in which capacity he distinguished himself equally by diplomatic skill and magnificence of living. Subsequently he lived many years on his estates, and is known to agriculturists as the first to plant turnips and cabbages in open fields in Scotland. IV. Sir David, better known as Lord Hailes, great-grandson of the 1st Viscount Stair, and an eminent lawyer and antiquary, born in Edinburgh, Oct. 28, 1726, died Nov. 29, 1792. He was educated at Eton, studied the civil law at Utrecht, and in 1748 was admitted an advocate at the Scottish bar. After 18 years of professional life, he was made a judge of the court of session, under the title of Lord Hailes. Ten years later he was appointed a lord of justiciary, a position which he held until his death. As a criminal judge he was distinguished by learning, dignity, and a leaning to the side of mercy. He wrote much on other than professional subjects. His publications, 48 in number, exclusive of articles in reviews and magazines, commence with the year 1751 and extend to 1790. The first was a volume of paraphrases and translations from the Scriptures by various authors; which was followed by the publication, with ample notes and illustrations, of a variety of memorials and original letters, throwing light upon the history of England and Scotland. In 1769 he produced a historical memoir of the provincial councils of the Scottish clergy, and "Canons of the Church of Scotland, drawn up in the Provincial Councils held in Perth, in the years 1242 and 1269;" and in the succeeding year a collection of old Scottish poems from manuscript, with many curious illustrations. In 1773 appeared his "Remarks on the History of Scotland," and in 1776–'79 his "Annals of Scotland" from the time of Malcolm Canmore to the accession of the Stuarts, his most popular and one of his most useful works. The same year he published an account of the Christian martyrs of Smyrna and Lyons in the 2d century; which was succeeded,

in continuation of the subject, by the 2 volumes of "Remains of Christian Antiquity." In his "Disquisitions concerning the Antiquity of the Christian Church," he combated many of the hypotheses of Gibbon regarding the origin and progress of Christianity. "An Inquiry into the Secondary Causes which Mr. Gibbon has assigned for the Rapid Growth of Christianity," published in 1786, was a more elaborate development of his ideas upon the same subject. His last work was a translation of the address of Q. Septimius Tertullus to Scapula Tertullus, proconsul of Africa, with notes, to illustrate the state of the church in early times. Most of these works were published at his own expense. V. ALEXANDER, brother of the preceding, born at New Hailes, Scotland, July 24, 1737, died in London, June 19, 1808. He entered the East India company's service at the age of 16, and for many years occupied the position of hydrographer to the company. His published works amount to about 60 in number, and include a great variety of subjects, though the greater part are devoted to Indian affairs. He also prepared some valuable charts of the eastern seas.

DAL SEGNO (It. from the sign), in music, a direction to the performer to recommence from that part of the piece to which the sign :𝄋: is prefixed.

DALTON, JOHN, an English chemist, the author of the atomic theory, and of that of the constitution of mixed gases, born Sept. 5, 1766, at Eaglesfield, near Cockermouth, in Cumberland, died in Manchester, July 27, 1844. With his parents, he belonged to the society of Friends. He received his first instruction at the school of his native village, and in 1781 became usher in a school kept by one of his relatives at Kendal, with which he remained connected until 1793. His favorite studies were mathematics and natural philosophy. In 1788 he commenced a series of important meteorological observations, which, in the course of some 5 years, amounted to the number of 2,000. The nature of his studies and his high moral character procured him an introduction to Mr. Gough, the blind philosopher of Kendal, who obtained for him in 1793 the appointment of professor of mathematics and natural philosophy in a college or seminary at Manchester, which was removed to York in 1799. Dalton continued his lessons to pupils of both sexes in private schools for years, occasionally giving lectures on the physical and experimental sciences in neighboring towns and cities. In 1793 he published his first separate work, entitled "Meteorological Essays." This was one of his most favorite pursuits, and he continued to collect and record meteorological observations until the period of his death. In the following year he gave an account of a singular defect in his own vision which rendered him incapable of distinguishing certain colors; green, red, purple, and blue, all appearing alike to him. He attributed this peculiarity to the color of the retina or of the fluids of the eye; but after his death, no abnormal coloration was discovered on dissection. In relating to a friend the manner in which he first discovered the defect, he stated that on one occasion, when a boy, he went to see a review of troops, and being surprised to hear the other boys admire the red coats of the soldiers and the purple sashes of the officers, he could not understand in what manner the red coats differed from the color of the grass in the fields where the review took place. He asked the boys what difference they could see between the two; and from the general burst of laughter he obtained in reply, he was led to suspect there must be some defect in his own vision, which rendered him unable to perceive the difference. This peculiar defect of vision, which is not very uncommon, has sometimes been called Daltonism in England, since the publication of his paper. The earliest papers of Dalton consist of contributions to an able periodical called the "Gentleman's and Lady's Diary." He afterward published articles in the "Memoirs of the Manchester Society," in "Nicholson's Journal," the "Philosophical Magazine," and the "Transactions of the Royal Society of London." In 1801 his daily occupation as a teacher in a school led him to write and publish an "English Grammar." In 1802 he wrote 6 dissertations for the "Memoirs of the Manchester Society," in one of which he unfolded his celebrated theory of the "Constitution of Mixed Gases." His views on this subject were for some time strongly opposed by eminent chemists, but they are now universally received. The leading feature of this theory is that gases which do not form new chemical compounds act on each other as a vacuum, diffusing themselves among each other by their own elasticity. The greater part of the experiments of Dalton were made with a view to ascertain the influence of heat in the production of physical and chemical phenomena; and much of the progress of modern science in this department is due to his researches. Other subjects treated in these papers were the "Force of Vapor of Water and other Fluids at Different Temperatures in the Torricellian Vacuum, and under Atmospheric Pressure," and the "Theory of Evaporation and the Expansion of Gases by Heat." These works display profound reasoning based on accurate observations; and beside establishing the high philosophical reputation of the author, have rendered great service to the progress of pneumatic chemistry, and of modern investigations on the specific gravity of gases. The celebrity of Dalton, however, rests mainly on his atomic chemical theory, which he began to work out in 1803. The first developments of this new theory were deemed obscure and unsatisfactory by English chemists; nor did they generally receive it after he had done his best to make it plain. Dr. Wollaston, however, investigated the subject carefully, and admitted the truth of the system at an early period; and Berzelius gave a masterly analysis of the atomic

theory, and placed it on an elevated basis of authority. Prof. Thomson of Glasgow, and Dr. Henry of Manchester, gave many luminous and popular illustrations of the doctrine in England; and Dalton, before he died, was universally honored in his native land, as well as among men of science in all other civilized countries. The atomic theory is said to be a consequence of the investigations of Richter; a theory which that laborious experimentalist did not perceive, but which, it is affirmed, was obscurely indicated in a paper by Dr. Higgins. It is, nevertheless, acknowledged now that the first development of its general principles, and the important consequences of its application to the explanation of chemical and natural phenomena, are due to Dalton. The atomic theory was fully propounded by Dalton in his "New System of Chemistry," the 1st volume of which appeared in 1807, and the 2d in 1810. These were followed by a 3d in 1827. The elements of the mathematical principles of the science are fully explained in these important volumes. In his papers on subjects connected with meteorology, he has left valuable remarks on evaporation, rain, the aurora borealis, winds, and dew. His observations on the latter contain the principles of Dr. Wells's theory of dew, and of Daniell's hygrometer. In 1822 Dalton visited France, where he was received with much distinction. In the reign of William IV. the English government gave him a pension of £150 a year, which was subsequently increased to £300. In person, Dalton was of middle stature, with a good constitution, though not robustly formed. His early habits as a member of the society of Friends had given him a quiet, grave demeanor. He was never married.

DAM, an obstruction of wood, stone, or earth, raised to keep back a current of water, either for the purpose of giving power by increased head, for holding back supplies of water, for flooding lands, or for rendering the stream above the dam navigable by increased depth. The earliest dam builders were the beavers. With clay and earth bound together with sticks, they construct durable piles across rivers, and cause the marshy lands above to be converted into extensive ponds. Their dams in districts long since deserted by them remain as monuments of their wonderful sagacity. In Maine they have sometimes proved, with the materials accumulated upon them, serious impediments to the running of logs down the streams, and the opening of a way through them has often been a matter of great labor and expense. Some of the dams constructed for manufacturing purposes in New England are among the most remarkable of this class of works. The largest probably in the United States is that completed in Oct. 1849, at South Hadley Falls, 8 m. N. of Springfield, Mass. It is 1,017 feet long, and 28 to 32 feet high, built of timbers a foot square each, which are laid in tiers crossing each other and bolted together, bedded and secured at bottom 4 feet in the rock, and all having a slope up stream. The spaces are filled in with stone 15 feet from the bottom, and gravel is laid over this and in front. The whole width at base is 90 feet, and the slope from the top to the upper edge of the base is 21.5°. It is covered with 6-inch plank bolted to the timbers, and the ridge is double planked, and where most exposed to ice is further protected with a covering of boiler plate iron. The structure consumed about 4,000,000 feet of timber. The roar of the vast sheet of water falling over the dam is said to be heard sometimes at the distance of 40 miles; and the vibrations are at times distinctly perceived at Springfield, where the windows and doors of some of the houses are rattled in uniform pulsations with those observed at the dam. These have been counted by Prof. Snell of Amherst, and found, when the temperature of the air was 80°, to be 137 per minute. With the temperature at 70°, the vibrations were 130. The subject of the vibrations of dams appears to have been first discussed by Prof. Loomis, in a paper in the "American Journal of Science," vol. xlv., p. 363 (1843). He cites several instances of this phenomenon, which appears to have been sometimes a cause of serious annoyance to persons living in the vicinity of dams thus affected. Its occurrence was found in several cases to be dependent on the water falling in an uninterrupted sheet; and the vibrations ceased when this sheet was divided by a floating log catching upon the top of the dam, or by strips of wood secured at intervals upon the ridge for the same purpose. Prof. Loomis discusses the probable cause of the vibrations, and mode in which they are communicated to distant objects, whether through the air or the rock. The subject was treated by Prof. Snell in a communication presented to the American association for the promotion of science, at the Montreal meeting in 1857; and again by Mr. Charles Stodder of Boston, in a paper read the same year before the natural history society of Boston.—Probably the highest dam ever constructed is that described by Minard in his *Cours de construction des ouvrages qui établissent la navigation des rivières et des canaux* (Liége, 1851, p. 204). It is in the province of Alicante in Spain, between two steep mountains which closely approach each other. Its height is 156½ feet, its thickness at top 69½ feet, and its length 272½ feet. The aqueduct for the outlet of the water is excavated through the mountain on one side, discharging below the dam near its base; and the discharge is regulated by a gate above. The dam was built in 1594, and is used for collecting water in winter to be used for irrigating the vineyards in the neighborhood.—A Coffer Dam is a tight case constructed in any body of water to prevent its encroachment, while excavations are made within it for foundations or other purposes. They are commonly made by rows of piles driven into the bottom, those of each row sometimes close together, and sometimes connected by planking, and the space

between the two rows filled in with clay. When it happens that coffer dams are required upon a bottom of quicksand, their construction becomes a work of great difficulty and expense. This was especially the case in building the dry dock for the navy yard at Brooklyn, N. Y. For more than 60 feet below the superstratum of black mud, where the work was laid out, the bottom consisted of an impalpable sand containing much mica, and this when loosened and saturated with water flowed like a dense liquid body. In this material a pit was to be excavated covering a surface of over 2 acres at top and over one at bottom, reaching 42 feet below the surface of the ground, and 37 below mean high water. Piles of yellow pine 35 to 40 feet long, and 15 inches square, were first driven in close contact, forming 3 rows around the outer end of the proposed excavation, the intervals between the rows being 10 and 12 feet. These were filled in with the sand excavated. The piles were tied together with oak wales and 2-inch tie bolts. This barrier was forced inward by a pressure of less than 10 feet head of water, and when the excavation reached 30 feet the water came in under the piles and filled the pit. This was in July, 1846; in September, after the breach had been repaired, the water again burst in, and some of the piles settled down 5 to 6 feet. A new and stronger dam was then the only expedient. Piles 10 to 15 feet longer than the others were driven close together in 2 rows 30 feet apart, outside the old work, and the space between the 2 rows was filled with gravel and coarse stone. A third row was driven within the old work, to the depth of 12 to 15 feet below the proposed level of the foundation, and gravel filled in behind them. Thus constructed, the dam was retained in place during the progress of the excavation only by the closest attention and care. Unsupported within, it could be stayed only in a few places by mooring chains carried to the shore. These cables, made of 2-inch iron, were repeatedly snapped asunder by the pressure. Six of them broke in one night. The foundation was made with piles driven over the area of the pit, and upon these the masonry was laid. As the masonry was carried up it was used to brace against the dam. The pressure upon it moved at one time a mass of more than 250 tons weight. The whole number of piles employed in the dam was 3,504; and the total cost of this part of the structure alone was $206,378.

DAMAGRAM, a province of Central Africa, on the N. W. frontier of Bornoo, extending from lat. 13° 20′ to 14° N., and from long. 4° 30′ to 10° 50′ E. It is a fertile country, but the inhabitants are addicted to robbery and slave-stealing. Beside the tropical productions of Soodan, wheat, cotton, indigo, palms, melons, &c., are cultivated. The common domestic animals are found there, as are lions, wild boars and oxen, jackals, hyenas, &c. The capital was formerly a town of the same name, but is now Ziudoo, which name is sometimes given to the province. It is described in Petermann's "Account of the Expedition to Central Africa," 1854, and was visited by Dr. Barth in 1852.

DAMAR, a kind of indurated pitch or turpentine, the spontaneous exudation of various trees in the East Indian islands. It is used in China and Bengal in coating the bottoms of ships and for other similar purposes.

DAMASCENUS, Joannes, a saint and doctor of the church, born in Damascus about 676, died at the monastery of St. Sabas in Palestine in 780. His father, a Christian, held the office of chief secretary under the Saracen caliphs. On the death of his father, he was made by the caliph Ali governor of Damascus, which office was continued to him after the death of Ali and change of dynasty. The luxury and hazards of such a city were ill suited to his tastes, and after a few years he resigned his office, and became one of the hermits in the "Lama" of St. Sabas in the valley of the Kidron. The old monk who was here assigned as his spiritual instructor laid down for his observance the following 5 rules: 1, entire self-renunciation; 2, dedication of all labors and prayers to God; 3, utter humility, preventing all boast of learning or genius; 4, constant self-mistrust; 5, habitual silence and reserve, both in speaking and writing. He was sent to Damascus to sell baskets, for which he was required to ask an unreasonable price, and so to subject himself to the insults of the market in the city which he had ruled. He did not hesitate, departed on the journey, and persevered until the price was paid. On another occasion, having consoled a brother monk in affliction by repeating a Greek verse, he was excluded from his cell for this exhibition of scholastic vanity, as they chose to consider it, and was only restored after the most humble protestations and the promise to become the scavenger of the monastery. When his monastic virtue had been sufficiently confirmed by repeated tests, he was admitted to the priesthood, and was allowed to write against heretics and in defence of religious customs. His first essay was against the Iconoclasts, whose doctrines were supported by the edicts of Leo the Isaurian, at this time emperor. His most elaborate work was his "Accurate Summary of the Orthodox Faith," a compendium of the doctrine of the church in the 8th century. Supplementary to this treatise he published numerous special essays on controverted points of theology, philosophy, and ethics. In the Monothelite and Monophysite controversies he took an active interest. He wrote a treatise on the "Trisagion," to confute the Eutychians; a work called "Parallels," which lays down rules of practical morals; an abstract of Aristotle's logic and physics; a discussion of the "Eight Principal Vices;" a work on Lent and the proper method of observing it; a biographical sketch of the monk Stephen the Younger; with various other essays. He contributed numerous hymns to the ritual of the Greek church, and his authority as a doctor and a saint is very high

in all the East. His festival is observed both in the Roman and Greek churches. The best edition of his works is that of the Dominican Le Quien (2 vols. folio, Paris, 1712, republished at Verona in 1748).

DAMASCENUS, Nicolaus, a Greek historian and philosopher, contemporary and favorite of the emperor Augustus and Herod the Great. He was born at Damascus, studied with Herod, resided at his court, and went to Rome 13 B. C., where Augustus received him with favor. Of the numerous writings of Damascenus we have only some fragments, the most important of which are from his work on universal history. They are frequently referred to by Rawlinson, in his recent translation of Herodotus, in illustration of obscure passages in that historian.

DAMASCIUS, an ancient philosopher, born probably at Damascus about A. D. 480. He studied for a time at Alexandria, and then went to Athens, where he was first a student, and then a teacher, of the Neo-Platonic philosophy. When the heathen schools at Athens were closed by order of Justinian, A. D. 529, Damascius went to the court of Chosroes, king of Persia; and although he afterward returned, little is known with regard to the remainder of his life. His works, some of which are extant, included a philosophical treatise entitled "Difficulties and Solutions of First Principles" (Frankfort, 1828), and commentaries on Aristotle and Plato.

DAMASCUS (Arabic, *Dimeshk* or *Esh Sham*), anciently the capital of Syria, and justly accounted one of the oldest cities in the world, is situated in lat. 33° 32′ N., long. 36° 20′ E., 136 m. N. of Jerusalem, 180 m. S. W. of Aleppo, and about 45 m. E. from the Mediterranean, at an altitude of 2,344 feet above sea level, in a very fertile and extensive plain, 80 m. in circumference, remarkable for its beauty, so much so as to be called, in oriental phrase, one of the 4 terrestrial paradises. The streams from the adjacent high range of Anti-Libanus, the Barada or Chrysorrhoas, and the Awadj, are supposed to be coincident with the Abana and Pharpar of Scripture (2 Kings v. 12). For many miles the city is surrounded by fertile fields and gardens, which are watered by rivulets and sparkling streams, giving to the vegetation a charming freshness and sweetness. It is nearly 2 m. in length, and half a mile in breadth; it is 6 m. in circumference, and has a double brick wall on 3 sides, and on the 4th a small square citadel flanked with towers. On the whole, it is regular and cleanly for an oriental city; its streets are long and narrow, and tolerably paved with basalt; and its residences, though mean and unattractive externally, are many of them full of magnificence and luxury within. The market places are well constructed, and adorned with marble colonnades. The bazaars are numerous, larger than those of Aleppo, and more airy and better lighted than those of Cairo and Constantinople. Each class of merchants and artisans has its own bazaar, some of them being very extensive, as those of the goldsmiths, the druggists, the traders in cotton stuffs, the pipe makers, &c. The great khan of Damascus is a vast and striking building, filled with various commodities, and frequented by merchants from distant lands. Many of the khans are of great antiquity, and afford even in their present state a good idea of the manner in which business was conducted in ancient times. The mosque of Abd el Malek, 650 feet in length by 150 in breadth, is the chief architectural ornament of the city. There are several other mosques of much beauty, 4 Jewish synagogues, and Greek, Maronite, Syrian, and Armenian churches. The palace of the pasha is a large fortified building in the centre of the city. The population of Damascus has been estimated as high as 200,000, but it probably does not much, if at all, exceed 150,000, comprising 130,000 Mohammedans and Druses, 15,000 Christians, and 5,000 Jews. Damascus is the centre of the commerce of Syria; and its trade is very much increased by its forming the rallying point of all the pilgrims to Mecca from the north of Asia. The number of pilgrims who make Damascus their place of rendezvous, with their attendants, amounts annually to several thousands. The city at such times presents the appearance of a vast fair, and every vacant place is filled with camels, horses, mules, and merchandise. Caravans proceed from Damascus also to Bagdad and Cairo. The principal imports by these various channels are broadcloths, different sorts of metals from the coasts of the Mediterranean, and shawls, muslins, and Indian stuffs, which are brought by way of England. Its own manufactures consist chiefly of silk and cotton fabrics, highly finished saddles and bridles, fine cabinet work, jewelry, gold and silver trimming, and excellent soap, made of olive oil, kali, and chalk. Pearls and precious stones, as turquoises, are to be met with in the bazaars, and large quantities of dried fruits and sweetmeats are exported to Constantinople, to the annual value, it is said, of $200,000. In former days, Damascus was celebrated for the manufacture of sabres of such superior excellence that they would bend to the hilt without breaking, while the edge was so keen as to divide the firmest coat of mail. (See Damascus Blades.) This very ancient city was built, according to some writers, by Uz, the son of Aram; it is repeatedly mentioned in the history of Abraham. It was the residence of the kings of Syria during 3 centuries, and has experienced many and great changes in every period of its history. Hadad, who is called by Josephus the first of its kings, was conquered by David, king of Israel, but its subjection was of short duration. In the reign of Ahaz it was taken by Tiglath-pileser, who slew its last king Rezin, and added its provinces to the Assyrian empire. It subsequently came under the rule of Babylonia and Persia. After the battle of Issus (333 B. C.) it fell into the hands of Alexander the Great, and soon after became a part of the dominions of the Seleucidæ. Pompey at-

tached it to the Roman empire. Its connection with the life and career of St. Paul is well known (Acts ix.; 2 Cor. xi. 32). Many Jews had settled in Damascus after its conquest by Alexander; and Christianity being early preached here, it became the seat of a bishop. Under the emperors, Damascus was one of the principal Roman arsenals in Asia, and is denominated by Julian, in one of his letters, as "the eye of the whole East." The Saracens took it shortly after the death of Mohammed, and afterward made it the seat of the caliphate, and the capital of the Mohammedan world. The Ommyïades reigned at Damascus for more than 90 years. On their fall the Abbassides, their successors, made Bagdad their capital. When the family of the Fatimites obtained the supremacy, Damascus fell under the sway of these Egyptian caliphs; but it was wrested from them by the Seljook Turks, under whom it was in vain besieged by Louis VII. of France and Conrad III. of Germany, in 1148. Just at the beginning of the 15th century it was taken by Tamerlane, after a protracted resistance, which so enraged the conqueror that he put its inhabitants to the sword without mercy. The Mamelukes repaired it, when they gained possession of Syria; but the Turks, under Selim I., took it from them in 1516. It thus became part of the Turkish empire. In 1832, Ibrahim Pasha took it, and added it to the pashalic of Egypt; but in 1840 it was restored to Turkey.—Damascus is the name also of a pashalic extending from the Jordan valley, the Lebanon range, and the river Orontes on the E., to the Euphrates on the W., and from Hamah on the N. to Petra on the S. It embraces the most of Palestine, a part of the country of the Druses, and a part of the Syrian desert. The pasha resides in Damascus, which is the real capital of Syria. He is the head of the civil and military government, and the protector of the caravans which annually proceed from Damascus to Mecca. There is little agriculture except in the vicinity of the principal city, but the district is noted for its horses, mules, camels, Arabian sheep, and bees. The population is estimated from 1,000,000 to 1,500,000, consisting chiefly of Osmans, Arabians, Turkomans, Greeks, Armenians, and Jews. The commencement of a macadamized road, 70 m. long, between Damascus and Beyroot, was celebrated Jan. 3, 1859.

DAMASCUS BLADES. These famous weapons, though in use among nations little skilled in the metallurgic arts, long before the Christian era, and made familiar to the European nations from the time of the crusades, have, until a very recent period, defied all attempts to imitate them, and to reproduce their remarkable qualities. It appears that the Indian wootz was in those ancient times carried from the region of Golconda in Hindostan (where, as well as in Persia, it still continues to be manufactured by the original rude process), and being delivered at Damascus, was there converted into swords, sabres, and scymitars, the qualities of which will for ages to come cause the name of this ancient city to be linked with the most perfect productions in steel. The articles were particularly distinguished for their keen edge, which seemed alike adapted for severing the heavy iron spears opposed to them, or cutting as by a flash of fire the most delicate gossamer fabric floating in the air and offering no opposing weight to the instrument. Their polished surfaces were covered with delicate lines appearing as black, white, and silvery veins, parallel to each other or interlaced and arranged in bundles of fibres, which cross each other at various angles, or in knots and bunches. Constructed without doubt by some exceedingly simple method, the highest skill of modern science was long taxed in vain to imitate this variegated or watered appearance, and the rare qualities associated with it. Methods of great ingenuity and complexity were contrived, by which some very good imitations were made; but it was not till after the investigations of M. Bréant and of the Russian general Anossoff, an account of which was published in the "Russian Mining Annual" a few years ago, that the subject was fully comprehended. Karsten remarks that the true Damascus (leaving aside the false, which is merely engraving upon a coating of some substance laid upon the steel) is a certain proof of a want of homogeneousness in the metal. All steel, even after melting, and malleable iron also, shows this texture, if polished, plunged in acid, and examined with a microscope; and the softer the metal the more decided this is. The Damascus appearance may be given to iron by welding together bars of different degrees of hardness, drawing them down, and repeating the process several times. Karsten suggests that by the use of bars of good steel the best oriental blades may have been fashioned in this way. Such was the "torsion" process of Clouet and Hatchette, the bars being well twisted between each welding. The "mosaic" process, also practised by them, differed from the other by cutting the bar into short lengths and fagoting these pieces, the cut surfaces always being placed so as to face outward. Blades of great excellence were thus produced, but still inferior to the genuine Damascus. Professor Faraday in 1819 detected aluminum in wootz by two analyses, and was inclined to refer the peculiarities of the steel to this alloy; but Karsten failed to find any appreciable quantity of this metal, and other chemists have sought in vain for this or any other ingredient, to which its excellence could possibly be attributed. Elsner entertained the opinion, which is generally received at Sheffield, that it is the remelting and working over of the steel that imparts to it such valuable properties. M. Bréant appears to have been the first to suspect the real nature of the Indian process. By producing the steel with a considerable excess of carbon, and by a suitable method of cooling, he found that two distinct compounds of the metal with carbon were formed, one of which may be steel, and the

other of a quality approaching cast iron. Left to cool slowly, these tend to separate from their confused mixture, and to crystallize, each quality by itself; the slower the cooling the more complete is this separation, and the coarser the bands of stripes or lines in the hammered steel. The steel was prepared by M. Bréant by melting soft iron with $\frac{1}{30}$ its weight of lampblack; a much more ready way of making steel than by the cementation process, but manufacturers have been slow to adopt and improve upon it. With this he made excellent blades, and also from filings of gray cast iron mixed with an equal quantity of the same oxidized, the materials being carefully stirred during their fusion. The more oxidized the iron the better the effect, a large proportion of carbon causing the steel to work badly under the hammer. Gen. Anossoff, however, who repeated these experiments, was not satisfied with the results, the steel appearing to him to have neither the true lines of the Damascus nor its excellent qualities. The Indian method of carbonizing the iron, which they obtain direct from the ore, getting only about 15 per cent. of metal from the magnetic oxide they employ, is to place it in crucibles made of clay, intermixed with straw, adding about 10 per cent. of dry wood in small bits, and cover it in the crucible with 2 or 3 green leaves; only a little more than a pound of iron is the charge of each crucible. They exercise a choice in the wood and leaves, selecting of the former the *cassia auriculata*, and of the latter the *asclepias gigantea* or the *convolvulus laurifolius*. The crucibles are then closely covered with moistened clay, rammed to exclude the air, and are placed, 20 or more of them together, in a small blast furnace, and, with charcoal for fuel, are kept at as high a temperature as possible for about 2½ hours. On removing them from the fire and cooling, they are broken, and the steel obtained in the form of a melted lump. If this is covered upon the surface with irregular protuberances, the quality is bad; but if the surface is smooth, and covered with striæ radiating from the centre, the operation has succeeded, and the steel is of excellent quality. Four or five of these lumps are commonly rejected. The best are remelted, and then, on account of their brittleness, they are exposed to a red heat for some hours in a small wind furnace, by which a portion of the carbon is removed, and the steel is softened, so that it can be easily drawn out under the hammer. This Indian steel, according to the opinion of Mr. Stodart, is far superior for cutlery to the best English cast steel. One of the best samples selected by Gen. Anossoff, and analyzed by M. Ilimoff, gave the following result: iron, 98; carbon, 1.131; sulphur, 0.014; silicium, 0.5; aluminum, 0.055; copper, 0.3; silver, traces. The researches of Gen. Anossoff were made with great minuteness of detail, and their results present many curious and interesting particulars, which are highly instructive as to the nature of this and other qualities of steel, and can be gathered from no other source. The information he acquired upon the subject led to the establishment of works at Zlatoosk in the Ural mountains, where the manufacture of Damascus steel is carried on by a process of his own invention. The quality of the steel he found to be indicated by the appearance of the lines upon the surface, by the color of the ground, and by that of the light reflected from its face. The scoriæ detached from the metal in forging receive from it the impression of its lines, and when examined by the aid of a microscope, they serve better to denote its character than the metal itself; but much experience is required to distinguish correctly the effects of the great variety of lines. Straight lines nearly parallel indicate a bad quality of steel. As they shorten and curve, the quality improves. It is still better when the short lines are broken up, and the spaces between them are dotted over with isolated points, particularly if they become like the meshes of a net, and are connected together by serpentine lines running in different directions. The most perfect quality of steel is indicated by the threads or lines forming little points or knots, and being arranged in groups of the same pattern over the whole surface of the steel. Figures coarsely and strongly marked are much to be preferred to fine delineations. The scoriæ also indicate the depth of the color of the steel; those of deep color and vitreous are the best. When the cooled surface of the melted steel in the crucible is not uniform and displays no colored reflections, the quality is bad. The more brilliant the lustre and the more decided the reflection, the better it is, especially if this has a golden yellow tint. It may also have a bluish or reddish color. The peculiarities of the lines—whether these are properly coarse, or whether they are too fine—appear to Gen. Anossoff to depend upon the proportion of carbon and the intimacy of its combination with the iron. The color of the watered lines and that of the ground depend upon the purity of the iron and the carbon; a ground of deep shade and brilliant lustre with undulations of white indicates purity of materials. The reflection which the surface of the steel gives is the best indication of the condition in which the carbon exists in it. In the yellow-colored only is the combination of carbon and iron complete. When the reflection is red, the carbon is mixed with some strange substance; and when there is no reflection, the carbon is apparently unaltered from its original condition, and the steel, if largely charged with it, is brittle. By 4 methods, Anossoff succeeded in producing steel of the Damascus qualities; only one, however, appears to be of practical importance. One, which was melting the ore with graphite, requires ore of great purity and a large consumption of fuel, and is not uniform in its results. It is supposed from its simplicity to have been the ancient method of producing this steel. The best method was melting the iron in crucibles with graphite. A charge of 11 lbs. of iron, or a

smaller one for a very hard steel, is introduced into the crucible with $\frac{1}{12}$ as much graphite, and $\frac{1}{32}$ part of scales of iron, together with a certain quantity of some flux, as dolomite. This being a very fusible flux, only about $\frac{1}{24}$ part is employed. Being well covered, the crucible is placed in the fire, and the blast is put on. In $3\frac{1}{2}$ hours the surface is covered with a thin layer of scoriæ, on which floats the excess of graphite; one-fourth of it has disappeared. The metal has acquired a weak display of longitudinal lines, a clear ground, and, if the graphite is good, a certain degree of reflection. By continuing the fusion for 4 hours the loss of graphite is $\frac{1}{3}$, and the lines are undulating. In $4\frac{1}{2}$ hours $\frac{1}{2}$ the graphite is taken up, and the lines attain a medium degree of coarseness. The crucible generally begins to fail at this point, but if it should retain its shape for 5 hours, $\frac{3}{4}$ of the graphite will have disappeared, the lines will be reticulated and of medium coarseness, and the scoriæ amount to nearly $\frac{1}{2}$ a pound in weight. By continuing, when possible, the fusion for another half hour, the graphite will nearly all disappear, the scoriæ will amount to $\frac{2}{3}$ or $\frac{3}{4}$ of a pound, and the lines upon the steel will become more or less decided, reticulated, and sometimes zigzag. The following are given as requisites for the best steel: charcoal of the cleanest sort, as pine; a furnace constructed of the most refractory materials; the best quality of crucibles; iron also the best, very malleable and ductile; pure native graphite, or that obtained by breaking up the best crucibles; flux of dolomite, or calcined quartz; a high temperature; fusion as long continued as possible. The blast of the furnace is kept on till the fuel is entirely consumed; and the crucible is not removed until it is cold, or at least black. The cover is then taken off, the graphite removed, the scoriæ are broken, and the lump of steel is extracted. When cold, this presents a surface of uniform appearance; or there may be a depression in the centre if the steel is very hard and shows no reflection; or if steel of this quality exhibits no outward depression, a cavity may be looked for in the interior of the lump, which is the effect of too rapid cooling, and indicates a very inferior quality. The lump, which weighs about 11 lbs., is drawn out under the hammer with 3 to 9 heats; it is then separated into 3 pieces, each of which is forged anew. Particular care is required in reheating to give the proper temperature. At a white heat the steel if hard will crumble; if tender, it loses the watered lines. The best steel may be drawn out cold without cracking, and may even become red hot by hammering. In working the bars into other shapes, they ought not to be heated beyond a clear red, and the last heat should not exceed a cherry red. It is well, as the lower part of the lump is always better marked than the upper, to keep the two original sides distinguished from each other, that the cutting edge may be formed out of the lower. In tempering steel, the different heats are distinguished by the different colors the metal assumes. These are the yellow, violet, blue, and green. The hardest temper is given at the straw-yellow, the greatest elasticity at the blue; at the green the metal begins to lose its elasticity. This is the temper for scythes; the violet for chisels. The very hard Damascus is tempered in grease; all sword blades and arms in boiling grease. They cool more quickly in this than in cold grease, as the former moves more freely around the object plunged into it. The temper is first given to the whole instrument heated to redness, plunged into hot grease, and left to cool. It is then taken out, wiped clean, and rubbed on one side with a whetstone, the better to judge of the proper temperature for reheating. A sabre blade is brought at the point to a blue heat, in the middle to violet, along the edge to yellow, and near the handle to green. When tempered it is dressed with the hammer, sharpened, and plunged while hot into cold water. Greater elasticity is given to the whole blade by bringing a larger proportion of it to a blue heat. The edge takes a harder temper by being filed thin. Razors and some other instruments are tempered in water; scythes need only to be swung in the air. The processes of grinding, whetting, and polishing are liable to remove the temper, particularly with very thin blades. After grinding they frequently require to be heated to a blue color and plunged into water; this is the process called blueing of steel. The grinding tends to bring the metal in places to a green heat, when it loses its elasticity in these places. This happens even if the stone is wet, provided the blade be pressed hard upon it. This accounts for the difference in razors made of the same steel. Rather than risk injuring the temper, it is better not to give a high polish to the blades and edges of instruments; those of Damascus steel do not need it, for after the lines are brought out by the application of acids, polishing beyond a slight rubbing with fine emery and oil is no improvement. This last process of bringing out the watered appearance is accomplished by the use of a diluted acid, which acts more upon the ground than upon the lines. All acids are not equally suitable for this purpose. Nitric acid acts not only upon the iron, but also upon the carbon, and moreover injures the lustre. Sulphuric acid, having no effect upon the carbon nor the reflection of the surface, is much to be preferred, especially when it is used in the state of a sulphate; and a sulphate of iron which contains a certain quantity of sulphate of alumina is found to produce the best effects. The blade, thoroughly cleaned, is washed with the solution by pouring it over the surface, and when the lines are developed it is repeatedly washed with soap and water, and wiped dry with a cloth, care being taken not to wet any portion after it has been once dried. Some vegetable acids, as lemon juice or vinegar, answer very well in place of the solution of sulphate of iron. The last operation is to rub the sur-

face over with pure olive oil and again wipe it dry.—The total expense of the production of blades by these processes is estimated at Zlatoosk to be about $1 10 per lb. They prove to be of similar properties to those of the famous oriental blades, the accounts of which have not been so much exaggerated as is generally supposed. Gen. Anossoff has himself, with a blade of reticulated lines in broad stripes and showing a bright gilded reflection, cut through a gauze handkerchief in the air, a feat which cannot be accomplished with the best English steel. Bones and nails may be cleft without injury to blades tempered for such use, and other steel tempered to the same point may be nicked by them without causing a gap. Their elasticity is so great, that one may put his foot upon the end of the blade and bend it to a right angle, when it will fly back perfectly unchanged. Razors are said to do at least twice as much service as those made of the best English steel. Articles requiring great sharpness and strength should be made of the harder quality of Damascus, that which displays the lines before the treatment with acids; those requiring great elasticity should be made of the softer quality, which is prepared with a smaller proportion of graphite. Atkinson in his late work on Siberia states that Gen. Anossoff died in 1851, and that his successor at the works had failed to produce the remarkable blades for which the establishment had become celebrated. The wonderful quality of the arms previously made there is particularly noticed by Capt. James Abbott, in his "Journey from Herant to St. Petersburg." The observations of M. Anossoff upon the introduction of other metals to alloy the steel are very minute, but they are all unfavorable to any mixtures with the iron and carbon.—These researches are particularly interesting, from their bearing upon the new process of producing cast steel, introduced into successful operation in this country, by melting malleable iron in crucibles with carbonaceous fluxes, thus avoiding the tedious and expensive process of cementation. For this operation see STEEL.

DAMASK, a fabric originally manufactured at Damascus, whence its name. It was made of silk, and was distinguished by its ornamental woven figures of fruits, flowers, animals, and landscapes. It is still distinguished by these ornaments, and by the mode in which they are introduced in the process of weaving, though the material of modern damask is often linen, sometimes indeed woollen, or even cotton, or a mixture of linen and cotton. The cotton fabric, from its want of durability and beauty, has little to recommend it for this manufacture, particularly as it is only by great care and frequent bleaching that it can be made to retain its whiteness. Its peculiar texture is that called tweeling or twilling, in which the warp and the woof cross each other, not alternately, but at intervals of several threads. These intervals being at every 8 threads in damask, the stuff is called an 8-leaf twill. The linen damasks manufactured at Dunfermline in Scotland, and at Lisburn and Ardoyne in Ireland, are used chiefly for table cloths and napkins. Diaper is a variety of damask, differing from it by the warp and the woof crossing each other at intervals of 5 threads.

DAMASKEENING, the art of ornamenting iron or steel by inlaying with gold, silver, or some other metal. It is used chiefly for adorning sword blades, guards, and locks of pistols. The most beautiful method of damaskeening consists in cutting the metal deep with a graver, and filling the groove with thick wire of gold or silver. In this way the wire adheres very strongly. The more common process is superficial only. For this, the metal is heated to a blue color; it is then hatched with a knife, and the figure desired is drawn with a fine brass bodkin upon the hatching. This done, a gold wire is conducted according to the pattern designed, and sunk carefully into the metal with a copper tool. Of late a method is in practice of eating out a cavity for the precious metal by means of acid. The art was carried to great perfection in Damascus, in Syria, whence its name. It is of great antiquity, its invention being attributed by Herodotus to Glaucus of Chios, 490 B. C.

DAMAUN, or DAMAN, a seaport on the coast of N. Concan, belonging to the Portuguese; pop. about 6,000. It is situated at the mouth of the Damaun river, on the gulf of Cambay, 100 m. N. from Bombay; lat. 20° 24′ N., long. 72° 53′ E. It has a fine appearance from the sea; its houses are whitened, and it contains several churches and convents, but the streets are narrow and dirty. It is fortified by a rampart and a castle. The river has a bar at its mouth, with 18 feet of water at high tide. It is a good port of refuge and of repairs for small vessels. Ship-building is carried on to some extent, but commerce is declining. The Portuguese sacked and burned the town in 1531, and in 1558 took formal possession of it. The territory which they hold here is 10 m. long and 5 m. broad.

DAMAUN, DAMAN, or THE BORDER, a district of the Punjaub, formerly included in Runjeet Singh's kingdom of Lahore, between lat. 28° 40′ and 33° 20′ N., long. 69° 30′ and 71° 20′ E.; length 300 m.; average breadth 60 m. It lies between the Indus and the Suliman mountains, and extends from the borders of Sinde N. to the Kala or Salt range. The irrigated portions are highly fertile, but other parts of the country consist of burning, sterile plains, sandy deserts, or jungles infested by wild beasts. The heat in summer is intense, but ice often forms in winter. The inhabitants are mostly Juts and Beloochees, dark-complexioned, ill-formed, and quarrelsome.

DAMBOOL, or DAMBOLO, a village in the island of Ceylon, with an immense rock about a mile distant, rising 550 feet above the plain, and called Damboollagalla. On its S. side, 100 feet from the summit, are 5 very remarkable caves, in which the Ceylonese monarch Walogambahu concealed himself during an invasion of the Mal-

abars, 100 B. C. In gratitude for the protection thus afforded, he ordered the caves to be enlarged, and converted them into Buddhist temples. Images of the god were placed there, priests appointed to conduct the worship, and the revenues of certain lands set apart for their support; and the service is still kept up. In one of the caves is a colossal statue of Buddha hewn out of the rock; a long inscription found in another is interesting for the information it conveys concerning the government of Ceylon during the 12th century.

DAMER, Anne Seymour, an English sculptor, only child of Field Marshal Conway, born in 1748, died May 28, 1808. She imbibed an early love for literature, and was celebrated for her accomplishments. A casual conversation with Hume turned her attention to sculpture, and she took lessons from Ceracchi and Bacon, and went to Italy to prosecute the art. She was also an excellent amateur actress. The productions of her chisel are numerous and admired. Among them are a bust of Nelson in the Guildhall, 2 colossal heads on Henley bridge, and a statue of George III.

DAMERGU, a frontier province of Bornoo, in Central Africa. The capital, Olaloal, lies in about lat. 14° 30′ N. There are said to be 200 or 300 towns and villages in the country. It is very productive, and the granary of Aïr, and chiefly inhabited by slaves of the Kelowis under the rule of the Tuariks.

DAMEROW, Heinrich Philipp August, a German psychologist, and superintendent of the insane asylum at Halle, born in Stettin in 1798, is one of the greatest authorities in Prussia on all subjects pertaining to insanity, established and still edits the *Journal für Psychiatrie*, and has written *Die Elemente der nächsten Zukunft der Medecin* (Berlin, 1829); *Ueber die relative Verbindung der Irren-, Heil-, und Pflege-Anstalten* (Leipsic, 1840); and *Sefeloge, eine Wahnsinnsstudie* (Halle, 1853).

DAMIANI, Pietro, an Italian prelate, born in Ravenna about 988, died at Faenza, Feb. 22, 1072. While young he entered the monastery of Font Avellana, of which he became abbot in 1041, and in 1057, greatly against his own will, was raised by Pope Stephen IX. to the rank of cardinal-bishop of Ostia. He persuaded the simoniacal Benedict X. and the antipope Cadalous to lay aside their pretensions; he vigorously supported the measures of which Hildebrand (Gregory VII.) was the prime mover, and he was in consequence persecuted by the disorderly clergy of Milan, to whom he was sent as legate. In 1062 he withdrew to his solitude at Font Avellana, but the next year was sent to France by Alexander II. to investigate the charges of simony against the French clergy. In 1069 he went on a similar mission to Germany, and in 1071 he left his monastery again to restore order in Ravenna, the archbishop of which city had been excommunicated. There are many editions of his writings, comprising sermons, lives of saints, treatises on church affairs, and a work on the abuses of the clergy.

DAMIENS, Robert François, executed in Paris, March 28, 1757, for his attempt on the life of Louis XV. He was born near Arras, in 1714, and his character was of the worst description. While a child he was called *Robert le Diable* on account of his wickedness. He enrolled as a soldier, but deserted; afterward robbed one of his employers, and fled to Belgium.

DAMIETTA (Arab. *Damiat*, anc. *Tamiathis*), a town of lower Egypt, on the right bank of the E. branch of the Nile, 6 m. from its mouth, and 100 m. N. N. E. from Cairo; pop. about 28,000, a few of whom are Greeks and Syrians, and the rest Egyptians. Its general appearance is that of a straggling collection of poorly built houses, relieved by magnificent mosques, bazaars, and marble baths, with a few brick dwellings of a better sort on terraces near the river. It has a military school for 400 infantry officers, a cotton-spinning factory, a large rice mill, and a good coasting and interior trade in dried and salted fish from Lake Menzaleh, rice, coffee, beans, dates, flax, linen, &c. It was once famous for the manufacture of leather and striped cloth, and the name of dimity given to the latter in Europe is supposed to be derived from it. Its foreign commerce was formerly large, but is now merged in that of Alexandria. Its harbor is bad, and is inaccessible by large vessels owing to a bar at the mouth of the Nile. The ancient town of Damietta stood about 5 m. nearer the sea than the present. Under the Saracens it rose to great importance, and the crusaders, looking upon it as the bulwark of Egypt on the Mediterranean side, made it the object of many attacks. In one of these sieges it was captured by the French king Louis IX.; but the victorious monarch, having fallen soon after into the hands of the Arabs, was forced to purchase his freedom by restoring the city to its former owners. The sultan of Egypt, about 1251, in view of the danger of its exposed position, razed it to the ground, built the present city, and blocked up that mouth of the Nile by which it communicates with the sea.

DAMIRON, Jean Philibert, a French eclectic philosopher, born at Belleville, May 10, 1794. A pupil of the normal school, he taught literature and philosophy in provincial colleges, and through the influence of Victor Cousin was called to Paris, where he occupied a chair of philosophy in 3 of the principal colleges, and was finally appointed professor of philosophy in the faculty of letters. In 1836 he was elected to the academy of moral and political sciences, where he succeeded Destutt de Tracy. He first published *Essai sur l'histoire de la philosophie en France au XIX^e^ siècle* (1828); next a *Cours de philosophie* (1831), treating of psychology, logic, and morals. His *Essai sur l'histoire de la philosophie au XVII^e^ siècle*, which appeared 15 years later, gives a synopsis of the philosophical systems of Descartes, Gassendi, Spinoza, Malebranche, Bossuet, and Fénelon, con-

cluding with his own opinions. In 1857 appeared his *Mémoires pour servir à l'histoire de la philosophie du XVIII^e^ siècle*. He also edited Jouffroy's *Nouveaux mélanges*, with an introductory notice, beside publishing a variety of miscellaneous philosophical memoirs, including sketches of Bayle, Leibnitz, Clarke, Helvetius, Diderot, and others.

DAMJANICS, János, general in the Hungarian war of 1848–'49, born in the Military Frontier district of Austria in 1804, executed at Arad, Oct. 6, 1849. Though a Rascian by birth, and serving in one of the regiments of his native district, he early drew upon himself the attention of his Austrian superiors by manifestations of a liberal and national Hungarian tendency. After the outbreak of the Hungarian war he was for this reason to be sent to Italy, but he was retained by the Hungarian ministry, and subsequently sent as commander of the 3d and 9th battalions against his own countrymen, the Rascians, in southern Hungary. His gigantic stature, unsurpassed valor, and revolutionary rigor, soon made him the favorite of the army and nation, and the terror of the hostile tribes. He won the battles of Lagerndorf (Nov. 9, 1848), of Alibunar (Dec. 17), and when recalled to join the chief central army, the decisive battle of Szolnok (March 5, 1849); and in the spring campaign of Görgei he had the chief merit in the successive victories of Izsaszeg (April 6), Waitzen (10th), Nagy-Sarló (19th), and before Comorn (26th). Having accidentally hurt his leg, he was prevented from entering upon the office of substitute minister of war, which was tendered him, as well as from further service in the field. Made commander of the reconquered fortress of Arad, he surrendered 4 days after Görgei (Aug. 17) to the Russians, who soon delivered him up to the Austrians. He was hanged after having witnessed the execution of 12 fellow officers.

DAMM, Lake of (*Dammische See* or *Dammsche See*), a lake in the circle of Stettin, province of Pomerania, Prussia. It is formed by the expansion of the Oder, near its mouth, is about 10 m. in length by 1½ in breadth, and is navigable in its whole extent. It receives the waters of the Ilna and the Plöne.

DAMOCLES, one of the courtiers of Dionysius the Elder, tyrant of Syracuse. Damocles had extolled the happiness of Dionysius in being a rich and powerful king, and the latter, wishing to show him the nature of that happiness, placed him one day at a magnificent banquet, with a naked sword suspended above his head by a single hair.

DAMON and PYTHIAS, the names of two celebrated Syracusans, which are always joined as the types of true and noble friendship. They were both Pythagoreans. Pythias, or correctly Phintias, was condemned to death by Dionysius the Elder, but requested to be temporarily released in order to arrange his affairs, promising to procure a friend to take his place and suffer his punishment, if he should not return. Pythias was allowed to depart, and Damon gave himself up as his substitute. Before the time appointed for the execution, Pythias returned, and Dionysius set both of them free.

DAMOREAU, Laure Cinthie (Montalant), a French vocalist, born in Paris, Feb. 6, 1801. Her parents were employed as *concierges* in the conservatory, and Laure was not yet 7 when she became one of the pupils of that institution. Her talent attracted the attention of Plantade, one of the professors, who admitted her into his singing class, and afterward introduced her to Louis Napoleon's mother, Hortense, who became interested in the little girl. In 1819 she made her first appearance in Paris under the name of Mademoiselle Cinti; but her reputation was not established until 4 years afterward. In 1827 she left the Paris opera and went to Belgium, where she married M. Damoreau, an actor connected with the theatre of Brussels. One of her most memorable achievements was in 1829, when she sang in the first act of the *Matrimonio segreto* together with Malibran and Sontag, without being eclipsed by either of those artists. In 1844 she took leave of the French stage, and made a professional tour in the United States; after which she became professor in one of the singing classes of the conservatory. She has published a *Méthode de chant*, an *Album de romances*, and some fugitive pieces.

DAMPE, Jacob Jacobsen, a Danish professor of philosophy, born in Copenhagen, Jan. 10, 1790, died in 1850. The liberal sentiments of his lectures on philosophy gave umbrage to the government, and he was detained in prison from 1821 to 1841, when Christian VIII. restored him to liberty. He contributed many articles to religious and political publications, and is the author of a work on Danish orthography, of literary essays in prose and verse, and of a variety of books, the chief object of which is to show the compatibility of liberal institutions with the spirit of the Christian religion.

DAMPIER, William, an English navigator, born at East Coker, Somersetshire, about 1652; the date of his death is unknown. His father, a farmer, destined him for commercial pursuits, but having become an orphan at an early age, the boy's guardian took him from school, and sent him to sea as a common sailor, in which capacity he made voyages to Newfoundland and the East Indies. War having broken out between England and Holland, Dampier enlisted on board a ship of war, was present in two actions, fell sick, was invalided and sent home. On recovering, he undertook for 6 months the overseership of a plantation in Jamaica. Disliking that obscure life, he made several voyages in a Jamaica coaster. At Kingston he became acquainted with a party of lumberers about to sail for the bay of Honduras, to cut mahogany, and readily agreed to join them. He remained with them 3 years. Returning to London in 1678, he published a description of the bay of Honduras. In the succeeding year he left London for South America, with the intention to

resume lumbering; but at Jamaica he met with a party of buccaneers, who were about to make a descent on the Spanish main, and he and his comrades joined them. The party crossed the isthmus to the Pacific. On the Pacific coast, with their small boats, they boarded and captured several ships, which they converted into cruisers, and with them pillaged the cities on the Peruvian coast. An immense amount of plunder fell into their hands, but they quarrelled so much about its distribution that Dampier left, and arrived in Virginia in 1682. On Aug. 23, 1683, he set out with a privateer, Capt. John Cook, for the Pacific ocean, via Cape Horn. Cook's expedition cruised along the coasts of Chili, Peru, and Mexico, making depredations on the Spaniards. In 1685 Dampier joined the command of Capt. Swan on the coast of California, in hopes to intercept the Spanish Manila galleon; but that rich prize did not fall into their hands, and they set sail for the Philippine islands. After many hardships they arrived, in a perishing condition, at the isle of Guam; thence they steered for Mindanao, the crew being in a state of mutiny; at this place they set ashore Capt. Swan, and those who were favorable to him. Dampier continued to cruise with the mutineers in the Indian archipelago, where he noted some islands hitherto unknown, and in the course of the voyage touched at New Holland, or Australia. Having become disgusted with the excesses of his companions, he secreted himself with 7 others on one of the Nicobar islands, and on the departure of the buccaneers, put to sea in a canoe to reach the English factory at Acheen, Sumatra. A tempest threw him on the coast, but at length he reached his destination. From Acheen he made several commercial voyages to Tonquin, Malacca, Madras, and Bencoolen. At the latter place he held the office of master of the artillery for 5 months. From Bencoolen he embarked for England, where he arrived Sept. 16, 1691, and published his "Voyage around the World." He dedicated the book to Charles Montague, earl of Halifax, president of the royal society, by whom he was recommended to the admiralty, who gave him the command of the Roebuck, a government vessel of 12 guns, for the purpose of exploring the coast of New Holland. With this ship he set sail from the Downs, Jan. 26, 1699, and having run across to Brazil, turned his course eastward to the coast of New Holland, which he traced for nearly 300 leagues. Being unable to effect any communication with the natives, he bore up for the Dutch settlements to refit. On his departure he threaded the archipelago, and on Jan. 1, 1700, came on the coast of New Guinea, which he surveyed, passing through the strait which separates that island from New Britain, and which bears his name. After numerous other discoveries, he returned by a new route to Ceram, in the Moluccas. On his way to England, his ship foundered off the island of Ascension. Dampier and his crew saved themselves; 2 months after, in 1701, they were taken from the island by a passing ship, and carried to England, where he published an account of the expedition. Government seems to have been dissatisfied with the result, for it gave him no further employment. The rest of his life is obscure. In 1703 we find him making an unsuccessful cruise as master of a privateer belonging to a company of English merchants, and again in the capacity of pilot to a privateering expedition, under Capt. Woods Rogers, in 1711. In 1707 he published a defence of his buccaneering on the Spanish main. He also wrote a treatise on winds and tides. Dampier's style of relating his adventures is interesting; his descriptions are vivid, and his facts generally correct. The best edition of his collected voyages appeared at London in 1729, in 4 vols. 8vo.

DAN. I. One of the sons of Jacob. II. A tribe of Israel, descendants of the preceding, and the division of Palestine allotted to them. The latter was bounded by Ephraim, Benjamin, Judah, and the Mediterranean. III. A town of Palestine, on the northern boundary, called Laish before its conquest by the Danites from the Phœnicians.

DAN RIVER, a river of Va. and N. C. It takes its rise at the foot of the Blue Ridge in Patrick co., Va., and flows S. E. into Surrey co., N. C. It then turns E., and after a winding course of 200 m., during which it 5 times crosses the boundary between the 2 states, and drains a tract of country 4,000 sq. m. in extent, it unites with the Staunton, or Roanoke river, at Clarksville, Va. It is navigable by boats as far as Danville, Va.

DANA, Francis, an American jurist, born at Charlestown, Mass., June 13, 1743, died at Cambridge, April 25, 1811. He was graduated at Harvard college in 1762, and was admitted to the bar in 1767. The state of public affairs at this period attracted the zeal or the foresight of the young men of most promise in the profession. He joined the "Sons of Liberty," and John Adams's diary of Jan. 1766, speaks of the club in which "Lowell, Dana, Quincy, and other young fellows" were not ill employed in lengthened discussions of the right of taxation. The repeal of the stamp act gave an opening to practice, in which Mr. Dana was soon much engaged. He was of counsel in the well-known Lechmere slave case in 1769, decided some 3 years before that of Somerset, and to the same effect. In 1773 he acted in behalf of the Rhode Island patriots in concert with John Adams for the prosecution in the matter of Rome's and Moffat's letters; and in the next year opposed, though one of the youngest of the bar, the addresses of that body to Gov. Hutchinson on his departure. In Sept. 1774, he was chosen delegate from Cambridge to the 1st provincial congress of Massachusetts. In the beginning of April following he sailed for England (where his brother had settled), charged with confidential letters to Dr. Franklin on the critical state of affairs, from Warren, the elder Quincy, Dr. Cooper, and other leaders. John

Adams, in a letter of April, 1776, introduces him to Washington as "a gentleman of family, fortune, and education, who has just returned to his country to share with his friends in their dangers and triumphs. He will satisfy you that we have no reason to expect peace from Britain." His connection, through his brother's marriage, with the Kinnairds and the Pulteneys, among whom he also met Gov. Johnstone, enabled him to judge of the state of English feeling beyond the usual American circle there. He was also intimate with Dr. Price, and had contributed to the material of the work published by him, soon after, in defence of the colonies. In the May after his return he was chosen by the Massachusetts assembly one of the council, who at that time acted not only as a senate but as the executive of the state; of this body he continued a member by reëlections until 1780. In Nov. 1776, he was chosen a delegate from Massachusetts to the congress of 1777, which formed the confederation, and again to the congress of 1778, where he was placed at the head of a committee of the first importance and responsibility at that juncture, charged with the entire reorganization of the army and its establishments. Accompanied by President Reed, Gouverneur Morris, and others of the committee, he passed from January to April of that year in the camp at Valley Forge, concerting with Washington the plan subsequently transmitted by congress, June 4, 1778, to the commander-in-chief, "to be proceeded in with the advice and assistance of Mr. Reed and Mr. Dana, or either of them." He was also, with G. Morris and Drayton, of the committee of April 20, 1778, upon whose well-known report the so-called conciliatory bills of Lord North were unanimously rejected, and the intended influence of the peace commission of that year was forestalled and frustrated. His English acquaintance Johnstone was of this commission, and had hoped to secure his coöperation by a letter addressed to him immediately on his arrival; which was, however, laid before congress, July 18, with the more obnoxious overtures to Reed and Robert Morris. On Sept. 29, 1779, Mr. Dana was chosen secretary to Mr. Adams's embassy, to negotiate treaties of peace and commerce with Great Britain, and sailed with the minister from Boston, Nov. 13, in the French frigate Sensible. Landing after a passage of 25 days at Ferrol in Spain, they made a toilsome winter's journey across the mountains, and arrived at Paris, Feb. 9, 1780. Events being not yet ripe for negotiation, and his relations with Vergennes not cordial, Mr. Adams left for the Netherlands, July 27. Mr. Dana remained until Sept. 12, when, upon receiving the commission of congress for Mr. Adams and eventually for himself to raise loans in Europe, he joined that gentleman in Amsterdam, and remained with him in Holland until December following. March 15, 1781, he received in Paris the congressional appointment (of Dec. 18, 1780) of minister to Russia, and leaving that city April 7, again joined Mr. Adams in Holland, where he was detained until July 7, when he proceeded by way of Frankfort and Berlin to his post at St. Petersburg. His powers extended, beside the making of treaties of amity and commerce, to an accession of the United States to the "armed neutrality" of the north. The results of Mr. Dana's 2 years' residence at the court of St. Petersburg are given in detail in Sparks's "Diplomatic Correspondence of the Revolution," vol. viii. His intercourse with Count Ostermann of the foreign office was frequent and friendly, but informal. The influence of England was strong, of France ambiguous or suspected; the policy and perhaps the pride of Catharine promised her the part of mediator between the three powers, which she was no wise disposed to sacrifice to an immediate recognition of American independence; and she maintained her attitude of reserve even after the signature of the preliminaries of peace. Having exhausted every resource that appeared compatible with the dignity of his country, Mr. Dana obtained leave from congress, and quitted St. Petersburg, Sept. 4, 1783, returning direct by ship to Boston, where he arrived in December. To the diplomatic controversy of Mr. Adams with Count Vergennes and Dr. Franklin, Mr. Dana was not a party, but he was a party to the facts out of which it arose. Mr. Adams says in his vindication of his course: "I had the advice and approbation of Chief Justice Dana, then with me as secretary of the legation for peace, to every clause and word in the whole correspondence. He said the 'count neither wrote like a gentleman himself, nor treated me like a gentleman; and it was indispensably necessary that we should show him that we had some understanding and some feeling.'" In Feb. 1784, Mr. Dana was again delegated by the assembly to the general congress, where he took his seat May 24, and on the 29th was selected to represent Massachusetts on the committee of states, which continued in session until Aug. 11, being vested with many congressional powers during the recess. Jan. 18, 1785, he was appointed by Gov. Hancock a justice of the supreme court of Massachusetts. Aug. 29, 1786, he was chosen delegate to the Annapolis convention, which resulted in the call of the convention which framed the constitution of the United States. To this latter body he was also appointed a delegate, April 9, 1787, but his judicial duties and his health, still suffering from his residence at St. Petersburg, prevented his attendance. In the Massachusetts convention, however, for the adoption of that instrument (Jan. 9, 1788), he took a leading part in its favor. Nov. 29, 1791, he was appointed chief justice of Massachusetts, and during his 15 years' tenure of that office kept aloof from political life; unless it should now be considered an exception that he was a presidential elector in 1792 and 1800, as well as in 1808. He was appointed by Mr. Adams, June 5, 1797, with Cotesworth Pinckney and John Marshall, special envoy to the French

republic; but precarious health compelled him to decline that office, which was afterward conferred upon Mr. Gerry. After retiring from the bench in 1806, where he was succeeded by his friend Theophilus Parsons, Chief Justice Dana took no official part in public affairs. The ardent discussion of Mr. Jefferson's embargo throughout the towns of New England, called out his eloquence at Cambridge, where its impression is not yet lost. This was not, however, a partisan opposition, as he had always strenuously resisted the policy of suspending commerce when it had been advocated on earlier occasions.—A succession of such public trusts during 30 years of the first period of the republic attests Mr. Dana's eminent ability and integrity; yet one is additionally struck, in the accounts of his contemporaries, by a peculiar impressiveness of personal character, and an influence out of the common range. As a judge he was well read and apprehensive of principles, and of an exemplary austerity toward all manner of chicane and indirection, a discerning and assiduous diplomatist, and a man of leading in elective and popular assemblies, where his eloquence exhibited a rare union of impassioned feeling with natural dignity. He was one of the founders of the American academy of arts and sciences, and his retirement was enlivened by his interest in enterprises for the benefit of the neighborhood of Boston, and by literary and other cultivated tastes. His house at Cambridge was much visited by his old fellow leaders of the federal party, and by younger men from the university, the Channings, Allston, Buckminster, and others, afterward variously distinguished. He was married in early life to a daughter of William Ellery of Rhode Island, one of the signers of the declaration of independence, and was the father of Richard H. Dana, and several other children.

DANA, James Dwight, LL.D., an American philosopher, born at Utica, N. Y., Feb. 12, 1813, was graduated at Yale college in 1833, having been attracted to that institution by the fame of the elder Silliman. During his regular course of study, Mr. Dana evinced an especial love for the natural sciences and mathematics. Soon after leaving the college he received the appointment of teacher of mathematics to midshipmen in the U. S. navy, and sailed to the Mediterranean in the Delaware ship of the line, returning in 1835. During the 2 years following he acted at Yale college as assistant to Prof. Silliman, whose successor in office he afterward became. In Dec. 1836, he was appointed mineralogist and geologist of the U. S. exploring expedition, then about to be sent to the Southern and Pacific oceans. The squadron, under the command of Com. Wilkes, sailed in Aug. 1838, and returned home in 1842. During the 13 years following, Mr. Dana was engaged in preparing for publication the various reports of this expedition committed to his charge, and in pursuing other scientific labors. He resided at Washington from 1842 to 1844, and then returned to New Haven, where he soon after married Henrietta Frances, daughter of Prof. Silliman, and where he has since resided. Before going to the Pacific he published, in 1837, the first edition of his "Mineralogy," a work of high repute in Europe and America, of which the 4th revised and enlarged edition appeared in 1854. His first publication connected with the observations which he made in the exploring expedition was a "Report on Zoophytes," which appeared in 1846 (740 pp. 4to.), with an atlas of 61 folio plates. In this work, Mr. Dana reviewed the whole department of polyps, combining his own observations with those of earlier authors, and proposed a new classification, bringing, for the first time, the actiniæ and the alcyonoid polyps into their true relations to the astræoid polyps. The number of new species which he describes is 230. The 2d work in the same series was a "Report on the Geology of the Pacific" (756 pp. 4to., 1849), with an atlas of 21 plates. This work presents a view not only of the geology of parts of Australia, western America, and the islands of the Pacific, but also treats at length, and with original views, of volcanic phenomena, coral reefs and islands, and the general features of the globe. The 3d work pertaining to the exploring expedition was a "Report on Crustacea" (1620 pp. 4to. 1852–'54), with an atlas of 96 folio plates. In this work 680 species are described, of which 658 are new. These reports were published by the U. S. government, and only 200 copies of each have thus far been issued. With few exceptions, the drawings in these atlases were made by Mr. Dana himself. While engaged in preparing the last two of these reports, Mr. Dana has been the active editor of the "American Journal of Science and Arts," founded in 1819 by the elder Silliman, and well known as the chief repository of the scientific labors of their countrymen. To this journal, which completed its 76th volume in 1858, as well as to the proceedings of the American academy of arts and sciences in Boston, the lyceum of natural history of New York, and the academy of natural sciences of Philadelphia, Mr. Dana has contributed various important scientific memoirs. A series of 4 articles from his pen, entitled "Science and the Bible," called forth by a work of Prof. Tayler Lewis on the "Six Days of Creation," appeared in the "Bibliotheca Sacra" in 1856–'7. Soon after the resignation by Prof. Silliman of the chair of chemistry and geology in Yale college, Mr. Dana entered, in 1855, on the duties of the office of Silliman professor of natural history and geology in that institution, to which place he had been elected in 1850; his brother-in-law, Prof. Benjamin Silliman, jr., having been appointed to the chair of chemistry. Prof. Dana is now engaged in discharging the duties of his professorship, and in editing the "American Journal of Science." A text book on geology from his pen has been announced as nearly ready for

publication. In 1854 he was elected president of the American association for the advancement of science, having been for many years one of the standing committee of that body, and in Aug. 1855, he delivered the annual address before that association at its meeting in Providence. Prof. Dana has been elected a member of various learned societies in Europe, including the royal academy of sciences in Berlin, the royal academy of sciences in Munich, the geological and Linnæan societies in London, the philomathic society in Paris, and others.

DANA, James Freeman, an American chemist, born in Exeter, N. H., in 1793, died in the city of New York in 1827. He was the son of Luther Dana, an officer in the American naval service in the revolution. He was graduated at Harvard college in 1813, studied medicine with Dr. Gorham of Boston, spent 6 months in London in the study of chemistry under the instruction of the celebrated Accum, and on his return was employed to refit and refurnish the laboratory of Harvard college, and established himself in Cambridge as a physician, holding also the office of assistant to the professor of chemistry. In 1819 he was appointed professor of chemistry in the medical school of Dartmouth college, where he lectured also on mineralogy and botany. In 1825 he was chosen professor of chemistry in the New York college of physicians and surgeons, which office he held at the time of his death. His only considerable publication was a small work on the "Mineralogy and Geology of Boston and its Vicinity," written in conjunction with his brother, Dr. S. L. Dana.

DANA, Richard, an American jurist, born at Cambridge, Mass., July 7, 1699, was graduated at Harvard college in 1718, died May 17, 1772. He was a grandson of Richard Dana, the first of the family who came from England and settled at Cambridge in 1640. After practising law for a time at Marblehead and Charlestown, he removed to Boston, where he became a leading barrister. Judge Story, in his work on American precedents, has taken more examples from him than from any other pleader, except Judge Trowbridge. In the obituary notices of him he is spoken of as at the head of the bar. He was more generally distinguished for his prominence in the measures of resistance which immediately preceded the revolution. His age already advanced, his office of magistrate and position at the bar and in society, and the intrepidity of his character, carried great weight to the side of his young patriot friends. Although devoted to his profession and declining office, he was a leading figure in those important political assemblages, where he sometimes presided, the Boston town meetings from 1763 to 1772. It was the custom of Boston in those troubled times to address the country at large on public affairs under the form of published instructions to the representatives of the town. Warren, Hancock, and the Adamses were on committees for this purpose. Mr. Dana was always a member, and often at their head. He reported the papers of Nov. 20, 1767, and May 8, 1770, noted at that time. He was a member of the association of the sons of liberty, and at their celebrated meeting of Dec. 17, 1769, administered to Secretary Oliver the oath of non-execution of the stamp act, and made and signed a solemn official record of that fact, by which he would seem to have exposed himself to the charge of treason under the constructions of those days. His death, which occurred 3 years before the battle of Lexington, is spoken of in the letters of the leading patriots as a great loss to the cause. He was married to the sister of Judge Trowbridge, and was the father of Chief Justice Francis Dana.

DANA, Richard Henry, an American poet and essayist, born at Cambridge, Mass., Nov. 15, 1787. He entered Harvard college in 1804, where he remained 3 years, but did not graduate, being involved in the noted rebellion of the classes in 1807. He passed the next 2 years at Newport, R. I., in completing the usual collegiate studies. He read law partly with his father, Chief Justice Dana, and partly in Boston, and was admitted to the bar there in 1811, and afterward, with a view to practising in the latter city, to the bar of Baltimore, after an additional short term of study. He returned in the winter of 1811–'12 to his native town, where he entered upon his profession, and was for a time also warmly interested in politics, on the federal side, as a member of the legislature and otherwise. His paramount tastes, however, were literary, and he joined in 1814 the club of gentlemen in Cambridge and Boston by whom the "North American Review" was projected and for a time conducted. His earliest writings were published in that periodical, the "Essay on Old Times," and an article upon the poems of Washington Allston, afterward his brother-in-law. In 1818–'19 he was associated with Prof. E. T. Channing in the editorship of that review, which subsequently passed to Mr. Edward Everett. His criticisms at that time excited much attention, perhaps as much surprise, and even some indignation. It was then believed that Pope was the touchstone of English poetry; the Elizabethan writers were in less esteem, while Wordsworth and the names associated with his were a matter for jest. The ethics and educational system of the Edgeworths were also in fashion. Mr. Dana expressed a very different opinion on these subjects. In 1821–'22 he published in numbers the "Idle Man," with some aid from his friends Bryant and Allston. It was read and admired by a class of literary men, but this was too small a public for its continuance. His first pieces in verse, the "Dying Raven" and the "Husband and Wife's Grave," appeared in the "New York Review," in 1825, then edited by Mr. Bryant. In 1827 he ventured the "Buccaneer and other Poems" in a small volume. This was well received, indeed highly commended by the critics, and for a volume of American poetry at that day was not unsuccessful. Wilson's praise of the "Buccaneer" in "Black-

wood's Magazine," as "the most powerful and original of American poetical compositions," was perhaps not without an effect on the already changing tendency of poetical taste in this country. In 1833 he published an enlarged volume, including new poems and the papers of the "Idle Man;" and again in 1850, "Poems and Prose Writings," in 2 vols., in which to the contents of the former volume are added poems, the essays and reviews from the "North American Review," and others of a recent date; being a complete collection of his writings, with the exception of a series of 8 lectures upon Shakespeare, prepared at the instance of his cousin, Dr. Wm. Ellery Channing, and delivered with marked appreciation before the best audiences in Boston, New York, and Philadelphia. In the controversy between the Unitarian and Trinitarian Congregationalists of Massachusetts, in 1825–'35, Mr. Dana took an active part with the latter. For many years past, however, he has been connected with the Episcopal church. He resides in Boston, and at a beautiful summer retreat on the shore of Cape Ann.—The success of Mr. Dana as an author is, perhaps, more noteworthy for its quality than its extent. His peculiar style is most highly appreciated by lovers of the simple and masculine beauties of the older English writers. In dealing with the greater passions, the handling is bold, and the language instinctively true, but the manner is dramatic, not melodramatic, nor what is called popular. His vein of sentiment has a charm for meditative minds, and though in a new country, his thoughts turn singularly toward whatever has been consecrated by reverence or the touch of time. The influence of his critical principles is often observable in that order of minds which form the minds of others, and has thus been greater in the literature of the country than may at first appear.

DANA, Richard Henry, jr., an American advocate, son of the preceding, born at Cambridge, Mass., Aug. 1, 1815, was graduated at Harvard college in 1837. Being compelled to interrupt his collegiate course, in 1834, by a weakness of the eyes, he made the voyage described in his "Two Years before the Mast," to California, then a wild and almost unknown region. He was a member of the Dane law school from 1837 to 1840, under Judge Story and Prof. Greenleaf, and during 2 years of that time also acted as adjunct to Prof. Channing in the department of rhetoric at the university. He was admitted to the Boston bar in 1840, and was directly much employed in the admiralty courts, having been naturally led to pay special attention to maritime and commercial law. In 1841 he published a manual of sea usages and law, "The Seaman's Friend," republished in England as the "Seaman's Manual." A letter published by him at the time of the melancholy affair of the U. S. brig Somers, 1843, and in detailed explanation of the critical position of the officers on that occasion, served to moderate the natural public feeling, and rendered it more favorable to Capt. Mackenzie. Mr. Dana's practice gradually became general in the law courts, where he is now one of the leading advocates, and has been engaged in a larger than usual proportion of causes of public interest; among others, in the well-known reinvestigation of the presumption of murder from homicide (York's case, 1845), which has led to new enactments on the general subject in several states; on the legal right to require the use of the Bible in the common schools in Maine (Donahoe *vs.* Richards, 1854); on the canon law of the Episcopal church, in the Rev. Mr. Prescott's cases, 1852; on the title to public and religious charities, in the case of the Presbyterian synod *vs.* the parish of the late Dr. Channing, 1854; in the numerous trials for the rescue of the slave Shadrack in 1853, and in the still more noted case of Anthony Burns in 1854. He appeared, however, voluntarily in 1855, against the removal of Judge Loring in the then state of the law, but not after the Massachusetts statute of May 21, 1855, under which the removal eventually took place. Mr. Dana has not been a candidate for office, but his political course has been one of some mark. He was one of the founders of the free-soil party, a delegate from Boston to the Buffalo convention of 1848, and a popular speaker in that and the republican movement of 1856. He was one of the ablest members of the Massachusetts constitutional convention of 1853, and his speeches in that body have received high praise in the chief work of an eminent foreign publicist (Mohl's *Geschichte und Literatur der Staatswissenschaften*). The "Two Years before the Mast," by which Mr. Dana is so well known, is the ship and shore life of a common sailor detailed from personal experience by a man of education. It gained at once both in America and England a popularity that may be compared to that of "Robinson Crusoe." It is also a trustworthy authority on a subject of some importance, the distinctive character of the American merchant service. Mr. Dana has been for many years a member of the Episcopal convention of the diocese of Massachusetts, and taken a leading part in its proceedings. He has published biographical sketches of the lamented Major Vinton, and of his relatives, Prof. Channing and Washington Allston, prefixed to posthumous volumes of their writings. He has also occasionally contributed to the "North American Review" and the "Law Reporter."

DANA, Samuel Luther, an American chemist, brother of James Freeman Dana, born at Amherst, N. H., July, 1795. He was graduated at Harvard college in 1813, while war raged between the United States and Great Britain. He was desirous of becoming a military engineer, solicited the appointment of a cadet to enter West Point, and was immediately commissioned a lieutenant in the 1st regiment U. S. artillery, and served both in New York and Virginia, until the close of the war. He was retained on the peace establishment when the army was disbanded, but resigned his commis-

sion in June, 1815. He immediately commenced the study of medicine, and received the degree of M.D. in 1818. Practising as a physician from 1819 to 1826, in Waltham, Mass., he was in daily friendly intercourse with those able and enterprising men who founded the cotton manufacturing industry of the state; and having established on his own account a chemical laboratory for the manufacture of oil of vitriol and bleaching salts, he founded the "Newton Chemical Company," of which he was the chemist till 1834. He then accepted the appointment of resident and consulting chemist to the Merrimack manufacturing company, the duties of which office he still performs. In his first work he was associated with his brother, Prof. James F. Dana, in publishing the "Mineralogy and Geology of Boston and its Vicinity" (1818). His next publication, made while he was in England in 1833, was a clear exposition of the chemical changes occurring in the manufacture of sulphuric acid. This was followed by a report to the city council of Lowell, on the danger arising from the use of lead water pipes. About this period, although the responsible duties of his position absorbed the principal portion of his time, the experiments and observations which have connected his name with agricultural science were made, and the original materials obtained for the "Farmers' Muck Manual," published in 1842. In 1843, "An Essay on Manures" was honored by the prize of the Massachusetts agricultural society, and has been printed in successive editions, while his labors in connection with the agricultural and geological reports of the state survey have been gratefully acknowledged. The translation and systematic arrangement of the treatise of Tanquerel on lead diseases, was a contribution to medical knowledge most earnestly called for, and most important in its influence. The discussion of the lead pipe question gave rise to several papers and pamphlets from Dr. Dana's pen. He has also contributed several papers to the "North American Review," and other periodicals. His investigations have shed light on the more obscure points of the important art of printing cotton, and led to many improvements. His discoveries in connection with bleaching cotton were first published in the *Bulletin de la société industrielle de Mülhausen*, in several papers, as correspondence with that society. The principles there established have led to the American method of bleaching, of which that acute practical chemist Persoz, in his *Traité de l'impression des tissus*, says "that it realizes the perfection of chemical operations." (See BLEACHING.)

DANAË, in Greek mythology, the daughter of Acrisius, king of Argos, and mother of Perseus. An oracle had predicted that a son of Danaë would one day kill Acrisius, and the latter, in order to prevent the fulfilment of the prophecy, shut up Danaë in a brazen tower. But Jupiter was enabled to visit her by transforming himself into a shower of gold, and descending through the roof of the tower, and Danaë gave birth to a son. Seeing his designs thus thwarted, Acrisius placed the mother and child in a chest, and cast them into the sea. But Jupiter watched over their safety, and wafted them to the island of Seriphus, where they were kindly received by King Polydectes. Perseus grew up, and did afterward actually kill his father by an accident. Another legend relates that Danaë went to Italy, where she became the mother of Daunus, the ancestor of Turnus, who was king of the Rutuli when Æneas arrived in Italy.

DANAIDES, according to the Grecian legend, 50 daughters of Danaus. They were married to the 50 sons of their uncle Ægyptus, and their father, who was in dread of Ægyptus and his sons, made them promise to murder their husbands on their wedding night. This promise they all fulfilled except Hypermnestra, who spared her husband Lynceus. For their punishment they were condemned, in Hades, to fill sieves with water.

DANAUS, a mythical personage in Grecian story, son of Belus, and twin brother of Ægyptus. He had received from his father the kingdom of Libya; but fearing Ægyptus, he fled to Argos, where he became king. According to one legend, he was afterward killed by his nephew Lynceus, the only one of the sons of Ægyptus who escaped death at the hands of his wife.

DANBURY, a post town, and one of the capitals of Fairfield co., Conn.; pop. of the whole township in 1850, 5,964. It is a handsome town, built principally on one street, over a mile in length, and beside the county buildings contains 7 churches, 2 banks, a savings bank, a printing office, 4 fulling, 5 grist, and 15 saw mills, numerous hat factories, and 3 comb factories. The Danbury and Norwalk railroad and Still river, a good mill stream, flowing into the Housatonic, pass through it. Value of real estate in 1857, $1,827,161. In 1777 it was attacked and burned by the British, on which occasion Gen. Wooster, the American commander, was killed. Incorporated in 1696.

DANBY, FRANCIS, a British painter, born at Wexford, Ireland, Nov. 16, 1793. Among the best known of his early pictures are "Christ Walking on the Sea," "Cleopatra setting out to meet Anthony," the "Opening of the Seventh Seal," &c. His later works are more familiar to the general public through the medium of the illustrated art journals. Such are the "Ship on Fire," "Departure of Ulysses from Ithaca," "Caius Marius among the ruins of Carthage." Mr. Danby has 2 sons who are also painters.

DANCE, GEORGE, an English architect, died Feb. 8, 1768. As architect to the corporation of London, he built the mansion house in 1739–'40. He was also architect of St. Botolph's, St. Luke's, and other churches in London.—GEORGE, jr., son of the preceding, born in 1740, died Jan. 14, 1825, was the architect of the prison of Newgate and of St. Luke's hospital. In 1789 he erected the front of Guildhall. Among his minor works are the British institution, Pall-mall, and the theatre at Bath. He was one of

the earliest members of the royal academy, and professor of architecture. He published a series of portraits of artists and public characters in 1811–'14, engraved by William Daniell, R. A., after the original drawings.

DANCE OF DEATH (Lat. *chorea machabæorum*; Fr. *danse macabre*, and *danse des morts*; Ger. *Todtentanz*), a mediæval religious dance, long a favorite subject of painting and poetry, in which persons of all ranks and ages were represented as dancing together with the skeleton form of death, which led them to the grave. The gaunt and stalking anatomy, in which Gothic imagination personified death, was treated both by the poets and populace of the 14th century with mingled humor and seriousness. Masked figures representing it appeared during carnival, with the privilege of taking by the hand and dancing with whomsoever they might meet. With the approbation of the clergy, a sort of masquerade was instituted, which was performed in the churches, in which the chief characters in society from the pope to the beggar were supported, dramatic conversations being intermingled between death and the persons in the procession, each of whom in turn vanished from the scene, as a symbol of departure from life. This custom, as represented by art, appears for more than 3 centuries in a vast number of forms, most various in pathos, humor, and grotesqueness; in verse in nearly every European language; and in paintings on town halls, in market places, in the arcades of burying grounds, and on the walls of palaces, cloisters, and churches. One of the most interesting poems on the subject is in Spanish, the *Dança general de los muertos* (found entire in the appendix to Ticknor's "History of Spanish Literature"), which belongs to the 14th century, and in which death summons to his mortal dance first the pope, then the cardinals, kings, bishops, and so on, down to day laborers. Each makes some remonstrance, but in vain, "for still the cry is, haste! and haste to all." Jacques Jacques, a facetious canon of Ambrun (1658), gives a collection of the useless excuses which were offered, and makes death exclaim: "Were I not absolute over them, they would confound me with their long speeches; but I have business, and must gallop on." Poetical inscriptions often accompanied the paintings, which are first traced in the south-western parts of Germany, in Switzerland, Alsace, and Swabia, the oldest being that in a convent of Basel, which, according to the inscribed verses, was painted in 1312, and was renewed probably in the 16th century. Among the most celebrated dances of death are those of the cloister of the Dominicans at Basel, painted in 1480 and often renewed, of the palace of St. Mary at Lübeck, in the castle and cemetery of Dresden, at Lucerne, Anneberg, Leipsic, Strasbourg, and Rouen, in the church of the innocents at Paris, in the church of *La chaise Dieu* in Auvergne, in the crypts of the church of St. Michel at Bordeaux, in the cathedral of Amiens, in the church of St. Paul in London, to which John Lydgate added verses that were translated from the French, in the palace of St. Ildefonso in Spain, and the famous painting of the *Trionfo della morte* in the *campo santo* of Pisa, by Andrea Orcagna, in the 14th century. Many of these have been preserved in engravings, are found on missals and on the margins of numerous old books, and in the 16th century were reproduced in miniature as ornaments for the sheaths of swords and poniards. The fresco at Basel was destroyed by the falling of the walls in 1805, only fragments of it being preserved, but in the 16th century it suggested to Holbein his celebrated series entitled the "Dance of Death," which combines 53 distinct and most diverse scenes. Death here assumes various ironical costumes, while meeting with and overcoming persons in every condition of life. The older pictures are not divided into single scenes, but the skeleton appears leading after it a procession of all ranks and ages. All of the poems and paintings on this grim subject are of a mingled sublime and grotesque character, betraying a sentiment of profound sadness beneath a gay and ironical manner. The best works treating of it are Massmann, *Literatur der Todtentänze* (Leipsic, 1841), *Baseler Todtentänze* (Stuttgart, 1847); Peignot, *Recherches sur la danse des morts* (Dijon and Paris, 1826); Langlois, *Essai historique, philosophique, et pittoresque sur les danses des morts*, with 54 engravings (2 vols., Rouen, 1852); and Douce, the "Dance of Death" (London, 1833).

DANCING (Ger. *tanzen*, Fr. *danser*, to dance), the art of rhythmical movement, consisting of steps, bounds, and inclinations of the figure, usually performed to the cadence of music. Though the feet, by which the body changes from place to place, are the principal agents in dancing, yet all the slight wavy motions of the bust, head, and arms are also to be considered, since it is by the harmony of all the movements that dancing becomes a thing of beauty and art. Especially when several persons join in the dance, the most diverse postures and motions have a general symmetry, so that the dancing group presents an æsthetic unity. Dancing is perhaps the oldest and most universal of the fine arts, and has been in vogue for various purposes, in greater or less perfection, from the earliest times, equally among savage and civilized nations. Among the ancient Egyptians, it was both a social recreation and a religious exercise. Persons of high rank did not, however, indulge in it either in public or private assemblies, but employed professional dancers, like the almeh and ghawazee of the present time, who obtained a livelihood by performances in wealthy houses. A modern Asiatic ambassador once remarked to his European host: "You are then very poor, since you are obliged to dance yourselves." The object of Egyptian dances was to exhibit a great variety of graceful gestures and attitudes. They followed the music of the harp, lyre, guitar, pipe, tambourine, or drum, or even the clapping of hands or snapping of fingers; many of their

postures resembled those of the modern ballet; and the *pirouette* seems to have been a favorite in Egypt 4,000 years ago. There was a figure dance common throughout the country, in which two partners advanced toward each other, stood face to face upon one leg, and having performed a series of movements, retired in opposite directions, continuing to hold each other by one hand, and concluding by whirling each other around. The costume of the female dancers was a flowing and ornamented robe, reaching to the ankles, and of the finest texture, so as hardly to conceal the figure. The Egyptians danced also at the temples in honor of the gods, some of their sacred dances being mysterious imitations of the celestial movements and of the harmony of the universe. The Hebrews also introduced dancing into solemn festivities, especially on occasions of triumph and pleasure, the Hebrew word for dance meaning literally to "leap for joy." The description given of Miriam who took a timbrel in her hand, while all the women went out after her with timbrels and with dances, applies to many modern oriental dances, led by a principal person, whose steps, gyrations, and songs, often extemporaneous, are skilfully imitated by the group of attendants. Both sexes bore a part in the Hebrew dancing processions, but always remained in separate companies. In Babylon the worship of Astarte was celebrated by the dances of maidens in the temples; and a Persian dance is mentioned whose movements, performed to the music of the flute, consisted in dashing crescent-shaped shields together, falling upon the knee, and rising again. In India the most ancient sacred writings mention the bayaderes, or dancing girls, whose performances are still indispensable in religious and social festivities, and whose style of dancing, unlike that of the ballet, consists in but slightly raising the feet and in expressing vehemence of passion by the eyes and by gliding and waving movements of the neck, bust, and arms. The dancing girls of Java are painted entirely white, and though they move their feet but slightly, they keep their arms and the upper portion of their body in so ceaseless and rapid circular and undulatory motion that it is impossible for the eye to distinguish any definite outlines to their figure.—In Greece dancing formed a part of the education of youth, and was included with song and poetry in the wide sense of music. It was in high esteem from the heroic ages, was connected with nearly every religious ceremony, and skilful dancers sometimes were honored with golden crowns, and had statues erected to their memory. The strophes and antistrophes of odes are supposed to owe their origin to the alternate movements of different parties of dancers, and the dramatic chorus probably consisted at first of all the population of a city meeting in a public place, and worshipping the gods by hymns and dances. Plato thought that all dancing should be of a religious character, and should be an object of legislative care, as being essential to grace of motion. The Greek religious dances, excepting the Bacchic and corybantian, were very simple, consisting of gentle inclinations of the body and a gliding promenade around the altar. The Bacchic dance, representing the adventures of the god Dionysus, was common throughout Greece, forming a principal part of the Bacchanalian festivities; and the most illustrious men in the state combined with persons representing satyrs and titans, and with husbandmen, in performing it. The corybantian dance, known chiefly in Crete and Phrygia, was of the wildest character, the performers being armed and dashing together their swords and shields with extravagant fury. Greek dancing was a gymnastic and military as well as a mimetic and religious exercise. The Pyrrhic dance, which existed from the mythical age, is described by Plato as representing by rapid movements of the body the ways of avoiding strokes of the javelin and sword, and the mode of attacking an enemy. It was remarkable for somersets, tumblings, and swift evolutions in the midst of projecting daggers and drawn swords, and seems to have surpassed in skilful escapes any thing known in modern times. Tacitus mentions that the German youths were taught to dance amid swords and spears pointed at them. Prof. Wilson, who was a most accomplished athlete, is recorded to have mounted one of the tables at a festival in commemoration of Burns, and to have danced a *pas seul* among the wine glasses and decanters, without causing any fracture; but this precarious mode of dancing has rarely been cultivated in modern times, except by professional artists. In many of the Greek states dancing was carried to great perfection by the *hetæræ*, who were often admitted to divert the guests at the close of a repast.—Dancing among the Romans was at first most strictly connected with religion, and it was always deemed dishonorable for a Roman citizen to take part in other than religious dances. During the latter years of the republic this art was even deemed unworthy of a free man, and Cicero affirmed that it was rare for any one to dance who was not either intoxicated or a fool. But under the empire the pantomime and mimetic dances attained a high degree of perfection. The performers were in such esteem that when at the approach of famine the emperor Constantius banished all philosophers from Rome, he retained more than 3,000 dancers. Lucian, in his dialogue on dancing, maintains that the mimetic dancer should be familiar with poetry, geometry, music, and even philosophy; he should be a good rhetorician to express the passions of the soul, and a good painter and sculptor to reproduce attitudes and countenances; he should rival Chalcas in knowing the present, past, and future, and Thucydides in the sense and observation of decorum; he should be inventive, judicious, with a delicate ear, a quick sensibility, and a firm and supple body; in short, it would seem that he should be the most perfect of men.—In the early centuries of the church, the dance was sometimes united

with the hymn in Christian festivities. According to Scaliger, the first bishops were styled *præsules*, because they led the dance. Pious dances were customary in the churches till at least the 12th century. Banished at length from the sanctuary as according ill with the gravity of the sacred mysteries, they were still perpetuated till the 17th century in Spain, Portugal, and some other Catholic countries. Cardinal Ximenes permitted devotional dancing in church at Toledo; the Jesuit Menestrier related in 1682 that it was not then uncommon for the clergy to dance in the churches with the children on Easter day; and within a century, at Limoges, the people and clergy have danced together around the choir of the church of St. Leonard on St. Martial's day. The baladoir dances were early combinations of pagan ceremonies with Christian festivities, which were censured by Pope Zacharias in 744, but 3 of which (the May dance, the dance of Saint John, and the torch-light dance) remained in France throughout the middle ages as frenzied and extravagant processions, in which crowds of people, sometimes nearly naked, but crowned with flowers, marched hand in hand through the streets and churches, singing, dancing, and gambolling with such fury that only a resort to exorcism could check them. The ambulatory dances, many of them of Portuguese origin, were mediæval allegorical processions, such as those of the famous feasts of fools and of asses, presenting often a rude spectacle of the principal scenes in the life of Christ. With such solemnities the canonization of Cardinal Borromeo and the beatification of Ignatius Loyola were celebrated, the theme represented on the latter occasion being the siege of Troy.—The Mohammedan religion forbids both dancing and music, not only in the mosques, but even within the harem. It is only by special permission obtained at Constantinople that the master of a house is released from this law. Dancing is not one of the pleasures of paradise promised by the Koran. The dervises, celebrated for their fantastic dances, whirling upon their feet with extraordinary rapidity, sometimes holding lighted coals in their teeth, are condemned by the law and reproved by religion. The modern Christian sect of Shakers make their worship consist largely in dancing, which was originally of a violent and irregular character, abounding in leaps and shouts, but is now a simple and uniform movement around the hall of worship to the music of a hymn and of clapping of hands.—In the 14th century the dance, banished from the cities, took refuge in the country and became the delight of peasants, who were excluded from the chivalric diversions of the nobles. In this way originated the picturesque rural dances, which in the next century were borrowed by the courts of Italy and France. Thus at the marriage of Charles VI., 6 mountaineers from the Pyrénées were introduced to perform one of their native dances; and at the festival given by Catharine de' Medici to the duke of Alva at Bayonne there were troops of shepherds and shepherdesses, each of which executed the dances peculiar to their own district. Among the dances which have been successively favorites in France from the 16th to the 19th century are the *branle*, consisting of several persons joining hands, leaping in circles, and keeping each other in continual agitation; the minuet, introduced from Spain under the auspices of Catharine de' Medici, and of a slow and grave character; the *pavane*, also of Spanish origin, proud and stately as a hidalgo, in which the performers looked upon each other strutting like peacocks, and in which Margaret of Valois excelled; the *gaillarde*, a Neapolitan dance, of livelier movement than the preceding; the *gavotte*, which Marie Antoinette preferred and danced excellently, which was modulated to a quicker air after the Terror, was performed by two persons only, and abounded in salutations and reverences; the waltz, which was introduced by the triumphant soldiers of Napoleon from Germany; the *contre danse*, the country dance of England, which dethroned the minuet in France, by which Trenitz gained his successes in the *salons* of the consulate, and which after a long reign has but recently ceased to be *à la mode;* and the *galop* or *galopade*, the most rapid of dances, which had its origin in Hungary, made its first appearance at Vienna or Berlin about 1822, was introduced into France at the balls given by the duchess of Berry during the carnival of 1829, and which is famous as the furious and dishevelled gallop which terminates the masked balls at the French opera, and which Auguste Barbier has stigmatized in his verses. Other dances, once peculiar to particular districts, but most of which are now cosmopolitan, are the Scottish jig, the Portuguese *modinha*, the Spanish *bolero*, *fandango*, *jota*, and *cachuca*, the Basque step, the impetuous *farandole* of Languedoc, the polka, *mazourka*, *redowa*, and *cracowiak*, borrowed from the peasants of various Slavic countries, the cotillon by which Lauzun made his singular fortune, the schottisch which Cellarius made popular, and the simple *ronde*, the French national dance, by which the peasants celebrate annually the gathering of the harvests, and which is esteemed a symbol of union and strength. The gypsies are favorite dancers in Spain, and they render the *ole*, the *jaleo de Xeres*, and the *fandango* with inimimitable grace and passion. The *ole* especially delights the vehement Andalusians, and its charm consists in its rapid combinations of the most various motions, while the vivid gypsy eye glaring with delirium of transport holds the spectators entranced. The *fandango* is a love scene, consisting of successive approaches by the *danseur*, and retreats by the *danscuse*, till at last, tired of the contest, both parties approach, at first with hesitation, and then rushing with eagerness. Many of the Spanish dances are of an indelicate character, and are prohibited from the public stage. Fanny Elssler was forbidden in some of the cities of

Europe to dance the *jaleo de Xeres*. Dancing exists among all savage peoples which travellers have visited, and negroes on the African coast have been said to throw themselves at the feet of a European playing on a fiddle, and to beg him to desist unless he would tire them to death; for while he played they could not cease dancing. Dancing was one of the principal amusements of the American aborigines, being more common among them than in any civilized society. It entered into their forms of worship, their martial celebrations, and their mode of entertaining strangers of distinction. The term scalp dance designates a custom, prevalent especially among the Sioux, of dancing for 15 nights in succession around the scalps brought back by a war party. They dance in a circle, with their heads adorned with ostrich feathers, leaping, yelling, brandishing their weapons, boasting their prowess, distorting their faces, and imitating all the fury of battle. This celebration is usually by night, by the light of blazing torches. Young women may assist by chanting in chorus, or by standing in the centre of the ring, but are rarely permitted to join in the dance. (See also BALL and BALLET.)

DANCING DISEASE, or TARANTISMUS, an epidemic nervous affection, apparently allied to chorea, occasionally prevalent in Italy and other countries in the south of Europe. It was long supposed to be caused by the bite of a large spider, the *aranea tarantula;* but as scarcely any of those affected with it had any consciousness of having been bitten by a spider or any other insect, and as it has been in every instance propagated mainly by physical contagion, like chorea, demonomania, and other kindred affections, there is every reason to believe it originated from the same causes. The tarantismus was first noticed in the 15th century, a period rife with cerebral and nervous affections, and is thus described by Baglivi: "When any are stung (or attacked with the disease), shortly after it they fall upon the ground, half dead, their strength and sense going quite from them. Sometimes they breathe with a great deal of difficulty, and sometimes they sigh piteously; but frequently they lie without any manner of motion, as if they were quite dead. Upon the first sounding of music the forementioned symptoms begin slowly to abate; the patient begins slowly to move his fingers, hands, feet, and successively all parts of the body, and as the music increases their motion is accelerated; and if he was lying upon the ground, up he gets (as in a fury), falls a dancing, sighing, and into a thousand mimic gestures. These first and violent motions continue for several hours, commonly for 2 or 3. After little breathing in bed, where he is laid to carry off the sweat, and that he may pick up a little strength, to work he goes again with as much eagerness as he did before, and every day spends almost 12 hours by the clock in repeated dancing; and, which is truly wonderful, so far is he from being wearied or spent by this vehement exercise, that, as they say, it makes him more sprightly and strong. There are, however, some stops made; not from any weariness, but because they observe the musical instruments to be out of tune; upon the discovery of which one could not believe what vehement sighings and anguish at heart they are seized with, and in this case they continue till the instrument is got into tune again, and the dance renewed. This way of dancing commonly holds 4 days; it seldom reaches to the 6th." Other observers speak of those affected with tarantismus as howling like dogs, leaping, running wildly about, stripping themselves of their clothing, expressing a like or dislike for particular colors, "and never better pleased than when soundly drubbed on the breech, heels, feet, or back." The attack was frequently followed by melancholy, the lypemania of the medical writers, under the influence of which those affected sought solitary and deserted places, graveyards, and the like, and there remained for several days. Music, generally on the guitar, violin, or dulcimer, was the established prescription for the disease. The dancing mania was very likely to recur at the anniversary of the attack.

DANDELION (Fr. *dent de lion; leontodon taraxacum*, Linn.), a well-known plant, with a perennial root and bitter milky juice, the leaves of which when blanched are used as a salad; the root also is sometimes roasted, and used as a substitute for coffee, or to adulterate that substance. Under cultivation, the plants are forced to extraordinary size, to vend in the spring for a popular and much esteemed pot herb under the name of greens. In medicine, the expressed juice, especially of the root, is employed for its aperient, detergent, and strongly diuretic properties, and should be used while fresh. The flowers of the dandelion are very conspicuous in the meadows and grassy fields in early spring, and are hailed as the harbinger of warm weather and returning heat in the north. The common and generic names, both meaning lion's tooth, were given from a fancied resemblance of its single florets.

DANDINI, the name of a family of Florentine painters: CESARE, born in 1595, died in 1658; VINCENZO, brother of the preceding, born in 1607, died in 1675; PIETRO, a son of Cesare, born in 1646, died in 1712, an artist of considerable genius, who had a peculiar talent for imitating the works of the old masters, particularly those of the Venetian school; and OTTAVIANO, a son of the preceding.

DANDOLO, ENRICO, doge of Venice, member of a patrician Venetian family, which traced its origin to the Roman era, born about 1110, died June 1, 1205. He served the republic in many capacities, and at one time was sent as ambassador to Constantinople. His high rank did not, however, protect him from outrage, and at the command of Manuel Comnenus, he was nearly deprived of sight by having his eyes burned with hot irons, applied, as some historians relate, by the emperor himself. He

was appointed doge in 1192, when he was above 80 years of age, but he still retained all the fire and vigor of youth. During the 4th crusade, the French barons, under Baldwin of Flanders, applied to Venice for aid. After some delay, the doge himself urging the suit of the French ambassadors, the necessary ships were supplied on condition of 85,000 marks of silver, about $850,000, being paid down before the expedition set sail. Great difficulty having been experienced in raising all the money, it was proposed to capture and pillage Zara, a city on the Adriatic which had refused to join the league. Zara was accordingly taken and sacked, and the booty proving amply sufficient for all expenses, the expedition, diverted from the real object of these religious wars, vengeance against the infidel, set sail for Constantinople, on the pretext of enabling young Alexis Angelus to restore his father, the rightful emperor, who had been deposed by his own brother. The city was defended by immense fortifications, by deep fosses and strong walls, by massive chains stretched across the harbor, and by 478 towers placed in a circumference of 18 miles. The aged doge, displaying the gonfalon of St. Mark's, animated his followers, the city was taken, the usurping emperor fled, and the rightful monarch was restored. But when he and his young son were treacherously murdered, and the patriarch of Constantinople driven into exile, the city was again taken and given up to pillage (1204). Dandolo died the following year, and was buried beneath the dome of St. Sophia.—There were 3 other doges of the same family: Giovanni, who reigned from 1279 to 1289; Francesco, from 1328 to 1339; and Andrea, from 1343 to 1354. The last incurred the jealousy of the Genoese by his endeavor to establish commercial relations between Venice and Egypt. Hostilities arose between the 2 states, and, in concert with the Byzantine emperor and Aragon, Dandolo destroyed the Genoese fleet at Cagliari (Aug. 29, 1349). Giovanni Visconti, the new ruler of Genoa, sent Petrarch as ambassador to Venice to negotiate for peace; but, notwithstanding the friendly relation that existed between the poet and the doge, Andrea anew declared war against Genoa in 1354, shortly before his death. He was also one of the earliest historians of Venice. He left a Latin chronicle which comprises the history of Venice from the earliest times to 1342, and compiled a portion of the Venetian laws. A new edition of the *Liber Albus*, treating of the relations of Venice with Turkey, and of the *Liber Blancus*, treating of those with the states of Italy (both based upon the chronicles and code of laws left by Dandolo), appeared in Germany in 1854.

DANDOLO, Vincenzo, an Italian chemist, and for a short time governor of Dalmatia, but not a member of the above family, born in Venice, Oct. 26, 1758, died there, Dec. 13, 1819. After completing his studies at the university of Padua, he established himself as chemist in his native city. His principal work, "Fundamental Principles of Physical Chemistry, applied to the Formation of Bodies and to Natural Phenomena," appeared in 1796, and passed through 6 editions. At the outbreak of the revolution, he was one of those who were deputed by the people to solicit Bonaparte's protection; but by the treaty of Campo Formio, Venice fell into the hands of Austria, and Dandolo, rather than render allegiance to this power, established himself at Milan, which at that time became the capital of the Cisalpine republic. In 1799, when the Russians invaded the town, Dandolo betook himself to Paris, where he published a philosophical work on the regeneration of mankind. Afterward he devoted himself to agricultural and industrial pursuits near Milan; and on Napoleon's annexing Dalmatia to his kingdom of Italy, he appointed Dandolo governor of that province, over which he presided until 1809, when it was allotted to Illyria. He then returned to Venice, with the title of count conferred upon him by the French emperor, and ceased to take any further part in public affairs except in 1813, when he coöperated in quelling the insurrection which had broken out in a neighboring district. Dandolo translated many of the leading French chemical works into Italian, and, apart from his original productions on the same science, conferred a great service upon Italian silk industry and œnology, by his works on the silkworm and Italian wines.

DANE, a S. co. of Wis.; area, 1,235 sq. m.; pop. in 1855, 37,714. The surface is moderately hilly, and the soil calcareous and fertile. In the central part lie some sheets of water called the Four Lakes, the largest of which is 6 m. long. They are connected by short channels, and have their outlet through Catfish river. In the western part of the county is a hill about 1,000 feet high, called Blue Mound. The greater part of the land is occupied by prairies and oak openings. In 1850 the productions were 347,250 bushels of wheat, 122,290 of Indian corn, 243,601 of oats, and 266,214 lbs. of butter. There were 4 churches, and 2,707 pupils attending public schools. Organized in 1839. Three railroads centre at Madison, the capital of the state and county.

DANE, Nathan, an American jurist, born in Ipswich, Mass., in 1752, died in Beverly in 1835. He entered Harvard college in 1774, was graduated in 1778 with high reputation, studied law in Salem, Mass., and began practising in the adjoining town of Beverly in 1782, where he resided until his death. He was among the most eminent lawyers in New England, and was repeatedly placed by his fellow citizens in offices of great importance. He was in 1782, '83, '84, and '85 a member of the house of representatives of Massachusetts; in 1785, '86, and '87, a delegate to the continental congress; in 1790, '94, '96, '97, and '98, a member of the senate of Massachusetts; in 1795, a commissioner to revise the laws of that state; in 1811, to revise and publish the charters which had been granted therein; and again in 1812, to

make a new publication of the statutes. In 1794 he was appointed a judge of the court of common pleas for Essex co., Mass., and took the oaths of office, but almost immediately resigned. In 1812 he was chosen an elector of president of the United States; in 1814 he was a member of the Hartford convention; and in 1820 he was chosen a member of the convention for revising the constitution of Massachusetts; but a deafness which had been growing upon him for some years had at this time so much increased, that he declined for this reason to take his seat in the convention. He was not eloquent, either at the bar or in legislative bodies; nor did he, perhaps, possess any of the attributes of genius. But he had great good sense and a sound judgment, and was faithful to all his duties, and every one felt perfect confidence in his industry, discretion, and integrity. As a lawyer, he was among the most learned in his province, and his large and diversified experience gave him great ability and success in the conduct of cases. He was among the most laborious students that this country ever produced; and he attributed his capacity for continuous toil to his having strengthened his constitution by working on his father's farm like any laborer until he was 21 years of age. While he was a delegate from Massachusetts to the continental congress in 1786, the best method of providing for the government of the vast territory owned by the confederacy north and west of the Ohio river came into consideration. It was determined to do this by an ordinance which should establish with much detail not only the foundation of that government, but the leading principles which should prevail in the systems of law and public policy to be in force there. The drafting of this instrument was intrusted to Dane; and it was adopted by congress without a single alteration, on July 13, 1787. The clause in it which has been the subject of most frequent and emphatic remark is that which provides "that there shall be neither slavery nor involuntary servitude in the said territory." The name of the "Northwest Territory" was given to it; and it comprehended all the territory at that time belonging to the confederacy northwest of the Ohio. Not long before his death, he stated in conversation that not until this ordinance was on the eve of enactment did the thought occur to him of inserting in it this clause respecting slavery. He incorporated in this ordinance a prohibition against all laws impairing the obligation of contracts, which the convention that formed the constitution of the United States, a few months afterward, extended to all the states of the union, by making it a part of that constitution. From 1823 to 1829 he published his "Abridgment and Digest of American Law," in 9 large octavo volumes. This work will always be a storehouse to which all must resort who desire to become acquainted with the origin and history, and what may be called the fundamental principles, of the law of this country. In 1829 he imparted new vigor and life to the law school in Harvard university, in Cambridge, by giving $10,000 (adding $5,000 more in 1831) for the foundation of the Dane professorship of law, with the request that his friend Judge Story should hold the office, which he did until his death. During 50 years he devoted his Sundays (the hours of public worship, of which he was a regular attendant, alone excepted) to theological studies, generally reading the Scriptures in their original languages.

DANEGELT (Sax. *gelt*, money), an ancient tax paid by the Saxons in England, either for buying peace with the Danes, or for making preparations against the inroads of that nation. It was first paid in the year 991, when a band of Northmen attacked Ipswich, and advanced through an unguarded country as far as Maldon. Instead of meeting the enemy in the field, King Ethelred accepted the counsel of his nobles, and purchased the retreat of the invaders by a bribe of £10,000 in silver. This soon became a permanent tax under the name of Danegelt, raised by an assessment upon landed property. The last instance of its payment was under Henry II. in 1173.

DANICAN, François André, better known as Philidor, a French composer and chess-player, born at Dreux, Sept. 7, 1727, died in London, Aug. 30, 1795. His father and grandfather were musicians, and the latter, who was flutist to Louis XIII., received from that monarch the surname of Philidor, which had been borne by a celebrated hautboyist of the time, and this name was retained by his descendants. André was admitted at an early age as chorister in the chapel of Louis XV., studied composition under Campra, and at 15 years of age produced a motet for a full choir, which was performed before the court at Versailles to the great satisfaction of the king. Upon leaving the chapel he supported himself by teaching and copying music, and in 1745 commenced a tour through Germany, Holland, and England, in the course of which he exhibited his skill in the game of chess, which he had a short time before begun to cultivate. He returned to Paris in 1754, and devoted himself chiefly to his profession. Failing in an attempt to receive the appointment of *maître de la chapelle*, he wrote for the *opéra comique* with considerable success. In 1777 he revisited London, where he published his treatise on chess, his skill in which he turned to a very profitable account. He continued to compose for the comic stage, and produced airs and choruses for the *Carmen Seculare* of Horace, performed in London in 1779; but the last 10 years of his life were almost entirely devoted to his favorite game, which had become a passion with him. In Paris he played at the *café de la régence*, where the greatest players in France assembled, and in London at Parsloe's club in St. James's street. At both places he maintained a supremacy which his contemporaries rarely disputed on equal terms, and which reached its highest point when he performed what was then con-

sidered the marvellous feat of playing 3 simultaneous games blindfolded, against skilful antagonists, each of whom he defeated. A month before his death he played 2 games in the same manner, and was again successful. His death was hastened by grief, occasioned by the refusal of the French government to allow him to return to his native country. Danican's mental powers were exercised almost exclusively in chess or music. In other respects he was of less than ordinary intelligence, or, as Laborde once said of him: "He has no common sense; it is all genius." His treatise on chess has been frequently republished in foreign languages.

DANIEL (*i. e.* God is my judge), a prophet in the Chaldean and Persian period of sacred history. He was descended from one of the highest families in Judah, if not even of royal blood. Jerusalem is supposed to have been his birthplace. At the age of 12 or 16 we find him in Babylon, whither he had been carried with 3 other Hebrew youths of rank, Hananiah, Mishael, and Azariah, at the first deportation of the people of Judah in the 4th year of Jehoiakim. He and his companions were selected for the purpose of being instructed in the language and literature of the Chaldeans, with a view to their being employed in the service of the court. On this occasion the names of all 4 were changed, and Daniel was henceforth called Belteshazzar, *i. e.* prince of Belus or Bel. After the lapse of 3 years we find him interpreting a dream of the king so much to his satisfaction that he rose into high favor, and was intrusted with the governorship of the province of Babylon, and the head inspectorship of the sacerdotal caste. Considerably later in the reign of Nebuchadnezzar, we find Daniel interpreting another dream of his, to the effect that in consequence of his pride he would be deprived for a time of his reason and his throne, and after being exiled from the abodes of men, would be eventually restored to his senses and his rank. Under the immediate successor of Nebuchadnezzar, Evil-Merodach, the prophet seems to have been forgotten. No mention is made of him during this reign, or in the short reign of his successor; and in the last Chaldean reign he is mentioned in connection with the closing scene of Belshazzar's life. Belshazzar having had a remarkable vision of a handwriting on the wall, which none of the wise men of the Chaldeans could read and interpret, Daniel, at the instance of the queen mother, who remembered his former services, was called in and read the writing, and announced to the king the impending catastrophe of his empire. Under this reign, Daniel had two of his prophetic visions (ch. vii., viii.). After the conquest of Babylon by the united powers of Media and Persia, Daniel devoted himself during the short reign of Darius the Mede to the affairs of his people and their possible return from exile, the time of which, according to the prophecies of Jeremiah, was fast approaching. The elevation to which he was now raised was not beheld without malice and envy, and his enemies resolved if possible to compass his overthrow. They, therefore, under plausible pretences, secured the passage of a law that no one in the realm should be allowed for a certain time to offer any petition to any god or man except the king, on penalty of being thrown into a den of lions. Daniel, as they anticipated, was the first to disregard this law, by continuing his regular habit of worshipping God in prayer 3 times a day with his window open. The consequence was, that Daniel was cast into the den of lions, but was miraculously preserved; and this was the means of his being raised to more exalted honor (ch. vi.). He had at last the happiness to behold his people restored to their own land. His position at the court of the Medo-Persian government gave him the opportunity of rendering material aid to this end. Beyond the 3d year of Cyrus, during which he had another series of remarkable visions (ch. x., xi., xii.), nothing further is known of him.—The Book of Daniel takes its name not only from the principal person in it, but also and chiefly from him as its author. It occupies, however, but a third rank in the Hebrew canon, being inserted not among the prophets, but in the Hagiographa, for which various reasons have been assigned by the learned. Among these, the most probable is, that the book was originally classed with the prophets, but that at a later period, say in the first 3½ centuries A. D., when the disputes arose between the Christians and the Jews about the Messiah, the latter felt themselves to be so pressed by the prediction in Dan. ix. respecting the 70 weeks, that they sought to give the book a lower place than it had occupied before, and thus, by detaching it from its connection with the other prophets, to diminish the force of the argument that Jesus of Nazareth was the Christ. The genuineness and authenticity of the book of Daniel were for a long time unquestioned in the church, Porphyry, a learned adversary of the Christian faith in the 3d century, having been the first to assail its authority. His objections were answered by Eusebius, Apollinarius, Methodius, and Jerome. No further attack was made until the 17th century, when the question was raised whether the whole book was written by Daniel. But in more recent times the genuineness of the book has been questioned or denied in whole or in part by men of high repute in the German school of criticism, such as Corrodi, Gesenius, Dereser, Scholl, Lengerke, Eichhorn, DeWette, Griesenger, Bertholdt, Bleek, Ewald, Hitzig, and Kirms. It has been defended, on the other hand, by the English writers generally, and among the Germans by Staüdlin, Beckhaus, Jahn, Hävernick, Hengstenberg, and others; but more especially by Hengstenberg, whose "Authenticity of Daniel" goes over the whole ground, and embodies the ablest defence of the book that has yet appeared. For a detailed view of all the arguments employed on both sides in this controversy, the reader is referred to Mr. Barnes's introduction to his "Notes on Daniel."

DANIEL, Peter Vyvian, an American judge, born in Stafford co., Va., about 1785. His ancestors were substantial land owners, and during the revolution, in common with most of their class at that day, strenuously advocated resistance to the British government. In accordance with the prevailing practice in Virginia, he received the rudiments of his education under a private tutor, and was graduated at Princeton college in 1805, after which he studied the law at Richmond with Edmund Randolph, whose youngest daughter he afterward married. He was admitted to the bar in 1808. In 1809 he was elected a delegate to the legislature from Stafford co., and was reëlected in 1810. In 1812 he was elected a member of the privy council, and was successively reëlected councillor until the adoption of the new constitution in 1830. For a large portion of this time he was lieutenant-governor, and *ex officio* president of the council. Upon the adoption of the amended constitution in 1830, he was again elected privy councillor, the number of members composing the board being then reduced from 8 to 3. In 1835 the whigs had a majority of the legislature, and Judge Daniel with other democrats was ejected from office. He was restored at the following session, the democrats having regained their ascendency. In 1834, when Chief Justice Taney was transferred to the treasury department from the office of attorney-general, Judge Daniel was invited to the vacant position by President Jackson, but declined the appointment. In 1836 he was appointed by the president judge of the U. S. district court for the district of Virginia, to fill a vacancy occasioned by the transfer of Philip P. Barbour to the supreme bench. Upon the death of Judge Barbour in 1840, Judge Daniel was appointed as his successor by President Van Buren. He still holds the office.

DANIEL, Samuel, an English author, born in Somersetshire in 1562, died in Oct. 1619. He was the son of a music master, and was educated at Magdalen hall, Oxford, under the patronage of the Pembroke family. He devoted himself while in the university to the study of poetry and history, and left it in 1582 without taking his degree. He resided for some time with the earl of Pembroke, and became tutor to Lady Anne Clifford, subsequently countess of Pembroke. After the death of Spenser, he became "voluntary laureate" to Queen Elizabeth, but was soon superseded by Ben Jonson. During the reign of James he was appointed gentleman extraordinary and groom of the privy chamber to Queen Anne, who took great delight in his conversation and writings. His poems are numerous, comprising an epic in 6 books, on the wars of the Roses, several dramatic pieces, and many short poems. They are marked by grace of language and sweetness of thought, and have been highly esteemed by Wordsworth and other recent poets. He sought the smoothness of rhythm and simplicity of narrative characteristic of much of the Italian and Spanish poetry, and in respect of language he is among the best writers of his time. Beside his poems, he wrote in prose a "Defence of Rhyme," and a history of England from the Norman conquest to the end of the reign of Edward III., which exhibit a purity of style hardly equalled by any other work of so early a date.

DANIELL, John Frederic, an English natural philosopher, born in London, March 12, 1790, died there, March 13, 1845. He was a pupil of Brande, and afterward began business as a sugar refiner. In 1816 he began, in connection with Prof. Brande, the "Quarterly Journal of Science," of which they published the first 20 volumes. In 1820 he published a description of a new hydrometer, by which for the first time regular and accurate observations on the dryness and moisture of the air were made practicable. His great work, "Meteorological Essays," appeared in 1823. This was the first attempt to explain the principles of meteorology by the general laws regulating the temperature and constitution of gases and vapors. One of the most interesting of his theories was that which he proposed to account for the horary oscillations or periodic daily rise and fall of the barometer, by which he predicted the occurrence of a fall near the poles coincident with the rise at the equator, a conjecture afterward confirmed by actual observation. In 1824 he published an essay on "Artificial Climate," and about the same time became managing director of the continental gas company, and travelled through many of the European cities making the arrangements by which they are lighted at the present day. He was also the inventor of a process for extracting inflammable gas from resin. On the establishment of King's college in 1831 he was appointed professor of chemistry, which office he held until his death. About this time he published an account of his new pyrometer for measuring high temperatures, such as are employed in fusing metals, in furnaces, &c. Thenceforth he gave his attention principally to voltaic electricity. In 1836, in a paper communicated to the royal society, he described his valuable improvement in the voltaic battery, by which, avoiding the rapid decline of power in the ordinary batteries, he showed how a powerful and continuous current may be kept up for an unlimited period. In 1839 appeared his "Introduction to Chemical Philosophy," a treatise on the molecular forces. Beside these works there was hardly a year of his life in which valuable communications from his pen did not appear in his journal, or in the "Transactions of the Royal Society." He was the only person who ever received the 3 medals in the gift of the royal society, of which he was a zealous member, and for the last 6 years of his life foreign secretary. He expired suddenly of apoplexy, while attending a meeting of the council of the royal society.

DANIELL, Samuel, an English artist and traveller, born in 1777, died in the island of Ceylon in 1811. He spent 3 years at the cape of

Good Hope, and afterward proceeded to the interior of Africa, making sketches of the scenery and people, which he brought home with him to England in 1804, when they were published, with an account of the animals of southern Africa. He afterward went to the island of Ceylon, and during a residence of 6 years collected a large amount of similar materials, one volume of which was published, with a description of that country and its inhabitants, in 1808.

DANIELL, Thomas, an English landscape painter and engraver, born in 1749, died in 1840. In company with his nephew, William, he made an extraordinary journey through India, for the purpose of preparing sketches and illustrations of the scenery, which were afterward published. He was originally a heraldry painter, and became fellow of the royal, Asiatic, and antiquarian societies. He published several works on India.

DANIELL, William, an English painter and engraver, born in 1769, died in 1837. He set out at the age of 14, in company with his uncle Thomas, upon an artistic exploration of the peninsula of Hindostan. They commenced their journey at Cape Comorin, and sketched almost every thing beautiful or interesting in the country between that point and Serinagur, in the Himalaya mountains. They were occupied 10 years in this undertaking. Of their immense number of sketches, they selected and published a portion in a great work entitled "Oriental Scenery" (6 vols. folio, 1808). Five of these volumes were engraved by William, or under his direction; the other was engraved by Thomas, after drawings by James Wales. William also published "A Picturesque Voyage to India," "Zoography," "Animated Nature," &c., and from 1814 to 1825 was engaged in making sketches for "A Voyage round Great Britain," a work of a similar character to that which he had executed on India. Beside these, he painted many oil paintings of Indian scenery, among them a panorama of Madras, the "City of Lucknow," and the "Elephant Hunt," and was the chief contributor to the "Oriental Annual."

DANILO I. (Petrovitch Niegosh), reigning prince of Montenegro, born May 25, 1826, was educated in Vienna, succeeded, Oct. 31, 1851, his uncle, Peter Petrovitch, and was proclaimed vladika, Jan. 13, 1852. He then proceeded to St. Petersburg, to be confirmed in his dignity by the czar, and obtained the sanction of Russia for various innovations, which he carried into effect on his return to Montenegro. The most prominent of these was the separation of the civil from the ecclesiastical power that had previously been vested in the vladika. Conferring the latter upon one of his relatives, to whom he gave the title of archimandrite, he assumed the civil power under the name of Danilo I. Other changes which he had projected were interrupted by the war with Turkey, and by intestine commotions. In 1855 Danilo married the daughter of a banker of Trieste, who brought him a dowry of $50,000. About the same time, the war between Russia and Turkey and her allies was brought to a close. The prince now endeavored, but in vain, to be recognized as an independent sovereign by the treaty of Paris. In Sept. 1856, he addressed a note to the principal European powers, urging his claims to the sovereignty of Montenegro, and proposing to annex a portion of the Herzegovina and Albania, and the port of Antivari on the Adriatic. Early in 1857 he repaired to Vienna and Paris to plead his cause in person, appointing his brother regent during his absence; but a conspiracy, instigated by one of his uncles, soon compelled him to return to Montenegro, and he has since been engaged in hostilities with Turkey.

DANISH LANGUAGE and LITERATURE. See Denmark.

DANNECKER, Johann Heinrich von, a German sculptor, born at Waldenbuch, near Stuttgart, Oct. 15, 1758, died Dec. 8, 1841. His father was groom to the duke of Würtemberg, and Dannecker grew up with a very limited education. He manifested a taste for drawing at a very early age, and for want of better materials, resorted to the yard of a stone-cutter, and covered the slabs therein with his designs. In 1771 he entered, in spite of his father's opposition, the military school established by the duke at Ludwigsburg, where, on his examination, his talent for art was clearly evinced. When he was 16, he obtained a prize for his model of Milo of Crotona. He here formed a friendship with Schiller, his fellow pupil, which lasted while the poet lived, and in whose memory he sculptured a noble statue and several busts, one of them of colossal size. On leaving the school in 1780, he was appointed statuary to the court, and 3 years afterward went to Paris on foot, having only his small salary, as statuary, of about $125 a year. He remained 2 years in Paris, finding much encouragement from his master, Pajou, and then made his way on foot to Rome. Here he became acquainted with Canova, who rendered him much service. His first work in marble was chiselled in Rome, where he made statues of Ceres and Bacchus, which procured his admission into the academies of Milan and Bologna. In 1790, after having spent 5 years in Rome, he returned to his native country, and was made a professor of the fine arts in the academy of Stuttgart. In 1796 he produced several works in marble, among them a Sappho; and afterward was employed by Frederic of Würtemberg upon a monument to Count Zeppelin, representing a figure of friendship weeping over a coffin. This he finished in 1804, and in 1809 began his most celebrated work, Ariadne, which is now in Bethmann's garden, at Frankfort-on-the-Main. In 1812 he was again employed by King Frederic, on a statue of Cupid. His greatest work is his colossal statue of Christ, on which he spent 8 years. This was ordered by the empress-mother of Russia, and presented to her son Alexander I. In 1826 he executed a statue of St. John, which is also

ranked among his best productions. Among modern sculptors he occupies a medium place between Canova and Thorwaldsen.

DANNEMORA, a township of Clinton co., N. Y., 150 m. N. of Albany, formed from Beekmantown in 1854; pop. in 1855, 723. It is the seat of Clinton state prison, which in 1857 contained 274 convicts, mostly employed in the neighboring iron works and mines. In 1852, when the number of inmates was only 155, the annual expenses of the institution exceeded the prisoners' earnings by about $27,000.

DANNER, Luise Christina, countess, morganatic wife of Frederic VII. of Denmark, born in Copenhagen, April 21, 1814. Her maiden name was Rasmussen. She was only 15 when she attracted the attention of Frederic. At first she supported herself as a governess in a Norwegian family, and afterward as a milliner. Toward 1845, when Frederic, who had been absent from Copenhagen, returned to the Danish capital, he renewed his acquaintance with her. On Jan. 20, 1848, on his accession to the throne of Denmark, he conferred upon her the title of Countess Danner, and on Aug. 7, 1850, contracted a morganatic marriage with her in the chapel of the palace of Frederiksborg. She has founded several charitable institutions, and in 1852 and 1854, when she accompanied the Danish sovereign in his tour through the provinces, she was everywhere received with great cordiality by the people.

DANTAN, Jean Pierre, a French sculptor, born in Paris, Dec. 25, 1800. He is chiefly distinguished by his humorous and grotesque busts of eminent contemporaries.

DANTE (Durante, by contraction Dante) DEGLI ALIGHIERI, the illustrious Italian poet, was born at Florence in 1265, probably during the month of May.* This is the date given by Boccaccio, who is generally followed, though he makes a blunder in saying, *sedendo Urbano quarto nella cattedra di San Pietro*, for Urban died in October, 1264. Some, misled by an error in a few of the early manuscript copies of the *Divina Commedia*, would have him born 5 years earlier, in 1260. According to Arrivabene (*Secolo di Dante*, Udine edition of 1828, vol. iii. part i. p. 578), Sansovino was the first to confirm Boccaccio's statement by the authority of the poet himself, basing his argument on the first verse of the *Inferno:*

Nel mezzo del cammin di nostra vita;

the average age of man having been declared by the Psalmist to be 70 years, and the period of the poet's supposed vision being unequivocally fixed at 1300.† Leonardo Aretino and Manetti add their testimony to that of Boccaccio, and 1265 is now universally assumed as the true date. Voltaire (*Dict. Phil.*, art. "Dante"), nevertheless, places the poet's birth in 1260, and jauntily forgives Bayle (who, he says, *écrivait à Rotterdam* currente calamo *pour son libraire*) for having been right, declaring that he esteems him neither more nor less for having made a mistake of 5 years. Oddly enough, Voltaire adopts this alleged blunder of 5 years on the next page, in saying that Dante died at the age of 56, though he still more oddly omits the undisputed date of his death (1321), which would have shown Bayle to be right. The poet's descent is said to have been derived from a younger son of the great Roman family of the Frangipani, classed by the popular rhyme with the Orsini and Colonna:

Colonna, Orsini, e Frangipani,
Prendono oggi e pagano domani.

That his ancestors had been long established in Florence is an inference from some expressions of the poet, and from their dwelling having been situated in the more ancient part of the city. The most important fact of the poet's genealogy is, that he was of mixed race, the Alighieri being of Teutonic origin. Dante was born (as he himself tells us, *Parad.* xxii.) when the sun was in the constellation Gemini, and it is supposed from a passage in the *Inferno* (Canto xv.) that his horoscope was drawn and a great destiny predicted for him by his teacher, Brunetto Latini. The *Ottimo Comento* tells us that the Twins are the house of Mercury, who induces in men the faculty of writing, science, and of acquiring knowledge. This is worth mentioning as characteristic of the age and of Dante himself, with whom the influence of the stars took the place of the old notion of destiny (*Purg.* xvi.). It is supposed from a passage in Boccaccio's life of Dante, that Alighiero the father was still living when the poet was 9 years old. If so, he must have died soon after, for Leonardo Aretino, who wrote with original documents before him, tells us that Dante lost his father while yet a child. This circumstance may have been not without influence in muscularizing his nature to that character of self-reliance which shows itself so constantly and sharply during his after life. His tutor was Brunetto Latini, a very superior man (for that age), says Aretino parenthetically. Like Alexander Gill, he is now remembered only as the schoolmaster of a great poet, and that he did his duty well may be inferred from Dante's speaking of him gratefully as one who by times "taught him how man eternizes himself." This, and what Villani says of his refining the Tuscan idiom (for so we understand his *farli scorti in bene parlare**), are to be noted as of probable influence on the career of his pupil. Of the order of Dante's studies nothing can be certainly

* The *Nouvelle biographie générale* gives May 8 as his birthday. This is a mere assumption, for Boccaccio only says generally May. The indication which Dante himself gives that he was born when the sun was in Gemini would give a range from about the middle of May to about the middle of June, so that the 8th is certainly too early.

† Arrivabene, however, is wrong. Boccaccio makes precisely the same reckoning in the first note of his commentary (Bocc. *Comento*, &c., Firenze, 1844, vol. i. pp. 32, 33).

* Though he himself preferred French, and wrote his *Trésor* in that language for two reasons, *l'una perchè noi siamo in Francia, e l'altra perchè la parlatura francesca è più dilettevole e più comuna che tutti li altri linguaggi.*" (*Proemio, sul fine.*)

affirmed. His biographers send him to Bologna, Padua, Paris, Naples, and even Oxford. All are doubtful, Paris and Oxford most of all, and the dates utterly undeterminable. Bologna and Padua we should be inclined to place before his exile, Paris and Oxford, if at all, after it. If no argument in favor of Paris is to be drawn from his *Pape Satan* (*Inf.* canto vii.) and the corresponding *paix, paix, Sathan*, in the autobiography of Cellini, nor from the very definite allusion to Doctor Siger (*Par.* canto x.), we may yet infer from some passages in the *Commedia* that his wanderings had extended even further (see especially *Inf.* ix. 112 *et seq.*; xii. 120; xv. 4 *et seq.*; xxxii. 25–30); for it would not be hard to show that his comparisons and illustrations from outward things are almost invariably drawn from actual eyesight. As to the nature of his studies, there can be no doubt that he went through the *trivium* (grammar, dialectics, rhetoric) and the *quadrivium* (arithmetic, music, geometry, and astronomy) of the then ordinary university course. To these he afterward added painting (or at least drawing—*designavo un angelo sopra certe tavolette*—*Vit. Nuov.* p. 61, ed. Pesaro, 1829), theology, and medicine. He is said to have been the pupil of Cimabue, and was certainly the friend of Giotto, the designs for some of whose frescoes at Assisi and elsewhere have been wrongly attributed to him. To prove his love of music, the episode of Casella were enough, even without Boccaccio's testimony. The range of Dante's study and acquirement would be encyclopædic in any age, but at that time it was literally possible to master the *omne scibile*, and he seems to have accomplished it. How lofty his theory of science was, is plain from this passage in the *Convito:* "He is not to be called a true lover of wisdom (*filosofo*) who loves it for the sake of gain, as do lawyers, physicians, and almost all priests (*li religiosi*), who study, not in order to know, but to acquire riches or advancement, and who would not persevere in study should you give them what they desire to gain by it. . . . . And it may be said that (as true friendship between men consists in each wholly loving the other) the true philosopher loves every part of wisdom, and wisdom every part of the philosopher, inasmuch as she draws all to herself, and allows no one of his thoughts to wander to other things." (*Tratt.* iii. cap. 11.) The *Convito* gives us a glance into Dante's library. We find Aristotle (whom he calls the philosopher, the master) cited 76 times; Cicero 18; Albertus Magnus 7; Boëthius 6; Plato (at second hand) 4; Aquinas, Avicenna, Ptolemy, the Digest, Lucan, and Ovid, 3 each; Virgil, Juvenal, Statius, Seneca, and Horace, twice each; and Algazzali, Alfrogan, Augustine, Livy, Orosius, and Homer (at second hand), once. Of Greek he seems to have understood little; of Hebrew and Arabic, a few words. But it was not only in the closet and from books that Dante received his education. He acquired, perhaps, the better part of it in the streets of Florence, and later, in those homeless wanderings which led him (as he says) wherever the Italian tongue was spoken. His were the only open eyes of that century, and, as nothing escaped them, so there is nothing that was not photographed upon his sensitive brain, to be afterward fixed for ever in the *Commedia*. What Florence was during his youth and manhood, with its Guelphs and Ghibellines, its nobles and trades, its Bianchi and Neri, its kaleidoscopic revolutions, "all parties loving liberty and doing their best to destroy her," as Voltaire says, it would be beyond our province to tell even if we could. Foreshortened as events are when we look back on them across so many ages, only the upheavals of party conflict catching the eye, while the spaces of peace between sink out of the view of history, a whole century seems like a mere wild chaos. Yet during a couple of such centuries the cathedrals of Florence, Pisa, and Sienna got built; Cimabue, Giotto, Arnolfo, the Pisani, Brunelleschi, and Ghiberti gave the impulse to modern art, or brought it in some of its branches to its culminating point; modern literature took its rise; commerce became a science, and the middle class came into being. It was a time of fierce passions and sudden tragedies, of picturesque transitions and contrasts. It found Dante, shaped him by every experience that life is capable of, rank, ease, love, study, affairs, statecraft, hope, exile, hunger, dependence, despair; until he became endowed with a sense of the nothingness of this world's goods possible only to the rich, and a knowledge of man possible only to the poor. The few well ascertained facts of Dante's life may be briefly stated. In 1274 occurred what we may call his spiritual birth, the awakening in him of the imaginative faculty, and of that profounder and more intense consciousness which springs from the recognition of beauty through the antithesis of sex. It was in that year that he first saw Beatrice Portinari. In 1289 he was present at the battle of Campaldino, fighting on the side of the Guelphs, who there utterly routed the Ghibellines, and where, he says, "I was present, not a boy in arms, and where I felt much fear, but in the end the greatest pleasure from the various changes of the fight." (Letter of Dante, now lost, cited by Aretino.) In the same year he assisted at the siege and capture of Caprona. (*Inf.* xxi. 94.) In 1290 died Beatrice, married to Simone dei Bardi, precisely when is uncertain, but before 1287, as appears by a mention of her in her father's will, bearing date Jan. 15 of that year. Dante's own marriage is assigned to various years, ranging from 1291 to 1294; but the earlier date seems the more probable, as he was the father of 7 children (the youngest a daughter, named Beatrice) in 1301. His wife was Gemma dei Donati, and through her Dante, whose family, though noble, was of the lesser nobility, became nearly connected with Corso Donati, the head of a powerful clan of the *grandi* or greater nobles. In 1293 occurred

what is called the revolution of Gian Della Bella, in which the priors of the trades took the power into their own hands and made nobility a disqualification for office. A noble was defined to be any one who counted a knight among his ancestors, and thus the descendant of Cacciaguida was excluded. Della Bella was exiled in 1295, but the nobles did not regain their power. On the contrary, the citizens, having all their own way, proceeded to quarrel among themselves, and subdivided into the *popolani grossi* and *popolani minuti*, or greater and lesser trades, a distinction of gentility somewhat like that between wholesale and retail tradesmen. The *grandi* continuing turbulent, many of the lesser nobility, among them Dante, drew over to the side of the citizens, and between 1297 and 1300 there is found inscribed in the book of the physicians and apothecaries, *Dante d'Aldighiero, degli Aldighieri, poeta Fiorentino.* (Balbo, *Vita di Dante*, Firenze, 1853, p. 117.) Prof. de Vericour ("Life and Times of Dante," London, 1858, p. 80) thinks it necessary to apologize for this lapse on the part of the poet, and gravely bids us take courage, nor think that Dante was ever an apothecary. In 1300 we find him elected one of the priors of the city. In order to a perfect misunderstanding of every thing connected with the Florentine politics of this period, one has only to study the various histories. The result is a spectrum on the mind's eye, which looks definite and brilliant, but really hinders all accurate vision, as if from too steady inspection of a Catharine wheel in full whirl. A few words, however, are necessary, if only to make the confusion palpable. The rival German families of Welfs and Weiblingens had given their names, softened into Guelfi and Ghibellini—from which Gabriel Harvey (notes to Spenser's "Shepherd's Calendar") ingeniously, but mistakenly, derives elves and goblins—to two parties in northern Italy, representing respectively the adherents of the pope and of the emperor, but serving very well as rallying points in all manner of intercalary and subsidiary quarrels. The nobles, especially the greater ones, perhaps from instinct, perhaps in part from hereditary tradition, as being more or less Teutonic by descent, were commonly Ghibellines or imperialists; the bourgeoisie were very commonly Guelphs or supporters of the pope, partly from natural antipathy to the nobles, and partly, perhaps, because they believed themselves to be espousing the more purely Italian side. Sometimes, however, the party relation of nobles and burghers to each other was reversed, but the names Guelph and Ghibelline always substantially represented the same things. The family of Dante had been Guelphic, and we have seen him already as a young man serving two campaigns against the other party. But no immediate question as between pope and emperor seems then to have been pending; and while there is no evidence that he was ever a mere partisan, the reverse would be the inference from his habits and character.

Just before his assumption of the priorate, however, a new complication had arisen. A family feud beginning at the neighboring city of Pistoja, between the Cancellieri Neri and Cancellieri Bianchi (see the story at length in Balbo, *Vita di Dante*, cap. x.), had extended to Florence, where the Guelphs took the part of the Neri and the Ghibellines of the Bianchi.* The city was instantly in a ferment of street brawls, as actors in one of which some of the Medici are incidentally named, the first appearance of that family in history. Both parties appealed at different times to the pope, who sent two ambassadors, first a bishop and then a cardinal. Both pacificators soon flung out again in a rage, after adding the new element of excommunication to the causes of confusion. It was in the midst of these things that Dante became one of the 6 priors (June, 1300), an office which the Florentines had made bimestrial in its tenure, in order apparently to secure at least 6 constitutional chances of revolution in the year. He advised that the leaders of both parties should be banished to the frontiers, which was forthwith done, the ostracism including his relative Corso Donati among the Neri, and his most intimate friend the poet Guido Cavalcanti among the Bianchi. They were all permitted to return before long (but after Dante's term of office was over), and came accordingly, bringing at least the scriptural allowance of "seven other" motives of mischief with them. Affairs getting worse (1301), the Neri, with the connivance of the pope (Boniface VIII.), entered into an arrangement with Charles of Valois, who was preparing an expedition to Italy. Dante was meanwhile sent on an embassy to Rome (Sept. 1301, according to Arrivabene, *Secolo di Dante*, p. 654, but probably earlier) by the Bianchi, who still retained all the offices at Florence. It is the tradition that he said in setting forth: "If I go, who remains? and if I stay, who goes?" Whether true or not, the story implies what was certainly true, that the council and influence of Dante were of great weight with the more moderate of both parties. On Oct. 31, 1301, Charles took possession of Florence in the interest of the Neri. Dante being still at Rome (Jan. 27, 1302), sentence of exile was pronounced against him and others, with a heavy fine to be paid within two months; if not paid, the entire confiscation of goods, and, whether paid or no, exile; the charge against him being pecuniary malversation in office. The fine not paid (as it could not be without admitting the justice of the charges, which Dante scorned even to deny), in less than two months (March 10, 1302) a second sentence was registered by which he with others was condemned to be burned alive if taken within the boundaries of the republic.† From this

* Thus Foscolo. Perhaps it would be more accurate to say that at first the blacks were the extreme Guelphs, and the whites those moderate Guelphs inclined to make terms with the Ghibellines. The matter is obscure, and Balbo contradicts himself about it.

† That Dante was not of the *grandi* or great nobles (what we call grandees), as some of his biographers have

time the life of Dante becomes semi-mythical, and for nearly every date we are reduced to the "as they say" of Herodotus. He became now necessarily identified with his fellow exiles (fragments of all parties united by common wrongs in a practical, if not theoretic, Ghibellinism), and shared in their attempts to reinstate themselves by force of arms. He was one of their council of 12, but withdrew from it on account of the unwisdom of their measures. Whether he was present at their futile assault on Florence (July 22, 1304) is doubtful, but probably he was not. From the *Ottimo Comento*, written at least in part* by a contemporary as early as 1333, we learn that Dante soon separated himself from his companions in misfortune with mutual discontents and recriminations. (*Ott. Com. Parad.* xvii.) During the 19 years of Dante's exile, it would be hard to say where he was not. In certain districts of northern Italy there is scarce a village that has not its tradition of him, its *sedia*, *rocca*, *spelonca*, or *torre di Dante;* and what between the patriotic complaisance of some biographers overwilling to gratify as many provincial vanities as possible, and the pettishness of others anxious only to snub them, the confusion becomes hopeless.† After his banishment we find some definite trace of him first at Arezzo with Uguccione della Faggiuola; then at Sienna; then at Verona with the Scaligeri. He himself says: "Through almost all parts where this language [Italian] is spoken, a wanderer, well nigh a beggar, I have gone, showing against my will the wound of fortune. Truly I have been a vessel without sail or rudder, driven to diverse ports, estuaries, and shores by that hot blast, the breath of grievous poverty; and I have shown myself to the eyes of many who perhaps, through some fame of me, had imagined me in quite other guise, in whose view not only was my person debased, but every work of mine, whether done or yet to do, became of less account." (*Convito*, tratt. i. cap. 3.) By the election of the emperor Henry VII. (of Luxemburg, Nov. 1308), and the news of his proposed expedition into Italy, the hopes of Dante were raised to the highest pitch. Henry entered Italy, Oct. 1310, and received the iron crown of Lombardy at Milan, on the day of Epiphany, 1311. His movements being slow, and his policy undecided, Dante addressed him that famous letter, urging him to crush first the "Hydra and Myrrha" Florence, as the root of all the evils of Italy (April 16, 1311). To this year we must probably assign the new decree by which the seignory of Florence recalled a portion of the exiles, excepting Dante, however, among others, by name.* The undertaking of Henry, after an ill-directed dawdling of two years, at last ended in his death at Buonconvento (Aug. 24, 1313; Carlyle says wrongly Sept.), poisoned, it was said, in the sacramental bread, by a Dominican friar, bribed thereto by Florence. (See Carlyle's "Frederic," Harper's ed. vol. i. p. 112.) The story is doubtful, the more as Dante nowhere alludes to it, as he certainly would have done had he heard of it. According to Balbo, Dante spent the time from Aug. 1313, to Nov. 1314, in Pisa and Lucca, and then took refuge at Verona, with Can Grande della Scala (whom Voltaire calls, drolly enough, *le grande-can de Vérone*, as if he had been a Tartar), where he remained till 1318. Foscolo with equal positiveness sends him, immediately after the death of Henry, to Guido da Polenta† at Ravenna, and makes him join Can Grande only after the latter became captain of the Ghibelline league in Dec. 1318. In 1316 the government of Florence set forth a new decree allowing the exiles to return on conditions of fine and penance. Dante rejected the offer (by accepting which his guilt would have been admitted), in a letter still hot, after these 5 centuries, with indignant scorn. "Is this then the glorious return of Dante Alighieri to his country after nearly 3 lustres of suffering exile? Did an innocence patent to all merit this? This, the perpetual sweat and toil of study? Far from a man the housemate of philosophy be so rash and earthen-hearted a humility as to allow himself to be offered up bound like a schoolboy or a criminal! Far from a man the preacher of justice to pay those who have done him wrong as for a favor! This is not the way of returning to my country; but if another can be found that shall not derogate from the fame and honor of Dante, that I will enter on with no lagging steps. For if by none such Florence may be entered, by me then never! Can I not everywhere behold the mirrors of the sun and stars? Speculate on sweetest truths under any sky without first giving myself up inglorious, nay ignominious, to the populace and city of Florence? Nor shall I want for bread." Dionisi puts the date of this letter in 1315.‡ He

tried to make out, is plain from this sentence, where his name appears low on the list and with no ornamental prefix, after half a dozen *domini*. Bayle, however, is equally wrong in supposing his family to have been obscure.

* See Witte, *Quando e da chi sia composto l'Ottimo Comento*, &c. (Leipsic, 1847).

† The loose way in which many Italian scholars write history is as amazing as it is perplexing. For example: Count Balbo's "Life of Dante" was published originally at Turin, in 1839. In a note (lib. i. cap. 10) he expresses a doubt whether the date of Dante's banishment should not be 1303, and inclines to think it should be. Meanwhile, it seems never to have occurred to him to employ some one to look at the original decree, still existing in the archives. Stranger still, Le Monnier, reprinting the work at Florence, in 1853, within a stone's throw of the document itself, and with full permission from Balbo to make corrections, leaves the matter just where it was.

* Macchiavelli is the authority for this, and is carelessly cited in the preface to the Udine edition of the *Codex Bartolinianus* as placing it in 1312. Macchiavelli does no such thing, but expressly implies an earlier date, perhaps 1310. (See Macch. Op. ed. Baretti, London, 1772, vol. i. p. 60.)

† A mistake, for Guido did not become lord of Ravenna till several years later. But Boccaccio also assigns 1313 as the date of Dante's withdrawal to that city, and his first protector may have been one of the other Polentani to whom Guido (surnamed Novello, or the younger, his grandfather having borne the same name) succeeded.

‡ Under this date (1315) a 4th *condemnatio* against Dante is mentioned, *facta in anno* 1315 *de mense Octobris per D. Rainerium D. Zacharie de Urbeveteri, olim et tunc vicarium regium civitatis Florentiæ*, &c. It is found recited in the decree under which in 1342 Jacopo di Dante redeemed a portion of his father's property, to wit: *Una possessione cum vineu et cum domibus super ea, combustis et*

is certainly wrong, for the decree is dated Dec. 11, 1316. Foscolo places it in 1316, Troya early in 1317, and both may be right, as the year began March 25. Whatever the date of Dante's visit to Voltaire's great Khan* of Verona, or the length of his stay with him, may have been, it is certain that he was in Ravenna in 1320, and that on his return thither from an embassy to Venice (concerning which a curious letter, forged probably by Doni, is extant), he died on Sept. 14, 1321 (13th according to others). He was buried at Ravenna under a monument built by his friend, Guido Novello.† Dante is said to have dictated the following inscription for it on his deathbed :

JVRA MONARCHIÆ SVPEROS PHLEGETHONTA LACVSQVE
LVSTRANDO CECINI VOLVERVNT FATA QVOVSQVE
SED QVIA PARS CESSIT MELIORIBVS HOSPITA CASTRIS
AVCTOREMQVE SVVM PETIIT FELICIOR ASTRIS
HIC CLAVDOR DANTES PATRIIS EXTORRIS AB ORIS
QVEM GENVIT PARVI FLORENTIA MATER AMORIS.

Of which this rude paraphrase may serve as a translation :

The rights of Monarchy, the Heavens, the Stream of Fire, the Pit,
In vision seen, I sang as far as to the Fates seemed fit;
But since my soul, an alien here, hath flown to nobler wars,
And, happier now, hath gone to seek its Maker 'mid the stars,
Here am I Dante shut, exiled from the ancestral shore,
Whom Florence, the of all least-loving mother, bore.‡

If these be not the words of Dante, what is internal evidence worth? The indomitably self-reliant man, loyal first of all to his most unpopular convictions (his very host, Guido, being a Guelph), puts his Ghibellinism (*jura monarchiæ*) in the front. The man whose whole life, like that of selected souls always, had been a warfare, calls Heaven another camp—a better one, thank God! The wanderer of so many years speaks of his soul as a guest—glad to be gone, doubtless. The exile, whose sharpest reproaches of Florence are always those of an outraged lover, finds it bitter that even his unconscious bones should lie in alien soil.—*Personal Characteristics ; Anecdotes.* Giovanni Villani, the earliest authority, and a contemporary, thus sketches him : "This man was a great scholar in almost every science, though a layman ; was a most excellent poet, philosopher, and rhetorician; perfect, as well in composing and versifying as in haranguing; a most noble speaker. . . . . This Dante, on account of his learning, was a little haughty, and shy, and disdainful, and like a philosopher almost ungracious, knew not well how to deal with unlettered folk." Benvenuto da Imola tells us that he was very abstracted, as we may well believe of a man who carried the *Commedia* in his brain. Boccaccio paints him in this wise : "Our poet was of middle height; his face was long, his nose aquiline, his jaw large, and the lower lip protruding somewhat beyond the upper; a little stooping in the shoulders; his eyes rather large than small; dark of complexion; his hair and beard thick, crisp, and black; and his countenance always sad and thoughtful. His garments were always dignified, the style such as suited ripeness of years ; his gait was grave and gentlemanlike ; and his bearing, whether public or private, wonderfully composed and polished. In meat and drink he was most temperate, nor was ever any more zealous in study or whatever other pursuit. Seldom spake he, save when spoken to, though a most eloquent person. In his youth he delighted especially in music and singing, and was intimate with almost all the singers and musicians of his day. He was much inclined to solitude, and familiar with few, and most assiduous in study as far as he could find time for it. Dante was also of marvellous capacity and the most tenacious memory." Various anecdotes of him are related by Boccaccio, Sacchetti, and others, none of them verisimilar, and some of them at least 15 centuries old when revamped. Most of them are neither *veri* nor *ben trovati*. One clear glimpse we get of him from the *Ottimo Comento*, the author of which says (*Inf.* x. 85): "I, the writer, heard Dante say that never a rhyme had led him to say other than he would, but that many a time and oft (*molte e spesse volte*) he had made words say for him what they were not wont to express for other poets." That is the only sincere glimpse we get of the living, breathing, word-compelling Dante. —*The Posthumous Dante.* Looked at outwardly, the life of Dante seems to have been an utter and disastrous failure. What its inward satisfactions must have been, we, with the *Paradiso* open before us, can form some faint conception. To him, longing with an intensity

non combustis, posita in populo S. Miniatis de Pagnola. In the *domibus combustis* we see the blackened traces of Dante's kinsman by marriage, Corso Donati, who plundered and burnt the houses of the exiled Bianchi, during the occupation of the city by Charles of Valois. (See De Romanis, notes on Tiraboschi's Life of Dante, in the Florence ed. of 1830, vol. v. p. 119.)

* Voltaire's blunder has been made part of a serious theory by Mons. E. Aroux, who gravely assures us that, during the middle ages, Tartar was only a cryptonyme by which heretics knew each other, and adds: *Il n'y a donc pas trop à s'étonner des noms bizarres de Mastino et de Cane donnés à ces Della Scala.* (*Dante, hérétique, révolutionnaire, et socialiste*, Paris, 1854, pp. 118–120.)

† If no monument at all was built by Guido, as is asserted by Balbo (*Vita*, l. ii. cap. xvii.), whom De Vericour copies without question, we are at a loss to account for the preservation of the original epitaph replaced by Cardinal Bembo when he built the new tomb, in 1483. Bembo's own inscription implies an already existing monument, and, if in disparaging terms, yet epitaphial Latin verses are not to be taken too literally, considering the exigencies of that branch of literary activity. The doggerel Latin has been thought by some unworthy of Dante, as Shakespeare's doggerel English epitaph has been thought unworthy of him. In both cases the rudeness of the verses seems to us a proof of authenticity. An enlightened posterity with unlimited superlatives at command, and in an age when stone-cutting was cheap, would have aimed at something more befitting the occasion. It is certain, at least in Dante's case, that Cardinal Bembo would never have inserted in the very first words an allusion to the *De Monarchiâ*, a book long before condemned as heretical.

‡ We have translated *lacusque* by "the Pit," as being the nearest English correlative. Dante probably meant by it the several circles of his Hell, narrowing, one beneath the other, to the centre. As a curious specimen of English we subjoin Prof. De Vericour's translation: "I have sang the rights of monarchy; I have sang, in exploring them, the abode of God, the Phlegethon and the impure lakes, as long as destinies have permitted. But as the part of myself, which was only passing, returns to better fields, and happier, returned to his Maker, I, Dante, exiled from the regions of the fatherland, I am laid here, I, to whom Florence gave birth, a mother who experienced but a feeble love." (The "Life and Times of Dante," London, 1858, p. 208.)

which only the word *Dantesque* will express to realize an ideal upon earth, and continually baffled and misunderstood, the far greater part of his mature life must have been labor and sorrow. We can see how essential all that sad experience was to him, can understand why all the fairy stories hide the luck in the ugly black casket; but to him, then and there, how seemed it?

> Thou shalt relinquish every thing of thee,
> Beloved most dearly; this that arrow is
> Shot from the bow of exile first of all;
> And thou shalt prove how salt a savor hath
> The bread of others, and how hard a path
> To climb and to descend the stranger's stairs!
> (*Par.* xvii.)

Come sa di sale! Who never wet his bread with tears, says Goethe, knows ye not, ye heavenly powers! Our 19th century made an idol of the noble lord who broke his heart in verse once every 6 months, but the 14th was lucky enough to produce and not to make an idol of that rarest earthly phenomenon, a man of genius who could hold heartbreak at bay for 20 years, and would not let himself die till he had done his task. At the end of the *Vita Nuova*, his first work, Dante wrote down that remarkable aspiration that God would take him to himself after he had written of Beatrice such things as were never yet written of woman. It was literally fulfilled when the *Commedia* was finished 25 years later.—Scarce was Dante at rest in his grave when Italy felt instinctively that this was her great man. Boccaccio tells us that in 1329* Cardinal Poggetto (du Poiet) caused Dante's treatise *De Monarchiâ* to be publicly burned at Bologna, and proposed further to dig up and burn the bones of the poet at Ravenna, as having been a heretic; but so much opposition was roused that he thought better of it. Yet this was during the pontificate of the Frenchman, John XXII., the reproof of whose simony Dante puts in the mouth of St. Peter, who declares his seat vacant (*Parad.* xxvii.), whose damnation the poet himself seems to prophesy (*Inf.* xi.), and against whose election he had endeavored to persuade the cardinals, in a vehement letter. In 1350 the republic of Florence voted the sum of 10 golden florins to be paid by the hands of Messer Giovanni Boccaccio to Dante's daughter Beatrice, a nun in the convent of Santa Chiara at Ravenna. In 1396 Florence voted a monument, and begged in vain for the metaphorical ashes of the man of whom she had threatened to make literal cinders if she could catch him alive. In 1429† she begged again, but Ravenna, a dead city, was tenacious of the dead poet. In 1519 Michel Angelo would have built the monument, but Leo X. refused to allow the sacred dust to be removed. Finally, in 1829, 508 years after the death of Dante, Florence got a cenotaph fairly built in Santa Croce (by Ricci), ugly beyond even the usual lot of such, with 3 colossal figures on it, Dante in the middle, with Italy on one side and Poesy on the other. The tomb at Ravenna, built originally in 1483, by Cardinal Bembo, was restored by Cardinal Corsi in 1692, and finally rebuilt in its present form by Cardinal Gonzaga, in 1780, all three of whom commemorated themselves in Latin inscriptions. It is a little shrine covered with a dome, not unlike the tomb of a Mohammedan saint, and is now the chief magnet which draws foreigners and their gold to Ravenna. The *valet de place* says that Dante is not buried under it, but beneath the pavement of the street in front of it, where also, he says, he saw my lord Byron kneel and weep. Like every thing in Ravenna, it is dirty and neglected. In 1373 (Aug. 9) Florence instituted a chair of the *Divina Commedia*, and Boccaccio was named first professor. He accordingly began his lectures on Sunday, Oct. 3, following, but his comment was broken off abruptly at the 17th verse of the 17th canto of the *Inferno* by the illness which ended in his death, Dec. 21, 1375. Among his successors were Filippo Villani and Filelfo. Bologna was the first to follow the example of Florence, Benvenuto da Imola having begun his lectures, according to Tiraboschi, as early as 1375. Chairs were established also at Pisa, Venice, Piacenza, and Milan before the close of the century. The lectures were delivered in the churches and on feast days, which shows their popular character. Balbo reckons (but this is guess work) that the MS. copies of the *Divina Commedia* made during the 14th century, and now existing in the libraries of Europe, are more numerous than those of all other works, ancient and modern, made during the same period. Between the invention of printing and the year 1500 more than 20 editions were published in Italy, the earliest in 1472. During the 16th century there were 40 editions; during the 17th, a period, for Italy, of sceptical dilettantism, only 3; during the 18th, 34; and already, during the first half of the 19th, at least 80. The first translation was into Spanish, in 1428.* M. St. René Taillandier says that the *Commedia* was condemned by the inquisition in Spain, but this seems too general a statement, for, according to Foscolo ("Dante," vol. iv. p. 116), it was the commentary of Landino and Vellutello, and a few verses in the *Inferno* and *Paradiso*, which were condemned. The first French translation was that of Grangier, 1596, but the study of Dante struck no root there till the present century. Rivarol, who translated the *Inferno* in 1783, was the first Frenchman who divined the wonderful force and vitality of the *Commedia*.† The expressions of Voltaire represent very well the average opinion of cultivated persons in respect of Dante in the middle of the 18th century. He says: "The Italians call him divine; but it is a hidden divinity; few people understand his oracles. He has commentators, which, perhaps, is another reason for his not being understood. His reputation will go on

* He says after the return of Louis of Bavaria to Germany, which took place in that year. The *De Monarchiâ* was afterward condemned by the council of Trent.

† See the letter in Gaye, *Carteggio inedito d'artisti*, vol. i. p. 123.

* Saint René Taillandier, in *Revue de deux mondes*, Dec. 1, 1856.

† Ste. Beuve, *Causeries du Lundi*, tome xi. p. 169.

increasing, because scarce anybody reads him." (*Dict. Phil.*, art. "Dante.") To Father Bettinelli he writes: "I estimate highly the courage with which you have dared to say that Dante was a madman and his work a monster." But he adds, what shows that Dante had his admirers even in that flippant century: "There are found among us, and in the 18th century, people who strive to admire imaginations so stupidly extravagant and barbarous." (*Corresp. gén.*, *Œuvres*, t. lvii. pp. 80–81.) Elsewhere he says that the *Commedia* was "an odd poem, but gleaming with natural beauties, a work in which the author rose in parts above the bad taste of his age and his subject, and full of passages written as purely as if they had been of the time of Ariosto and Tasso." (*Essai sur les mœurs*, *Œuvres*, t. xvii. pp. 371–'2.) It is curious to see this antipathetic fascination which Dante exercised over a nature so opposite to his own. At the beginning of this century Châteaubriand speaks of Dante with vague commendation, evidently from a very superficial acquaintance, and that only with the *Inferno*, probably from Rivarol's version. (*Génie du Christianisme*, t. iv. cap. 14.) Since then there have been 4 or 5 French versions in prose or verse, including one by Lamennais. But the austerity of Dante will not condescend to the conventional elegance which makes the charm of French, and the most virile of poets cannot be adequately rendered in the most feminine of languages. Yet in the works of Fauriel, Ozanam, Ampère, and Villemain, France has given a greater impulse to the study of Dante than any other country except Germany. Into Germany the *Commedia* penetrated later. How utterly Dante was unknown there in the 16th century is plain from a passage in the "Vanity of the Arts and Sciences" of Cornelius Agrippa, where he is spoken of among the authors of lascivious stories: "There have been many of these historical pandars, of which some of obscure fame, as Æneas Sylvius, Dantes, and Petrarch, Boccace, Pontanus," &c. (Ed. Lond. 1684, p. 199.) The first German translation was that of Kannegiesser (1809). Versions by Streckfuss, Kopisch, and Prince John (now king) of Saxony followed. Goethe seems never to have given that attention to Dante which his ever-alert intelligence might have been expected to bestow on so imposing a moral and æsthetic phenomenon. Unless the conclusion of the second part of "Faust" be an inspiration of the *Paradiso*, we remember no adequate word from him on this theme. His remarks on one of the German translations are brief, dry, and without that breadth which comes only of thorough knowledge and sympathy. But German scholarship and constructive criticism, through Witte, Kopisch, Wegele, Ruth, and others, have been of preëminent service in deepening the understanding and facilitating the study of the poet. In England, the first recognition of Dante is by Chaucer in the "Hugelin of Pisa" of the "Monkes Tale,"* and an imitation of the opening verses of the 3d canto of the *Inferno* ("Assembly of Foules"). In 1417 Giovanni da Serravalle, bishop of Fermo, completed a Latin prose translation of the *Commedia*, a copy of which, as he made it at the request of two English bishops whom he met at the council of Constance, was doubtless sent to England. Later we find Dante now and then mentioned, but evidently from hearsay only,* till the time of Milton, who shows that he had read his works closely. Thenceforward for more than a century Dante became a mere name, used without meaning by literary sciolists. Lord Chesterfield echoes Voltaire, and Dr. Drake in his "Literary Hours" (2d ed., 1800) could speak of Darwin's "Botanic Garden" as showing the "wild and terrible sublimity of Dante"! The first complete English translation was by Boyd, of the *Inferno* 1785, of the whole poem 1802. There have been 6 other complete translations, beginning with Cary's in 1814, 4 since 1850, beside several of the *Inferno* singly. It is only within the last 20 years, however, that the study of Dante, in any true sense, became at all general. Even Coleridge seems to have been familiar only with the *Inferno*. In America, Prof. Ticknor was the first to devote a special course of illustrative lectures to Dante; he was followed by Longfellow, whose lectures, illustrated by admirable translations, are remembered with grateful pleasure by many who were thus led to learn the full significance of the great Christian poet. A translation of 10 cantos of the *Inferno* into quatrains by T. W. Parsons (1843) ranks with the best for spirit, faithfulness, and elegance. The entire *Inferno* is looked for soon from the same competent hand. In Denmark and Russia translations of the *Inferno* have been published, beside separate volumes of comment and illustration. We have thus sketched the steady growth of Dante's fame and influence to a universality unparalleled except in the case of Shakespeare, perhaps more remarkable if we consider the abstruse and mystical nature of his poetry. It is to be noted as characteristic that the veneration of Dantophilists for their master is that of disciples for their saint. Perhaps no other man could have called forth such an expression as that of Ruskin, that "the central man of all the world, as representing in perfect balance the imagination, moral and intellectual faculties, all at their highest, is Dante."—*The Works of Dante.* (*a.*) The *Vita Nuova*. The first remark to be made upon the writings of Dante is that they are all (with the possible exception of the treatise *De Vulgari Eloquio*) autobiographic, and that all of them, including that, are parts of a mutually

* It is worth notice, as a proof of Chaucer's critical judgment, that he calls Dante "the great poet of Itaille," while in the "Clerke's Tale" he speaks of Petrarch as a "worthy clerk," as "the laureat poete" (alluding to the somewhat sentimental ceremony at Rome), and says that his

> "Rhetorike sweete
> Enlumined all Itaille of poetry."

* It is possible that Sackville may have read the *Inferno*, and it is certain that Sir John Harrington had. See the preface to his translation of the *Orlando Furioso*.

related system, of which the central point is the individuality and experience of the poet. In the *Vita Nuova* he recounts the story of his love for Beatrice Portinari, showing how his grief for her loss turned his thoughts first inward upon his own consciousness, and, failing all help there, gradually upward through philosophy to religion, and so from a world of shadows to one of eternal substances. It traces with exquisite unconsciousness the gradual but certain steps by which memory and imagination transubstantiated the woman of flesh and blood into a holy ideal, combining in one radiant symbol of sorrow and hope the faith which is the instinctive refuge of unavailing regret, the grace of God which higher natures learn to find in the trial which passeth all understanding, and that perfect womanhood, the dream of youth and the memory of maturity, which beckons toward the for ever unattainable. As a contribution to the physiology of genius, no other book is to be compared with the *Vita Nuova*. It is more important to the understanding of Dante as a poet than any other of his works. It shows him (and that in the midst of affairs demanding practical ability and presence of mind) capable of a depth of contemplative abstraction, equalling that of a Soofi who has passed the fourth step of initiation. It enables us in some sort to see how, from being the slave of his imaginative faculty, he rose by self-culture and force of will to that mastery of it which is art. We comprehend the *Commedia* better when we know that Dante could be an active, clear-headed politician and a mystic at the same time. Various dates have been assigned to the composition of the *Vita Nuova*. The earliest limit is fixed by the death of Beatrice in 1290 (though some of the poems are of even earlier date), and the book is commonly assumed to have been finished by 1295; Foscolo says 1294. But Professor Karl Witte, a high authority, extends the term as far as 1300 (*Dante Alighieri's lyrische Gedichte*, Leipzig, 1842, *Theil* ii. pp. 4–9). The title of the book also, *Vita Nuova*, has been diversely interpreted. Mr. Garrow, who published an English version of it at Florence in 1846, entitles it the "Early Life of Dante." Balbo understands it in the same way (*Vita*, p. 97). But we are strongly of the opinion that "New Life" is the interpretation sustained by the entire significance of the book itself. (*b.*) The treatise *De Monarchiâ*. It has been generally taken for granted that Dante was a Guelph in politics up to the time of his banishment, and that out of resentment he then became a violent Ghibelline. Not to speak of the consideration that there is no author whose life and works present so remarkable a unity and logical sequence as those of Dante, Professor Witte has drawn attention to a fact which alone is enough to demonstrate that the *De Monarchiâ* was written before 1300. That and the *Vita Nuova* are the only works of Dante in which no allusion whatever is made to his exile. That bitter thought was continually present to him. In the *Convito* it betrays itself often, and with touching unexpectedness. Even in the treatise *De Vulgari Eloquio*, he takes as one of his examples of style: "I have most pity for those, whosoever they are, that languish in exile, and revisit their country only in dreams." We have seen that the one decisive act of Dante's priorate was to expel from Florence the chiefs of both parties as the sowers of strife, and he tells us (*Parad.* xvii.) that he had formed a party by himself. The king of Saxony has well defined his political theory as being "an ideal Ghibellinism" (comment on *Parad.* vi.), and he has been accused of want of patriotism only by those short-sighted persons who cannot see beyond their own parish. Dante's want of faith in freedom was of the same kind with Milton's refusing (as Tacitus had done before) to confound license with liberty. The argument of the *De Monarchiâ* is briefly this: As the object of the individual man is the highest development of his faculties, so is it also with men united in societies. But the individual can only attain that highest development when all his powers are in absolute subjection to the intellect, and society only when it subjects its individual caprices to an intelligent head. This is the order of nature, as in families, and men have followed it in the organization of villages, towns, cities. Again, since God made man in his own image, men and societies most nearly resemble him in proportion as they approach unity. But as in all societies questions must arise, so there is need of a monarch for supreme arbiter. And only a universal monarch can be impartial enough for this, since kings of limited territories would always be liable to the temptation of private ends. With the internal policy of municipalities, commonwealths, and kingdoms, the monarch would have nothing to do, only interfering when there was danger of an infraction of the general peace. This is the doctrine of the first book, enforced sometimes eloquently, always logically, and with great fertility of illustration. It is an enlargement of some of the *obiter dicta* of the *Convito*. The earnestness with which peace is insisted on as a necessary postulate of civic well-being, shows what the experience had been out of which Dante had constructed his theory. It is to be looked on as a purely scholastic demonstration of a speculative thesis, in which the manifold exceptions and modifications essential in practical application are necessarily left aside. Dante almost forestalls the famous proposition of Calvin, "that it is possible to conceive a people without a prince, but not a prince without a people," when he says: *Non enim gens propter regem, sed e converso rex propter gentem.* And in his letter to the princes and peoples of Italy on the coming of Henry VII. he bids them "obey their prince, but so as freemen preserving their own constitutional forms." He says also expressly: *Animadvertendum sane, quod cum dicitur humanum genus potest regi per unum*

supremum principem, non sic intelligendum est ut ab illo uno prodire possint municipia et leges municipales. Habent namque nationes, regna, et civitates inter se proprietates quas legibus differentibus regulari oportet. Schlosser the historian compares Dante's system with that of the United States (*Dante, Studien*, &c., 1855, p. 144). It in some respects resembled more the constitution of the Netherlands under the supreme stadtholder, but parallels between ideal and actual institutions are always unsatisfactory. (Compare also Spinoza, *Tractat. polit.* cap. vi.) The second book is very curious. In it Dante endeavors to demonstrate the divine right of the Roman empire to universal sovereignty. One of his arguments is that Christ consented to be born under the reign of Augustus; another, that he assented to its jurisdiction in allowing himself to be crucified under a decree of one of its courts. The atonement could not have been accomplished unless Christ suffered under sentence of a court having jurisdiction, for otherwise his condemnation would have been an injustice, and not a penalty. Moreover, since all mankind was typified in the person of Christ, the court must have been one having jurisdiction over all mankind; and since he was delivered to Pilate, an officer of Tiberius, it must follow that the jurisdiction of Tiberius was universal. He draws an argument also from the wager of battle to prove that the Roman empire was divinely permitted, at least, if not instituted. For since it is admitted that God gives the victory, and since the Romans always won it, therefore it was God's will that the Romans should attain universal empire. In the third book, he endeavors to prove that the emperor holds by divine right, and not by permission of the pope. He assigns supremacy to the pope in spirituals, and to the emperor in temporals. This was a delicate subject, and though the king of Saxony (a Catholic) says that Dante did not overstep the limits of orthodoxy, it was on account of this part of the book that it was condemned as heretical. (*c.*) The treatise *De Vulgari Eloquio*. Though we have doubts whether we possess this book as Dante wrote it, inclining rather to think that it is a copy in some parts textually exact, in others an abstract, there can be no question either of its great glossological value, or that it conveys the opinions of Dante. We put it next in order, though written later than the *Convito*, only because, like the *De Monarchiâ*, it is written in Latin. It is a proof of the national instinct of Dante, and of his confidence in his genius, that he should have chosen to write all his greatest works in what was deemed by scholars a *patois*, but which he more than any other man made a classic language. Had he intended the *De Monarchiâ* for a political pamphlet, he would certainly not have composed it in the dialect of the few. The *De Vulgari Eloquio* was to have been in 4 books. Whether it was ever finished or not, it is impossible to say, but only 2 books have come down to us. It treats of poetizing in the vulgar tongue, and of the different dialects of Italy. The Florentines have denied its authenticity, because it does not allow the supremacy of the Tuscan. From the particularity with which it treats of the dialect of Bologna, it has been supposed to have been written in that city, or at least to furnish an argument in favor of Dante's having at some time studied there. In lib. ii. cap. 2, is a remarkable passage in which, defining the various subjects of song and what had been treated in the vulgar tongue by different poets, he says that his own theme had been righteousness. (*d.*) The *Convito*. This also is imperfect. It was to have consisted of 14 treatises, but, as we have it, contains only 4. In the first he justifies the use of the vulgar idiom in preference to the Latin. In the other 3 he comments on 3 of his own *Canzoni*. It will be impossible to give an adequate analysis of this work in the limits allowed us. (A very good one may be found in the 6th volume of the Molini edition of Dante, pp. 391–433.) It is an epitome of the learning of that age, philosophical, theological, and scientific. As affording illustration of the *Commedia*, and of Dante's style of thought, it is invaluable. It is reckoned by his countrymen the first piece of Italian prose, and there are parts of it which still stand unmatched for eloquence and pathos. The Italians (even such a man as Cantu among the rest) find in it and a few passages of the *Commedia* the proof that Dante, as a natural philosopher, was wholly in advance of his age—that he had, among other things, anticipated Newton in the theory of gravitation. But this is as idle as the claim that Shakespeare had discovered the circulation of the blood before Harvey (see Field's "Theory of Colors"), and one might as well attempt to dethrone Newton because Chaucer speaks of the love which draws the apple to the earth. The truth is, that it was only as a poet that Dante was great and original (glory enough, surely, to have not more than two competitors), and in matters of science, as did all his contemporaries, sought the guiding hand of Aristotle like a child. Dante is assumed by many to have been a Platonist, but this is not true, in the strict sense of the word. Like all men of great imagination, he was an idealist, and so far a Platonist, as Shakespeare might be proved to have been by his sonnets. But Dante's direct acquaintance with Plato may be reckoned at zero, and we consider it as having strongly influenced his artistic development for the better, that, transcendentalist as he was by nature, so much so as to be in danger of lapsing into an oriental mysticism, his habits of thought should have been made precise and his genius disciplined by a mind so severely logical as that of Aristotle. This does not conflict with what we believe to be equally true, that the Platonizing commentaries on his poem, like that of Landino, are the most satisfactory. (*e.*) Beside the prose already mentioned, we have a small collection of Dante's letters, the recovery of the larger number of which we owe to Professor Witte. They are

all interesting, some of them especially so, as illustrating the prophetic character with which Dante invested himself. The longest is one addressed to Can Grande della Scala, explaining the intention of the *Commedia* and the method to be employed in its interpretation. The authenticity of this letter has been doubted, but is now generally admitted. (*f.*) The Poems. There is first a collection of minor poems, full of grace, and depth of mystic sentiment, and which would have given Dante a high place in the history of Italian literature, even had he written nothing else. They are so abstract, however, that without the extrinsic interest of having been written by the author of the *Commedia*, they would probably find few readers. All that is certainly known in regard to the *Commedia* is that it was composed during the 19 years which intervened between Dante's banishment and death. Attempts have been made to fix precisely the dates of the different parts, but without success, and the differences of opinion are bewildering. Foscolo has constructed an ingenious and forcible argument to show that no part of the poem was published before the author's death. The question depends somewhat on the meaning we attach to the word published. In an age of manuscript, the wide dispersion of a poem so long even as a single one of the 3 divisions of the *Commedia* would be accomplished very slowly. But it is difficult to account for the great fame which Dante enjoyed during the latter years of his life, unless we suppose that parts, at least, of his greatest work had been read or heard by a large number of persons. This need not, however, imply publication; and Witte, whose opinion is entitled to great consideration, supposes even the *Inferno* not to have been finished before 1314 or 1315. In a matter where certainty would be impossible, it is of little consequence to reproduce conjectural dates. In the letter to Can Grande before alluded to, Dante himself has stated the theme of his song. He says that "the literal subject of the whole work is the state of the soul after death simply considered. But if the work be taken allegorically, the subject is man, as by merit or demerit, through freedom of the will, he renders himself liable to the reward or punishment of justice." He tells us that the work is to be interpreted in a literal, allegorical, moral, and anagogical sense, a mode then commonly employed with the Scriptures,* and of which he gives the following example: "To make which mode of treatment more clear, it may be applied in the following verses: *In exitu Israel de Ægypto, domus Jacob de populo barbaro, facta est Judæa sanctificatio ejus, Israel potestas ejus.*† For if we look only at the literal sense, it signifies the going out of the children of Israel from Egypt in the time of Moses; if at the allegorical, it signifies our redemption through Christ; if at the moral, it signifies the conversion of the soul from the grief and misery of sin to a state of grace; and if at the anagogical, it signifies the passage of the blessed soul from the bondage of this corruption to the freedom of eternal glory." A Latin couplet, cited by one of the old commentators, puts the matter compactly together for us:

> *Litera* gesta refert; quid credas *allegoria;*
> *Moralis* quid agas; quid speres *anagogia.*

Dante tells us that he calls his poem a comedy because it has a fortunate ending, and gives its title thus: "Here begins the comedy of Dante Alighieri, a Florentine by birth, but not in morals."* The poem consists of 3 parts, Hell, Purgatory, and Paradise. Each part is divided into 33 cantos, in allusion to the years of the Saviour's life, for though the Hell contain 34, the 1st canto is merely introductory. In the form of the verse (triple rhyme) we may find an emblem of the Trinity, and in the 3 divisions, of the threefold state of man, sin, grace, and beatitude. Symbolic meanings reveal themselves, or make themselves suspected, everywhere, as in the architecture of the middle ages. An analysis of the poem would be out of place here, but we must say a few words of Dante's position as respects modern literature. If we except Wolfram von Eschenbach, he is the first Christian poet, the first (indeed we might say the only) one whose whole system of thought is colored in every finest fibre by a purely Christian theology. Lapse through sin, mediation, and redemption, these are the subjects of the 3 parts of the poem; or, otherwise stated, intellectual conviction of the result of sin, typified in Virgil (symbol also of that imperialism whose origin he sang); moral conversion after repentance, by divine grace, typified in Beatrice; reconciliation with God, and actual blinding vision of him—"the pure in heart shall see God." The model of the poem is that of the Christian basilica; the ethnic forecourt of those who know not God; the purgatorial middle space of repentance, confession, and absolution; the altar of reconciliation, beyond and over which hangs the emblem of the Mediator, of the divine made human, that the human might learn how to become divine. Here are general truths which any Christian may accept and find comfort in. But the poem comes nearer to us than this. It is the real history of a brother man, of a tempted, purified, and at last triumphant human soul; it teaches the benign ministry of sorrow, and that the ladder of that faith by which man climbs to the actual fruition of things not seen *ex quovis ligno non fit*, but only of the cross manfully borne. The poem is also, in a very intimate sense, an apotheosis of woman. Indeed, as Marvell's drop of dew mirrored the whole firmament, so we find in the *Commedia* the image of the middle ages, and the sentimental gyniolatry of chivalry, which was at best but skin-deep, is lifted in Beatrice to an ideal and universal plane. It is the same with Catholicism, with imperialism, with the scholastic philosophy; and nothing is more wonderful than the power of

* As by Dante himself in the *Convito.*
† Psalm cxiv. 1, 2.

* He commonly prefaced his letters with some such phrase as *exul immeritus.*

absorption and assimilation in this man, who could take up into himself the world that then was and reproduce it with such cosmopolitan truth to human nature, and to his own individuality, as to reduce all contemporary history to a mere comment on his vision. We protest, therefore, against the parochial criticism which would degrade Dante to a mere partisan, which sees in him a Luther before his time, and would clap the *bonnet rouge* upon his heavenly muse. Like all great artistic minds, Dante was essentially conservative, and, arriving precisely in that period of transition when church and empire were entering upon the modern epoch of thought, he strove to preserve both by presenting the theory of both in a pristine and ideal perfection. The whole nature of Dante was one of intense belief. There is proof upon proof that he believed himself invested with a divine mission. Like the Hebrew prophets with whose writings his whole soul was imbued, it was back to the old worship and the God of the fathers that he called his people; and not Isaiah himself was more destitute of that humor, that sense of ludicrous contrast, which is an essential in the composition of a destructive. In Dante's time, learning had something of a sacred character; the line was hardly yet drawn between the clerk and the possessor of supernatural powers; it was with the next generation, with the elegant Petrarch, even more truly than with the kindly Boccaccio, that the purely literary life, and that dilettantism which is the twin sister of scepticism, began. As a merely literary figure, the position of Dante is remarkable. Not only as respects thought, but as respects æsthetics also, his great poem stands as a monument on the boundary line between the ancient and modern. He not only marks, but is in himself, the transition. *Arma virumque cano*, that is the motto of classic song; the things of this world and great men. Dante says, *subjectum est homo*, not *vir;* my theme is man, not a man. The scene of the old epic and drama was in this world, and its catastrophe here; Dante lays his scene in the human soul, and his 5th act in the other world. He makes himself the protagonist of his own drama. In the *Commedia* for the first time Christianity wholly revolutionizes Art, and becomes its seminal principle. But æsthetically also, as well as morally, Dante stands between the old and new, and reconciles them. The theme of his poem is purely subjective, modern, what is called romantic; but its treatment is objective (almost to realism, here and there), and it is limited by a form of classic severity. In the same way he sums up in himself the two schools of modern poetry which had preceded him, and, while essentially lyrical in his subject, is epic in the handling of it. So also he combines the deeper and more abstract religious sentiment of the Teutonic races with the scientific precision and absolute systematism of the Romanic. In one respect Dante stands alone. While we can in some sort account for such representative men as Voltaire and Goethe (nay, even Shakespeare) by the intellectual and moral fermentation of the age in which they lived, Dante seems morally isolated and to have drawn his inspiration almost wholly from his own internal reserves. Of his mastery in style we need say little here. Of his mere language, nothing could be better than the expression of Rivarol: "His verse holds itself erect by the mere force of the substantive and verb, without the help of a single epithet." We will only add a word on what seems to us an extraordinary misapprehension of Coleridge, who disparages Dante by comparing his Lucifer with Milton's Satan. He seems to have forgotten that the precise measurements of Dante were not prosaic, but absolutely demanded by the nature of his poem. He is describing an actual journey, and his exactness makes a part of the verisimilitude. We read the "Paradise Lost" as a poem, the *Commedia* as a record of fact; and no one can read Dante without believing his story, for it is plain that he believed it himself. It is false æsthetics to confound the grandiose with the imaginative. Milton's angels are not to be compared with Dante's, at once real and supernatural; and the Deity of Milton is theologic, while nothing in all poetry approaches the imaginative grandeur of Dante's vision of God at the conclusion of the *Paradiso*. In all literary history there is no such figure as Dante, no such homogeneousness of life and works, such loyalty to idea, such sublime irrecognition of the unessential; and there is no moral more touching than that the contemporary recognition of such a nature, so endowed and so faithful to its endowment, should be summed up in the sentence of Florence: *Igne comburatur sic quod moriatur.*—In order to fix more precisely in the mind the place of Dante in relation to the history of thought, literature, and events, we subjoin a few dates: Dante born, 1265; end of crusades, death of St. Louis, 1270; Aquinas died, 1274; Bonaventura died, 1274; Giotto born, 1276; Albertus Magnus died, 1280; Sicilian vespers, 1282; death of Ugolino and Francesca da Rimini, 1282; death of Beatrice, 1290; Roger Bacon died, 1292; death of Cimabue, 1302; Dante's banishment, 1302; Petrarch born, 1304; Fra Dolcino burned, 1307; Pope Clement V. at Avignon, 1309; Templars suppressed, 1312; Boccaccio born, 1313; Dante died, 1321; Wycliffe born, 1324; Chaucer born, 1328.—The best authorities on the life and works of Dante are: Troya, *Il veltro allegorico* (Firenze, 1826); Arrivabene, *Il secolo di Dante* (Udine, 1827); Ugo Foscolo, *Discorso sul testo* (Lugano, 1827; and in 1st vol. Lond. ed. of Dante, 1843); Dante, edited with *Ottimo Comento* (Pisa, 1827–'29); ditto, edited by Ciarditti (5 vols. 8vo., Firenze, 1830; and 6 vols. 8vo., Molini, 1830); Rosetti, *Sullo spirito antipapale*, &c. (London, 1832); Colomb de Batines, *Bibliografia Dantesca* (Prato, 1845–'6); Balbo, *Vita di Dante* (Firenze, 1853); Witte, *Dante's lyrische Gedichte* (Leipsic, 1842); *Dante metrisch übertragen, etc., von Philalethes* [king of Saxony]

(2d ed., 3 vols. 4to., Dresden and Leipsic, 1849; containing the best notes and commentary hitherto); Wegele, *Dante's Leben und Werke* (Jena, 1852); Schlosser, *Studien*, &c. (Leipsic and Heidelberg, 1855); Bruce-Whyte, *Histoire des langues Romanes* (Paris, 1841, t. iii.); Aroux, *Dante, hérétique, révolutionnaire, et socialiste* (Paris, 1854); Fauriel, *Dante*, &c. (Paris, 1854); Ozanam, *Dante et la philosophie catholique*, &c. (3d. ed., Paris, 1855); Villemain, *Cours de littérature Français*, (Paris, 1855, t. i.); Quinet, *Les révolutions d'Italie*, &c., Paris, 1856; St. René Taillandier, in *Revue des deux mondes* for Dec. 1, 1856 (the best *resumé* of Dantean literature and criticism up to the present time); Carlyle, "Heroes in History" (London, 1841); Emerson, "Representative Men" (Boston, 1850); and Mariotti (Gallenga), "Fra Dolcino and his Times" (London, 1853). Of English translations, the most elegant is Cary's, though Dante is a little Miltonized in it. Cayley's preserves the original metre, the difficulty of which makes him sometimes obscure, often rugged; but, in parts, it is admirably Dantesque. John A. Carlyle has published a literal prose version of the *Inferno*, perhaps as good as any prose rendering of a poem remarkable for rhythm can be; his notes are good.

DANTON, Georges Jacques, a French revolutionist, born at Arcis-sur-Aube, Oct. 28, 1759, executed in Paris, April 5, 1794. A lawyer by profession, he became one of the most fervent champions of the revolution. He had some intercourse with Mirabeau, and while the latter was exercising his influence over the constituent assembly and the middle classes, he controlled the populace, whose affections he won by his fervid eloquence, energetic bearing, and cordial manners. One of the founders of the club of Cordeliers, in conjunction with Camille Desmoulins and Marat, he advocated the most violent measures. After the return of Louis XVI. from Varennes, Danton was one of the most ardent promoters of the petition for his deposition. This petition, presented for signature at a popular mass meeting, resulted (July 17, 1791) in the "slaughter of the Champ de Mars." Toward the end of the same year Danton was appointed a member of the administration of the Seine department, and assistant attorney of the common council of Paris. This official situation increased his ascendency, and he used it on every important occasion. He was foremost in organizing and conducting the attack of the people upon the Tuileries, Aug. 10, 1792; he eagerly participated in the fight; and a few days afterward he received, as a reward from the legislative assembly, his appointment to the ministry of justice. On the invasion of France by the Prussian army, which filled Paris with consternation, he showed such firmness and confidence that the assembly and the people were reassured; but at the same time he cried: "To stop the progress of the enemies, we must strike the royalists with terror!" A few hours later the mob broke into the prisons of Paris, and the dreadful "slaughters of September" ensued. Danton himself is said to have been instrumental in bringing about this bloody work; at any rate, it is certain he took no measure to prevent it. On being elected to the convention he resigned his office and became one of the leaders of that body. The death of the king was, in his eyes, a political necessity. "We have no right to be his judges, it is true," he said; "well, we will kill him." On his motion a levy of 300,000 men was ordered, and the revolutionary tribunal established, March 10, 1793. On the organization of the committee of public safety, April 6, he was appointed one of its members. Associating himself with Robespierre against the Girondists, he contributed to their fall, but he would willingly have spared their lives. In his opinion, the moment had come when rigor should yield to forbearance. Robespierre, however, did not agree with him, and availed himself of the occasion to rid himself of an ally whom he always had secretly hated. Branded as a *modéré*, Danton was seized at his house, March 31, 1794, and imprisoned at the Luxembourg. Some among the members of the convention desired to save him; but Robespierre, supported by St. Just, succeeded in obtaining from the assembly an indirect approval of the arrest; it was decreed that "in the name of virtue, terror was irrevocably the order of the day." Danton was arraigned with Camille Desmoulins, Lacroix, Fabre d'Églantine, and others of his friends, before the revolutionary tribunal; charged with having been the accomplice of all those enemies of the republic whom he had himself destroyed, he was not even allowed to put in a defence. He had himself instituted this tribunal, for doing which he now publicly begged pardon of God and man. "My object," said he, "was to prevent a new September, and not to let loose a scourge upon mankind. These Cains know nothing about government. I leave every thing in frightful disorder." The contempt with which he treated his judges hastened his sentence. On hearing it, he exclaimed: "We fall victims to some contemptible cowards, but they will not long enjoy their victory. Robespierre follows me; I drag him after me." On the road to the place of execution he preserved the most perfect composure, looking disdainfully at the mob that followed him with insults, and telling Camille to take no notice of such a vile rabble. Moved by the recollection of his wife, he shed a few tears, but immediately regaining his self-possession, said: "Be thyself, Danton; no weakness!" When he was about receiving the fatal blow, he said to the executioner: "You will show my head to the crowd; it is worth their seeing."

DANTZIC (Ger. *Danzig;* Pol. *Gdansk*), an administrative division of the province of West Prussia, extending about 100 m. along the Baltic, subdivided into 7 districts, containing 11 large and 6 small towns, and 1,875 villages; area, 3,222 sq. m.; pop. in 1855, 436,000. The principal river is the Vistula. The soil, sandy and

swampy in some parts, is generally productive. The area of woods and forests is estimated at 800,000 acres. The principal products are grain, fruits, and timber. The rearing of horses and cattle and the fisheries support a large number of the population. The chief manufactures are linen, woollen, leather, beer, and spirits.—The capital, DANTZIC, with a population in 1855 of 63,461, beside 8,800 soldiers, is an important fortress and commercial city, situated in lat. 54° 21′ N., long. 18° 39′ E., on the left bank of the principal arm of the Vistula, about 3½ m. from its mouth, with a circumference, including its 9 suburbs, of more than 12 m. The principal buildings are 3 citadels, the church of St. Mary, one of the largest in Europe, with a "Judgment Day" painted by Van Eyck; the *Catharinenkirche*, the council house, the government building, the old armory, the exchange, and 175 granaries and workshops on the Speicher (Granary) island, where no dwelling house is allowed, where no fire must be kindled, and where at night all streets are closed excepting one. There are 13 Protestant and 6 Catholic churches, a Mennonite church, and 5 synagogues. The city abounds with learned, charitable, and artistic institutions, and is celebrated for its monuments and antiquities, which have been recently (1857) described by Prof. Schultz. The harbor was excellent up to 1829 and 1840, when the Vistula broke above the city through the high ridge of the Downs, and formed a new outlet, reducing the depth of the old branch, so that a new port, Neufahrwasser, had to be built at its mouth, which is defended by 2 forts. The commerce of Dantzic was at an earlier period far more important than since the first partition of Poland, when the prohibitory tariff of Russia, the sound dues, the sufferings from the Napoleonic wars, the ascendency of Hamburg, Bremen, and Stettin, made it decline; but the last 10 years have given it a new impetus. The great staples are Polish and Prussian grain, especially wheat, and wood, leather, potash, wool, tallow, pitch, hemp, flax, butter, furs, beer, and liquors. In exports it is the first Prussian port; in imports, the second after Swinemünde. Ship-building is extensively carried on. Dantzic owns at present 115 sea-going vessels and 8 steamers, tonnage about 75,000. Entrances in 1854, 1,504; in 1855, 1,381; and in 1856, 1,429 vessels. Clearances in 1854, 1,500; in 1855, 1,305; and in 1856, 1,427 vessels. The value of the grain and seeds exported in 1856 is estimated at $2,700,000, and of the wood articles at $2,800,000. Of black beer 2,550 barrels, or 20,400 kegs, were shipped during the same year. The principal imports are coal (269 cargoes in 1856, against 190 in 1855), coffee, rice, guano, pepper, pimento, and herrings. Manufactures are gaining ground rapidly. Six steam sawing works, 2 oil mills, 30 distilleries of liquor (particularly *Danziger Goldwasser*), breweries, refineries of sugar, manufactories of tobacco, and other industrial establishments, are in a flourishing condition. The eastern Prussian railway connects Dantzic with Berlin and Königsberg, and a branch road with Posen, and new railroads are projected.—Dantzic was founded before the 10th century. In 1310 it fell under the sway of the order of Teutonic knights, and became a German city in the midst of a Polish population, and up to this day is not perfectly Germanized. In 1454 it subjected itself to the king of Poland, for the purpose of securing from him commercial privileges, became a free city with some very rich territory, and fell under the dominion of Prussia in 1793, after a struggle of 6 days. The siege by Lefèbvre, in 1807, after which it became a so-called free city under Napoleonic protection, with a strong French garrison, and the frightful siege in 1813 and 1814 (when Gen. Rapp made a famous defence of 12 months against the Prussians and Russians, and the city was half destroyed and the population half starved), the French war contributions and continental system, gave a severe blow to the prosperity of Dantzic; from which, however, it has since recovered, especially within the last few years, by the improvements in the river, by being made a station of the royal fleet, and above all by railway communication.

DANUBE (anc. *Danubius*, or, in its lower course, *Ister*; Ger. *Donau*), the largest river of Germany, and, next to the Volga, of Europe. It is formed by the confluence of 2 streams, Brege and Brigach, rising on the S. E. slope of the Black Forest, lat. 48° 6′ N., long. 8° 9′ E., about 24 m. from the Rhine, at an elevation of 2,874 feet above the level of the Black sea. In an air line the distance from the sources to the mouth of the Danube is nearly 1,020 m., while the length of its course is 1,770 m. The river system of the Danube and all its tributaries covers an area of 308,000 sq. m. In its course it traverses nearly 22° of longitude, and 8° of latitude. The elevation of its surface above the level of the sea is at Ulm, the head of steam navigation, 1,255 feet, at Donauwörth 1,160, at Ingolstadt 1,140, at Ratisbon 1,050, at Passau 800, at Linz 650, at Vienna 421, at Presburg 401, at Buda 348, near Zombor 272, at Moldova 200. Three principal divisions of the river basin are indicated by the character of the adjacent country, and the river itself: the upper course, terminating at Passau; the middle course, at Gladova; the lower one, at the mouth. In its upper course the Danube, flowing in an easterly direction, skirts the southern base of the sterile table-land of the Rough Alps (*Rauhe Alp*), the rapidity of its current being 5½ feet a second. Its breadth having increased to 230 feet, and its current slackened, it becomes navigable at Ulm. There, sweeping to the N. E., through the fertile Bavarian plain, it forms a curve, of which the northern apex is Ratisbon, and the eastern base Passau. On the N. side the Ludwigs-canal connects it with the Main and Rhine rivers. Near Passau the Bavarian forest on the one side, and the northern ranges of the Noric Alps on the other, approach the Danube, narrowing its bed in some places to 800 feet, while

in others it expands to a breadth of 5,000 feet. From Passau to Lintz the fall is 2¼ feet in a mile; from there to Vienna only 1¼ feet. In this portion of its course the scenery of the Danube fairly rivals that of the Rhine, and even excels it in sombre grandeur. Nearer Vienna the mountains recede from the banks, and the river enters a large plain, which, being but scantily protected by dikes, is subject to terrible inundations. Having once more passed between two mountain ranges, the Leytha on the southern and the lesser Carpathians on the northern bank, the Danube emerges into the fertile and well cultivated region of western Hungary. There, spreading out in several branches, it forms a great number of islands, among which the Great Schütt (50 m. long, and from 4 to 9 m. in width) and the Little Schütt (27 m. long) are the largest. Through a mountain defile, formed by the Neograd range of the Carpathians and the Bakony forest, the Danube enters the great Hungarian plain, turns abruptly to the S. near Waitzen, and slowly winds its course through vast level bottom lands and marshes, until it meets the Sirmian range, and, having received the waters of the Drave, is again deflected toward the S. E. It then skirts the plain on the S. till it arrives near Moldova, where it has to force its way through the Transylvanian granite hills and the Servian limestone range. This pass (Klysura), some 80 m. in length, offers the greatest obstacles to the navigation of the Danube. Narrowed down to 800 or 1,000 feet, less than one-half its former breadth, the river forms in 7 places between Alibeg and Gladova rapids and whirlpools, of which those in the so-called Iron Gate (*Demir Kapi*), below Old Orsova, are the most violent. There the river rages through a defile 7,200 feet long and 600 wide, with a fall of 16 feet, and a rapidity of 10 to 15 feet a second, over a number of reefs and ledges of rocks, defying, as it would seem, all efforts of man to subdue it. Still, after having been a terror to navigators for many centuries, the Iron Gate has at last been rendered navigable for steamers, a channel having been cut through the ledge by which vessels ply from Vienna to Galatz without a portage. In ancient times this portion of the river course was avoided by a canal, of which some vestiges still remain. Near Gladova the Danube leaves the mountains and enters the Bulgaro-Wallachian plains. From Cernetz to below Widin, it runs nearly S., then turns to the E. Slowly rolling its muddy waters round the extreme spurs of the Balkan, and forming numerous islands, it reaches a point only 32 m. distant from the sea, where it suddenly bends to the N. In this direction it flows upward of 100 m. to the junction with the Sereth; thence again eastward; at last, having been joined by the Pruth and divided into several branches, which sluggishly wind through a low and dreary alluvial country (the delta of the Danube), it empties into the Black sea by 3 principal channels (the Kilia, Sulina, and St. George's), and 4 lesser ones.—The most important tributaries of the Danube are, on the right or southern bank, the Iller, Lech, Isar, Inn, Traun, Enns, Leytha, Raab, Sárviz, Drave, Save, and Morava; on the left bank the Brenz, Warnitz, Altmühl, Naab, Regen, Itz, March, Waag, Neutra, Gran, Eypel, Theiss, Temes, Aluta, Ardshish, Jalomnitza, Sereth, and Pruth. The principal towns on its banks are, in Würtemberg, Ulm; in Bavaria, Ratisbon and Passau; in Austria proper, Lintz and Vienna; in Hungary, Presburg, Comorn, Gran, Buda, and Pesth; in the Military Frontier district, Peterwardein and Orsova; in Turkey, Belgrade, Widin, Nicopolis, Roostchook, Silistria, Hirsova, and Brahilov.—The Danube seems to be designed by nature as the connecting link of central Europe and the Orient, and has through all history been of great political importance. It was the channel through which the Mongolian element endeavored to overflow and suppress the feeble and not yet consolidated civilization of the Germanic races. For the Huns, the Avars, Bulgarians, Magyars, Tartars, and Turks, the Danube valley was the scene of their efforts to subdue the Occident. While the other great rivers of Europe, flowing in a northerly or southerly direction, formed barriers against the invasions of savage nations, the Danube, on the contrary, served as a highway from East to West. Hence, the ebb and flow of the great migration of nations subsequent to the downfall of the Roman empire were the strongest in the basin of the Danube, and for long centuries the fate of European civilization depended on the contest of races in that portion of the continent. The western nations having at last established their supremacy, the valley of the Danube was turned by them during the crusades into a highway toward the conquest of the Orient. But their progress in that direction was checked by the growing power of Mohammedanism, and for 2 centuries the countries bordering upon the Danube were again the theatre of a conflict, in which the Occident was frequently compelled to assume a defensive position. Within the last century the Mohammedan element has ceased to be dangerous to western Europe; but the Slavic element, occupying by its natural characteristics as well as geographically a middle position between the Occident and the Orient, has become formidable. Though baffled for the time being by the treaty of Paris (1856) in her designs against the countries adjacent to the lower course of the Danube, Russia has not ceased to exert her powerful influence on the Slavic races of Turkey and Austria. The difficulties in Montenegro and Bosnia, and the revolution in Servia (Dec. 1858), are the latest indications of the continuous pressure exerted by Russia in that direction. As yet, among the many races inhabiting the valley of the Danube, the German predominates as well in numbers as in intellectual culture. They occupy the entire upper basin, and portions of the middle and lower. The Slavic race, divided into many distinct tribes, and sub-

ject to different governments, is distributed along both banks of the middle course of the river. The Magyars also inhabit the central portion of the valley, while the Roumanians are the principal occupants of the lower regions. The entire population of the territory of which the Danube is the main artery is estimated at 40,000,000 (German 14,000,000, Slavic 12,000,000, Magyar 6,000,000, Wallachian 6,000,000, Italian, Turkish, Jewish, Armenian, gypsy, &c., 2,000,000).—The commercial importance of the Danube has scarcely begun to be developed. The rapidity of the current in its upper course, the reefs, rapids, whirlpools, sudden changes of the channel and banks, the shallowness of the river where it passes through the Hungarian plains, and its numerous windings, offered so many impediments to navigation, that up to a comparatively recent period it was limited to the scantiest intercourse between the provinces immediately adjoining the river. It is true that the physical obstacles to a successful navigation would have appeared less formidable if the political condition of the Danubian countries had been favorable to the development of a more extensive commerce. The application of steam as a motive power inaugurated a new era in the history of the Danube. Then the governments, becoming aware of the importance of the river, adopted a system of improvements. Reefs were removed, flats deepened by narrowing the channel, canals and cut-offs were constructed, and railroads built, in order to bring remote regions nearer this great artery of commerce. By the treaty of Paris (1856) the entire freedom of the navigation from tolls and dues was stipulated for; and in pursuance of this, the governments of the states through which the river flows agreed upon a convention (Nov. 7, 1857), by which vessels of all nations are allowed to ascend the Danube from its mouth to any point above, while the navigation between different points on the river is reserved to the subjects of the ripuarian states. The principal drawback to the importance of the Danube as a channel of commerce is the shallowness of its mouths. The 3 outlets enclosing the delta (or rather 3 flat islands, Chetal, Leti, and Moïshe, the highest elevation of which is not more than 6 or 7 feet above the level of the sea), the Kilia Boghasi, Sulina Boghasi, and Kediskeh Boghasi (St. George's channel), have a length of 72, 53, and 55 m. respectively. Formerly the St. George's channel was used almost exclusively; but having been choked with sand by the simultaneous occurrence of a strong freshet in the river and a violent gale from the sea, it was abandoned, and the Sulina channel resorted to. The Turkish government took good care to keep this channel open; but when, by the treaties of 1812 and 1829, the mouths of the Danube passed under the control of Russia, all efforts in that direction ceased; indeed, it was said that in order to benefit the commerce of Odessa, Russia rather increased than diminished the natural obstructions of the Sulina mouth. This, however, has been denied. The bar of the Sulina continues 1,000 yards outside of the mouth; it has a width of 2 to 3 m., and a depth of water varying from 10 to 14 feet. It is asserted that dredging can never permanently avail on a bar extending far into the sea, and that the erection of 2 large breakwaters from 5,000 to 6,000 yards long will prove the only means of effectually removing the obstruction. However this may be, the energetic efforts made by the Austrian government immediately after the retreat of the Russians (1854) have at last succeeded so far as to obtain an available average depth of 10 feet, while under Russian rule the depth had been reduced to 7½ feet. By the treaty of Paris an international committee was appointed for the regulation of the mouths of the Danube. The majority of this committee has concluded that it would be feasible to suppress or cut off 2 of the principal outlets, and, by leading their waters into the 3d, increase the volume and power of the current sufficiently to sweep away the mud and sand banks. A special committee, appointed by Austria, reported in 1857 that the St. George channel, if restored to its former condition, would, in all respects, offer the shortest and safest outlet, and that the cost of this improvement would not exceed 3,700,000 florins, nor the cost of keeping it in repair 65,000 florins per annum. It does not appear that as yet any thing has been done toward the realization of either scheme. Another scheme was started at the commencement of the last oriental war, viz.: the construction of a direct ship canal from that point of the Danube where it bends northward (Czernavoda) to the nearest point on the Black sea (Kustendji), thus substituting about 30 m. of artificial navigation for 185 m. of the river. This scheme was eagerly embraced by Austria, but it fell to the ground when a thorough exploration of the country proved the assumption on which the project was based to be erroneous. A sandstone ridge, 10 m. wide, and the lowest point of which is 164 feet above the level of the sea, extends along the belt of land which would have to be traversed by the canal. The Danube and its principal tributaries (the Inn, Drave, Theiss, Save) are navigated by steam vessels for an aggregate length of 2,400 m. The Bavarian Danube steam navigation company was established in 1838, that of Würtemberg in 1843. The Austrian Danube steam navigation company in 1857 employed 102 steamboats and 330 freight boats. Within the last 2 or 3 years, however, the net receipts of the company have not been sufficient to pay the interest on the capital, and the government has been obliged to cover the deficiency.

DANVERS, a post township of Essex co., Mass., with manufactories of railroad cars, coaches, leather, boots and shoes, carpets, &c.; capital employed in manufactures in 1855, over $150,000; hands employed, 3,000. In 1855 Danvers was divided by the incorporation of South Danvers as a separate town; pop. of the former in 1855, 4,000, of the latter 5,348. In 1852 Mr.

George Peabody of London, a native of this town, gave $20,000 (to which he afterward added $30,000) "for the promotion of knowledge and morality" among the inhabitants. With this donation the Peabody institute was founded, and enriched with a library; and a few years later the same gentleman appropriated $10,000 for the establishment of a branch library in North Danvers.

DANVILLE. I. A post borough and the capital of Montour co., Penn., on the North branch of the Susquehanna river, 12 m. above Sunbury, and 67 m. N. E. from Harrisburg; pop. in 1850, 3,302. It is actively engaged in the iron manufacture, for which it possesses every advantage, and contains one of the largest establishments for making railroad iron in the United States. Montour's ridge, extending nearly 21 m. along the river near this town, abounds in excellent iron ore, and in limestone, which is used as a flux in smelting. Rich mines of anthracite coal have also been opened in the vicinity, and the northern branch of the Pennsylvania canal affords means of transportation. The town contains 5 blast furnaces, 3 rolling mills, 2 founderies, 5 churches, an academy, a bank, and 2 weekly newspaper offices. A railroad from Philadelphia to Elmira, N. Y., passes through it. II. A post town, and the capital of Boyle co., Ky., on a small branch of Dick's river, 42 m. S. from Frankfort; pop. in 1854, about 2,650. Previous to 1792 it was the capital of the state. It is noted as the seat of the Danville (Presbyterian) theological seminary, which in 1857 had 4 professors and 36 students; of Centre college, founded in 1823, having in 1858, 5 professors, 180 students, and a library of 5,600 vols.; and of the state deaf and dumb asylum, containing about 70 inmates. A railroad connects it with Lexington.

DAPHNE, the name of a place near Antioch in Syria, containing a large and beautiful grove of laurels and cypresses, and a magnificent temple of Apollo. The grove was consecrated to this god by Seleucus Nicator. Antiochus Epiphanes built the temple, and other buildings sprung up around it. The most licentious scenes were enacted here, and the Roman general Cassius would not allow his soldiers to visit the place. When the emperor Julian came to Antioch the temple was almost deserted, and before he left the city it was consumed by fire, the work probably of some Christian incendiary. It was never rebuilt.

DAPHNE, a genus of ornamental plants, natives of the more temperate parts of Europe and Asia. Some are cultivated for beauty and fragrance, as the *D. odora;* others for a vivid green foliage, as the *D. laureola* of Britain; and others are useful in the arts. *D. mezereum*, a deciduous plant with white or purple fragrant flowers closely attached to the shoots, is the earliest blooming shrub of our gardens, the blossoms appearing in the beginning of April, before the leaves expand. This species, notwithstanding its beauty, has a dangerous reputation, the berries being used in Sweden to poison wild animals, and a very few of them when eaten by man are fatal. Its juice is acrid, and produces inflammation and even blisters upon the skin. The most curious property of the daphne is found in *D. lagetta*, or the lace tree of Jamaica, the inner bark of which, if macerated in water, is easily separated into thin layers, and has the texture and appearance of lace.

DAPHNEPHORIA (Gr. δαφνη, laurel), a Grecian festival celebrated every 9th year at Thebes, in honor of Apollo. For this a youth was chosen from one of the noble families of the city to be the daphnephorus or bearer of the laurel bough, and the priest of Apollo for that year. Behind him came a troop of maidens bearing boughs and singing hymns. The Delphians also had a custom of sending every 9th year a boy to pluck laurel boughs in the vale of Tempe, in commemoration of the purification of Apollo in that place after he had slain the Python.

DA PONTE, Lorenzo, an Italian poet, best known as the author of the lyrical dramas *Don Giovanni* and *Nozze di Figaro*, born at Ceneda, a small town in the Venetian states, March 10, 1749, died in New York, Aug. 17, 1838. His natural gifts having secured for him the protection of the bishop of his diocese, his education was well cared for. After filling for 2 years the office of professor of rhetoric in the seminary of Porto Guaro, he removed to Venice. Aspiring to an elective office in the state, he found an opponent in the celebrated Count Pisani, against whom he wrote a satirical sonnet, in consequence of which he was driven into exile. His next abode was in Vienna, where his merit procured for him the post of Latin secretary to the emperor Joseph II. He now commenced writing for the Italian theatres of Vienna and Prague, and produced the librettos of a number of operas for Salieri, Martini, and Mozart. After the death of the emperor Joseph, a green-room quarrel led to his second exile—this time to London. As poet and secretary of the Italian opera, then under the management of Taylor, he passed several years in the English metropolis; and "Kelly's Reminiscences" contains an interesting mention of him at this period of his life. In 1805 another turn in the wheel of fortune caused his emigration to America. Becoming naturalized in the United States, he thenceforth directed his energies to the diffusion of his native language and literature among the educated classes of New York. His efforts were crowned with success; and he was appointed, in his 80th year, to the professorship of his native tongue in Columbia college. He died in full communion with the Roman Catholic church. Beside various dramas, he is the author of memoirs of his own life, of a number of sonnets, and of translations of Byron's "Prophecy of Dante," and of Dodsley's "Economy of Human Life," all printed in New York. He also followed the precepts of his countryman Cornaro; he was a wise liver, and reaped his reward in a

long career of intellectual brightness, sustained to the last moment. Physically, he was powerfully constituted; possessing a tall and imposing form, and a head of antique beauty, with a profusion of flowing hair.—Lorenzo L., son of the preceding, and professor of belles-lettres in the university of New York, born in London in 1805, died in New York in 1841. He is the author of a valuable "History of the Florentine Republic" (2 vols. 8vo., New York, 1833).

DAPPES (*Vallée des Dappes*), a valley about 4 m. long and 2 broad in the Swiss canton of Vaud, on the S. W. slope of the Jura mountains. Its elevation above the level of the sea is 3,900 feet. A small stream from which the valley takes its name meanders through it. It is inhabited by 100 or 150 herdsmen. Without any value as a territorial possession, this valley has obtained some importance from the fact that it offers the most available military route from France to Savoy. In 1802 France annexed it, but Switzerland recovered possession in 1814 and maintained it, although the treaty of Vienna did not stipulate for its relinquishment by France. On several occasions France has endeavored to regain the valley, but has always been stoutly resisted by the Swiss confederation. The last of these conflicts occurred toward the end of 1858.

DARABGERD (Darab), capital of the district of the same name in the Persian province of Farsistan, lat. 26° N., long. 54° 50′ E.; pop. about 15,000. It was formerly a town of some extent, and there are many remains of antiquity, including the ruins of an aqueduct, some sculptured rocks, and a caravansary hollowed in the heart of a mountain. The town is situated at the foot of Mount Darakub, celebrated for producing *mumia nativa*, a species of liquid petroleum, which is believed by the Persians to possess a miraculous healing power.

D'ARBLAY, Madame. See Arblay, Madame d'.

DARCET, Jean, a French chemist, born in 1727, at Donazit (Landes), died in Paris, Feb. 13, 1801. From his earliest youth he studied chemistry, spent a fortune in the pursuit of his favorite science, and suffered for a time the privations of poverty while continuing his investigations. Having accepted the tutorship of the sons of Montesquieu, he became the intimate friend of that celebrated man, an associate in all his labors, and defended him in his last moments against the attacks of the Jesuits. After the death of Montesquieu he was induced to devote himself exclusively to chemistry. His experiments on the materials of porcelain and the modes of treating them in manufacture form an epoch in the history of the progress and improvement of the art, as practised at Sèvres. In 1770 he made his first communication to the academy of sciences, in which he explained his investigations into the chemical nature of precious stones, demonstrating the combustibility of the diamond. He discovered the method of extracting soda from marine salt; the means of manufacturing soap with any kind of grease or oil; the means of calcining calcareous earth; the means of improving various processes of dyeing; and also the means of more accurately assaying metals. He discovered what is called the "fusible alloy" of tin and bismuth. He also wrote an interesting paper on the means of extracting nutritive substances from bones. He was general inspector of the assay office of the mint at Paris, and of the manufacture of tapestry at the Gobelins. On the outbreak of the revolution he espoused its cause.

DARDANELLES, four castles or forts situated on the opposite shores of the Hellespont, or strait of the Dardanelles, which joins the archipelago to the sea of Marmora, and extends in a S.W. direction upward of 50 m. between lat. 40° and 40° 30′ N., and long. 26° and 27° E. The name is supposed to be derived from the ancient city of Dardanus. The Dardanelles are generally considered as the key of Constantinople, the access to which they are intended to command, but in several instances ships of war have passed them without serious injury. Thus in 1770 the Russian admiral Elphinstone, in 1801 Com. Bainbridge, in the American frigate George Washington, and in 1807 the British admiral Duckworth, sailed through the strait. The 2 castles at the entrance of the strait from the archipelago, Kumkale or Hissar Sultani on the Asian shore, and Sed-il-Bahr on the European shore, were built in 1658 by Mohammed IV.; they are in good repair, but inefficient in consequence of the width of the channel at that place (4¾ miles). The 2 old castles, Tchenekalessi or Boghaz Hissar, in Asia, and Kilid-il-Bahr in Europe, command the strait at a point where it is only 800 yards across, and may be closed by chains. The principal works of defence on the European side are 2 excellent coast batteries, Namasyah and Dagermen Burun. All the forts are well armed, though usually ill manned. Still, even if fully garrisoned, the castles and batteries, if unsupported by a field force, could hardly defend the passage of the strait. The bastions are open at the gorge, the batteries without casemates, and both are commanded by hills in the rear, thus requiring a strong movable column to repel a flank attack. Beside, a fleet stationed behind Cape Nagara would be indispensable in order to oppose the ships which might have succeeded in passing the forts and batteries. The town of Tchenekalessi is an indifferent place, containing about 2,000 houses. To the N. and E. from it a narrow strip of land projects into the sea. This is the site of the ancient Abydos, and a similar projecting point corresponds to it on the European shore. There Xerxes is supposed to have built his bridge uniting the 2 continents; there also Alexander the Great crossed into Asia; and there the crescent was for the second time planted on European soil by Solyman (1357). Here also Leander swam across the strait from Abydos to Sestos, to visit his beloved Hero, and Lord Byron and Lieut. Eckenhead swam the

same distance in 70 minutes (March 3, 1810). The Turkish government has always maintained the principle that no foreign vessel of war should be allowed at any time to pass the Dardanelles, and hence in the Egyptian war (1833) the British and French fleets were not permitted to enter the strait, though a Russian fleet from the Black sea was anchored at Buyukdereh. In 1841 the 5 great powers of Europe fully recognized this principle, and it was reaffirmed by the treaty of Paris in 1856. But in Nov. 1858, the U. S. frigate Wabash passed the Dardanelles and anchored at Constantinople, the commanding officer maintaining that the United States, being no party to the treaty of Paris, were not bound by its stipulations. Without acknowledging explicitly the correctness of this position, the Turkish government received the Wabash in a friendly spirit.—The so-called Lesser Dardanelles are 2 large castles situate on the capes Rhion and Antirrhion, in the gulf of Lepanto.

DARDANUS, according to the ancient legends, the ancestor of the Trojans. The Greek tradition was that he was a king in Arcadia, and that he went from that country to Samothrace, whence he afterward passed over into Asia Minor, and founded the town of Dardania. The Italian legend said that Dardanus was a native of Etruria, and from thence went to Samothrace and Phrygia.

DARDEN, Miles, probably the largest man on record, born in North Carolina in 1798, died in Henderson co., Tenn., Jan. 23, 1857. He was 7 feet and 6 inches high, and in 1845 weighed 871 lbs. At his death his weight was a little over 1,000 lbs. Until 1853 he was active and lively, and able to labor, but from that time was obliged to stay at home, or be hauled about in a two-horse wagon. In 1839 his coat was buttoned around 3 men, each of them weighing more than 200 lbs., who walked together in it across the square at Lexington. In 1850 it required 13½ yards of cloth, one yard wide, to make him a coat. His coffin was 8 feet long, 35 inches deep, 32 inches across the breast, 18 across the head, and 14 across the feet; and 24 yards of black velvet were requisite to cover its sides and lid. He was twice married, and his children are very large, though probably none of them will ever reach half the weight of their father.

DARE, Virginia, the first child of English parents in the new world, born at Roanoke in Aug. 1587, and named after the district of Virginia. She was the granddaughter of John White, who was governor of the colony sent by Sir Walter Raleigh to found an agricultural state, which sailed from Plymouth, April 26, 1587, and reached the shores of Virginia in July of the same year. White's daughter was married to Mr. Dare, who was one of the assistants of the governor, and Virginia was born about a month after the arrival of the expedition.

DARFOOR, Darfur, Darfour, Dar-Fur, or Dar-el-Fur, a country of central Africa, forming a large oasis in the S. E. corner of the great desert, bounded W. by Waday, S. by Fertit, and E. by a narrow strip of country inhabited by wandering Arabs, which separates it from Kordofan. It lies between lat. 11° and 16° N., long. 26° and 30° E., but its precise limits are not known; pop. estimated by Browne at 200,000, and by Mohammed Ebn-Omar-el-Tounsy at 3,000,000 or 4,000,000. The S. part of the country is hilly, and embraces many well-watered valleys; the N. consists chiefly of arid plains. The products of the soil are millet, rice, maize, sesamum, legumes, tobacco, medicinal plants, dye stuffs, and fruit. Cattle form the principal wealth of the people; camels, small elephants, and goats are numerous, and their flesh is used as food; horses and sheep are few and poor. The wild animals embrace the lion, leopard, hyena, wolf, jackal, rhinoceros, giraffe, hippopotamus, crocodile, and buffalo. Vultures, Guinea fowl, turtle doves, and chameleons are abundant. Among the mineral products are iron, copper, alabaster, marble, and nitre, the last of which is not used. The climate is excessively hot, and during the dry season the country is almost stripped of vegetation. The periodical rains last from the middle of June to the middle of September. The inhabitants are Arabs and negroes, professing the Mohammedan religion, but paying little regard to its stricter precepts; in morals and manners they are degraded to the lowest degree. They practise polygamy, and every species of labor except bearing arms is exacted of the women. The sovereign is a despotic sultan, whose court is encumbered with an absurdity of ceremonial seldom paralleled. He never speaks but through the mouth of an interpreter; when he spits, the spittle is gathered up by the hands of his attendants; if his horse stumbles while riding, or he loses his seat, every one of his retinue must do the same; and woe betide the courtier who when the sultan sneezes neglects to sneeze likewise. The royal body guard is composed of old women. Darfoor carries on some trade with upper Egypt in slaves, ivory, horn, ostrich feathers, gum, hides, drugs, copper, pimento, tamarinds, leathern sacks for water, parroquets, Guinea hens, and monkeys, in exchange for which it receives cotton cloths, glass ware, various trinkets and ornaments, coffee, spices, sugar, Indian merchandise, nails, metals, fruit, grain, firearms, other weapons, shoes, &c. The chief towns are Cobbe and Tendelty.

DARGAN, William, a public-spirited Irishman, born about 1801 in the county of Carlow, received a good education, was placed in a surveyor's office, and was afterward employed in various railway works. By his ability, industry, and integrity, he raised himself in the business of a railway contractor to a position of much influence, and to the possession of a great fortune. He is known to the public in consequence of his efforts in behalf of a national and universal exhibition of arts and manufactures at Dublin in 1853, in imitation of that at London in 1851. The money requisite for the execution of this project was advanced by Mr. Dargan, who at first

devoted £20,000 for the purpose, but at the time of the opening of the exhibition, May 12, his advances had reached nearly £100,000. He was to receive payment from the proceeds, but at the conclusion of the exhibition was left a loser to the extent of about £20,000. The queen offered him the honor of knighthood, which he declined.

DARIC, properly Daricus (Gr. Δαρεικος), an ancient Persian coin of pure gold, specimens of which are still preserved in several European collections, bearing on one side the image of a kneeling archer, on the other that of a royal palla. It was known to the Greeks, Romans, and Jews; the latter used it after the Babylonian captivity, under the reign of the Persians, and called it *adarcon* or *darkemon* (mentioned in the first book of Chronicles, by Esdras and Nehemiah). Its value was equal to 20 silver drachmæ, or 16*s.* 3*d.*; 3,000 being equal (according to Xenophon) to 10 talents. Its name is variously derived from that of King Darius Hystaspes, who regulated the Persian currency, and from several Persian words meaning king, palace, and bow. The so-called silver daries were not designated by this name in antiquity.

DARIEN, the capital of McIntosh co., Ga., on the left bank of the Altamaha river, 60 m. S. W. from Savannah, and 12 m. from the sea. It is a port of entry, and exports pine lumber. The shipping, June 30, 1852, was 306 tons registered, and 859 tons enrolled and licensed. Three vessels, tonnage 724, entered in 1852; clearances, 6 vessels, tonnage 1,359. It contains 5 churches and 1 academy. Pop. 600.

DARIEN, Colony of, had its origin in the energy of a Scotchman named Paterson, who, about the year 1680, set out on a visit to the new world. He was led in the course of his wanderings to the isthmus of Darien, where he met with Dampier and others of the buccaneers, then in the heyday of their glory. From their descriptions he obtained the notion of a country on the isthmus which had never been occupied by the Spaniards, fertile and arable, full of gold and precious metals, easy of access and defensible, with an excellent harbor, and rendered healthy and habitable to northern constitutions by a range of mountains which elevated it from the midst of the tropical heats into a delightful temperature. It was said also to occupy a situation where the passage between the oceans could be made in a day, and to be pointed out by nature for the highway of the commerce of the world. Hereupon he formed the plan of founding a colony there. His idea was to assemble under the protection of some powerful government an expedition large enough to acquire undisputed possession of the territory, and at the same time to carry with it the civil and religious institutions of the country from which they emigrated. In order to submit his project to the English government, he went to London, where he made the acquaintance of several eminent men, who found his ingenuity of advantage in framing the first law for establishing the bank of England; but in his own cause he met with less success, and his colonial project was discouraged. It was submitted successively to the Dutch, to Hamburg, and to the elector of Brandenburg; but finally, meeting with Fletcher of Saltoun, Paterson went on with him to Scotland, and there the project was adopted by the most powerful of the nobility. In June, 1695, a charter was procured from parliament, and ratified by the king, for a trading company to Africa and the new world, with power to plant colonies and build forts, with the consent of the inhabitants, in places not possessed by other European nations. Immediately people of all ranks and classes of society rushed to subscribe their names to the stock, and to obtain a share in the promising adventure. In a very short time the subscription amounted to £400,000, although at that time it was computed that there was not over £800,000 in cash in the whole kingdom of Scotland; and some gentlemen being deputed to receive subscriptions from abroad, £300,000 was taken by the English, and £200,000 by the Dutch. This flattering commencement, and the expectations excited by it, aroused the animosity of the East India company, through whose efforts some very severe measures against the enterprise were passed in the English parliament, and the Dutch, Hamburg, and London merchants withdrew their subscriptions. By the Scotch, however, this opposition, which was ascribed to envy, was looked upon as a more certain assurance of success. They took up the cause of the company unanimously as a nation, defended it by a powerful address to the king in parliament, and, although the poorest nation in Europe, proceeded to fit out the best appointed colony which had ever left the old world for the new. From the port of Leith 1,200 men sailed on July 26, 1698, in 5 stout ships, which it was almost impossible to disembarrass of the numbers who thronged on board anxious to join the expedition. They arrived at the isthmus in about 2 months. A large proportion of them were soldiers discharged from the wars of William III., under their own officers, and in a state of military discipline. Through the whole extent of Spanish America there was no force able to compete with them; but honorably and modestly adhering to their peaceful purpose, they commenced the foundation of a colony at a place called Acta, now marked on the map as Port Escoses, about 50 m. N. of the gulf of Darien. They gave it the name of New St. Andrew, and called the country New Caledonia. They began by purchasing lands of the natives, sent messages of amity to the nearest Spanish governors, and dug a passage for their ships across a neck of land to a safe harbor, while their first public act, adopted at the instance of Paterson, was to publish a declaration of freedom of trade and religion to all people. They had brought with them only a short supply of provisions, trusting to obtain what they needed from the Eng-

lish colonies. But the Dutch and English East India companies had united in procuring orders from the king forbidding any one to render them any assistance. Thus abandoned to the resources of the country, it was not long before disease made its appearance among them. In vain the hardy highlanders sought the coolest slopes of the mountains; in that fatal climate the colony was doomed. Paterson lingered for 8 months, waiting for assistance from Scotland, and not till almost all had died or departed did he consent to abandon the settlement, which he was himself the last to leave. In the mean time the efforts made in Scotland had brought together a reënforcement of 1,300 men, who were despatched in ignorance of the fate of the first party. The king of Spain had also presented at London his formal protest against the undertaking, and the Dutch had sent an address against it to King William. The second party, more hastily prepared than the first, was imperfectly organized; one of their vessels was lost at sea, many died on the passage, and those who arrived were dispirited by the original failure. They also brought with them 4 ministers appointed by the general assembly of Scotland to take charge of the souls of the colonists, and to set over them a faithful church, with its deacons, elders, and assembly, according to the national model. This work could not be carried out without interfering more or less with the government, and differences arose between the secular and ecclesiastical power, and the colonists became divided among themselves. The principal complaint made against the ministers was on account of the frequent days of fasting enjoined, and the length of the sermons and services, extending to 12 hours in the day. In addition to these domestic dissensions, foreign war came upon them. The attention of the Spanish government had been drawn to the danger of a successful settlement of another people and religion in the vicinity of their own territories, and within 3 months after their arrival the colonists received intelligence that a Spanish force of 1,600 men was waiting at Tubucantee for the arrival of a squadron of 11 ships, with which they were to be attacked. Luckily the last party which reached the colony was headed by a Capt. Campbell, who came in his own ship with a company of highlanders from his own estate, which he had commanded in Flanders. He was offered the command, and thinking the colony too feeble to await the attack, he set off the second day after his arrival, with a force of 200 men, for the Spanish camp, stormed it in the night, dispersed the hostile force, and was back again on the 5th day. But his expedition was in vain. On his return he found a Spanish squadron drawn up before the harbor, their troops landed, and all hope of retreat or aid cut off. The colonists endured, however, a siege of nearly 6 weeks, and were reduced to great extremities. When at last they capitulated, it was upon terms which not only obtained them the honors of war and inviolability of property, but even hostages for the performance of the conditions. Campbell, however, refused to be included in the capitulation to enemies whom he had injured so deeply, and succeeded in making his escape in his own vessel. He arrived safely in Scotland by way of New York, and his services were acknowledged by the present of a gold medal from the company. The rest of the colonists, worn out by labor and disease, were unable to weigh the anchor of the Rising Sun, their largest ship, which carried 60 guns. To their generous enemies they were indebted for this assistance, and again for preservation from shipwreck after they had gone ashore in getting out of the harbor. Their ships were so warped and leaky that the voyage toward home was long and distressed. Everywhere they received kindness from the Spaniards and inhospitality from their own kindred. The Rising Sun was wrecked on the bar of Charleston; only one small ship beside Capt. Campbell's was finally saved, and of the colony only about 30 survivors ever reached their native country. The destruction of this colony was a great blow to Scotland. Almost all the available resources of the nation had been embarked in it, and their loss for a long time made the national poverty more pinching. The manner in which it had been brought about, through the open and secret opposition of England and the Dutch, touched the national pride, and long embittered the feelings of the Scotch against their more opulent neighbor. Tales of the courage, of the disasters, and miserable fate of the colonists circulated in prose and verse over the country, and produced an appreciable effect among the causes of its subsequent unsettled state, and of the violent opposition to the union of the two kingdoms. Paterson himself, in whose brain the enterprise originated, was overcome by its failure. His labors and anxieties brought on a fever on his passage home, accompanied by alienation of mind. His native air, however, restored him, and, together with the directors of the unfortunate company, he made an effort to revive the attempt upon the footing of a joint stock company of £2,000,000, $\frac{4}{5}$ of which to be furnished by England and $\frac{1}{5}$ by Scotland. To this end he prepared an address and circular of great ability, setting forth the advantages of the project. It had the countenance of King William, but the obstacles in the way were too great to be overcome. An unsuccessful attempt was made to procure him some relief from the equivalent money finally paid at the time of the union by England to Scotland, in consideration of the losses of the Darien company.—See "Memoirs of Great Britain and Ireland," by Sir John Dalrymple, vol. ii., and Burton's "History of Scotland," London, 1853.

DARIEN, Gulf of, a portion of the Caribbean sea, on the N. coast of New Granada, in about lat. 9° N. and long. 78° W., bounded W. by the isthmus of Darien or Panama. It is about 26 leagues long from N. to S. by 9 from E. to W. Its shores are steep, generally inac-

cessible from shoals, and in some parts the anchorage is unsafe. It terminates at the S. in the bay of Choco, into which enters the river Atrato.

DARIEN, Isthmus of. See Panama.

DARIUS (Daryavesh in the Hebrew Scriptures; Darayavush in the Persian part of the great trilingual inscription at Behistun, on the western frontier of ancient Media). I. King of Persia, 521–485 B. C., was the son of Hystaspes, governor of Persis, of the royal race of the Achæmenidæ. He conspired with Otanes to dethrone the pseudo Smerdis, the Gomates of the Behistun inscription, who had been made by the magi king of Persia during the absence of Cambyses, and was, after the death of the usurper, the most fortunate of the 7 nobles of Persia who aspired to the throne, the choice having been decided, according to Herodotus, by the neighing of a horse. To strengthen himself on the throne, he married a daughter of Otanes, a daughter of Smerdis, and two daughters of Cyrus, one of whom, Atossa, attained great influence at his court. He was a monarch of great abilities, enterprising, despotic, and cruel, and may be regarded as the organizer of the Persian empire. He was a zealous adherent of the ancient Aryan or dualistic religion of his nation, and restored its prevalence over the rival creed of Magism. He divided Persia into 20 satrapies, determined the regular amount of their contributions, in produce or precious metals, for the government, army, and household of the king, and established regular communication by means of couriers between the 127 districts of the state, which extended from India to Ethiopia. One of his first military undertakings was a successful expedition to restore the island of Samos to Syloson, an ancient friend. The siege of Babylon, which revolted and defended its independence with the most desperate determination, lasted, according to Herodotus, 20 months; and it was conquered only by the savage self-sacrifice of Zopyrus, who having horribly mutilated his face went over into the besieged city, complained of the cruelty of the king, became the commander of the defending army, and betrayed it to Darius. The monarch wreaked his vengeance on the rebels, by impaling near 3,000 of the chief citizens, and destroying the gates and walls of the city (517). This narrative of the Greek historian, however, is not supported by the inscription of the monarch himself, according to which Babylon twice revolted from him. To chastise the Scythians around the northern shores of the Black sea, for ancient incursions to Asia, he started with 700,000 men from Susa, his capital, on an expedition to Europe, passed the Bosporus on a bridge built by a Samian Greek, traversed Thrace, crossed the Danube, following the nomads, who had only to retreat, driving their herds before them, and filling up the wells in their route, in order to conquer the invaders, without a battle, by famine and the hardships of an endless march through their inhospitable country. The greatest part of his army was lost when he returned, leaving the sick and the aged behind, and a body of troops under Megabazus in Thrace, which conquered the Pæones, and transplanted them to Phrygia. Thus a European country was annexed to the empire. Another expedition conquered a part of India, and the explorations down the Indus, and around the shores of the *Mare Erythræum*, under Scylax, a Carian Greek, even gained maritime glory for the monarch. The revolt of the Ionians, the support given them by the Athenians and Eretrians, and particularly the burning of Sardis (500), incited Darius to an expedition against Greece. After the conquest of Miletus, an army under Mardonius and a fleet were sent to subdue the Greeks; but the attacks of the Scythian tribes in Thrace, and tempests off Mount Athos, compelled both to return, and the Athenians rejected with scorn the demand for earth and water made by the heralds of the great king. Another army, sent with 600 vessels under the command of Datis and Artaphernes, conquered Naxos, but spared the sacred island of Delos (while the other Cyclades submitted without a struggle), destroyed the betrayed Eretria on the island of Eubœa, and landed in Attica. But the victory of the Athenians under Miltiades, at Marathon (490), defeated the army of Darius, though not his hope of subduing Greece. Arming again, and preparing the whole force of his empire, he was checked by a revolt in Egypt, soon after which he died, leaving the accomplishment of his designs of revenge to his son and successor Xerxes. Like Cyrus, Darius favored the Jews, and it was during his reign that they rebuilt the temple of Jerusalem. II. King of Persia, 423–405 B. C., called before his ascension to the throne Ochus, and surnamed by the Greeks Nothus, or the bastard. He became king by putting to death his natural brother Sogdianus, who had killed Xerxes II., the only legitimate son of Artaxerxes I. He was a weak prince, ruled by his queen Parysatis, a cunning and ambitious woman. His reign was disturbed by rebellions, among which that of Amyrtæus in Egypt was particularly successful. His governors in Asia Minor, Tissaphernes and Cyrus (the younger), his son, extended the influence of Persia in the affairs of Greece, which was distracted during his reign by the Peloponnesian war. His successor was his son Artaxerxes II. Mnemon. III. The last king of the ancient Persian monarchy (336–330 B. C.), raised to the throne by the eunuch Bagoas, after the murder of Arses, was a prince of mild and humane disposition, but inadequate to defend his empire against a conqueror like Alexander the Great, who shortly after his accession commenced the attack on Persia, passed the Hellespont, defeated the first army of Darius in the battle on the Granicus (334); the king himself at Issus (333), where his mother, wife, sister, and children were made captives, but treated with humanity; and, after the conquest of Syria and Egypt, in the battle of Arbela or Gaugamela in Assyria (331). The great armies of Persia were destroyed or scattered, and Da-

rius fled from province to province until he was overtaken by the Macedonians, when he was betrayed and mortally wounded by the faithless satrap Bessus. After having asked and received a draught of water, he expressed his gratitude to the giver, and to Alexander for the humane treatment of his kindred, and expired.

DARJEELING, or DARJILING, a British sanitary station in the territory of Sikkim, lieut. governorship of Bengal, situated near the junction of the rivers Runjeet and Teesta, at an elevation of 7,400 feet above the sea, 318 m. N. from Calcutta. It has a moist healthy climate, and is surrounded by fine mountain scenery. It was obtained from the rajah of Sikkim in 1835, and gave its name to a district which was enlarged in 1850 by the sequestration of adjacent tracts, and now comprises about 300 sq. m. In 1856 a company secured about 14,000 acres of land for the purpose of establishing a European agricultural settlement in this district.

DARKE, a W. co. of Ohio, bordering on Ind., intersected by 3 lines of railroad; area, 609 sq. m.; pop. in 1850, 20,274. The soil is fertile, and the surface generally level, occupied partly by prairies of no great extent, and partly by forests of beech, ash, walnut, hickory, and sugar maple. In 1850 the productions were 590,077 bushels of corn, 132,594 of wheat, 115,095 of oats, 11,519 tons of hay, and 390,443 lbs. of butter. There were 30 churches, 2 newspaper establishments, and 7,585 pupils attending public schools. The county was organized in 1809, and named in honor of Gen. William Darke. Capital, Greenville.

DARKE, WILLIAM, an American officer in the revolutionary war, born in Pennsylvania in 1736, removed in 1740 with his parents to Jefferson co., Va., and died there, Nov. 26, 1801. At 19 years of age he served with the Virginians in the battle of Braddock's defeat, and afterward in the war of the revolution. He was taken prisoner at the battle of Germantown, and was colonel commandant of the Hampshire and Berkeley regiments at the siege of Yorktown. At St. Clair's defeat he commanded the left wing of the army, and made two gallant and successful charges with the bayonet, in the second of which his youngest son, Capt. Joseph Darke, fell mortally wounded (Nov. 4, 1791). His father paused but a moment over him, and rushed with redoubled energy into the conflict. He was repeatedly a member of the Virginia legislature, and, as member of the convention of 1788, voted for the federal constitution.

DARLASTON, a town and parish of Staffordshire, England, with extensive mines of coal and iron, and manufactures of various articles of hardware. The ore obtained from the mines is here converted into iron of different kinds and of superior quality. Pop. of the parish in 1851, 10,590.

DARLEY, FELIX O. C., an American artist, born in Philadelphia, Penn., June 23, 1822. In boyhood he manifested a strong taste for art and an inclination to make it his profession. His parents, distrusting his ability to pursue such a career with success, placed him, when 14 years of age, in a large mercantile establishment, in the hope that his thoughts might be diverted into another channel. Darley, however, spent all his leisure hours in drawing, for which his predilection remained unaltered, and in which he made rapid improvement. Having shown some sketches of firemen, fishwomen, and other prominent types of city life, to the publisher of the "Saturday Museum," he was offered a handsome sum for them, and encouraged to rely wholly upon his pencil for support. For several years he was employed by large publishing houses in Philadelphia, and soon acquired a considerable reputation for the vigor and humor of his designs. The series published in the "Library of Humorous American Works" was very popular in the southern and western states. In 1848 he removed to New York, where he found ample occupation in illustrating the "Sketch Book," "Knickerbocker's New York," and various other publications. He had previously made a series of designs in outline from Judd's novel of "Margaret," without any definite intention of publishing them. The committee of the American art union having seen them, at once gave him a commission to illustrate in a similar style Irving's "Rip Van Winkle" for distribution among their subscribers. These designs, 6 in number, were followed the succeeding year by another set illustrating the same author's "Legend of Sleepy Hollow;" and the two series were recognized, both in the United States and England, as among the most creditable productions of the kind recently published. Offers were made to the artist to settle in London, which he declined. In 1856 his illustrations of "Margaret" were published in New York in a folio edition, amply confirming the expectations which had been raised by the long delay in their appearance. Of late years he has given much attention to the preparation of vignettes for bank notes, and is now engaged in illustrating an edition of Cooper's works in 32 vols., to contain upward of 500 designs. A large copy in crayons from one of these, representing the death of Scipio, in the "Red Rover," was in the exhibition of the American academy of design in 1858. His drawing of the massacre at Wyoming was published a few years ago, and 4 others, illustrating passages in American revolutionary history, are now in the hands of the engravers. For Irving's "Life of Washington" and Simms's novels he has also contributed many designs of this class of subjects. Among his last works is an illustration of the wedding procession in Longfellow's poem of the "Courtship of Miles Standish," which was published in New York in 1858–'9, in photographic form.

DARLEY, GEORGE, a British author, born in Dublin in 1785, died in London in 1849. He was graduated at Trinity college, Dublin, in 1811, went to London in 1825, and became attached to the "Literary Gazette" and "Athenæum" journals, in which his criticisms of poetry

and the fine arts gave him a favorable reputation in the literary world. He is the author of the "Labors of Idleness," "Silvia," and miscellaneous works of a mingled philosophical and poetic character. He was the editor of Moxon's edition of Beaumont and Fletcher, and also published an edition of Euclid, and other mathematical works.

DARLING, one of the principal rivers of central Australia. It is formed by the union of several small streams in the province of New South Wales, and during an irregular course through a barren country, receives the river Bogan from the S. E. Its waters are salt for a great distance above its mouth. It empties into Murray river.

DARLING, Grace, an English girl, celebrated for her heroic conduct in rescuing 9 persons from a shipwreck, born Nov. 24, 1815, at Bamborough, on the coast of Northumberland, died Oct. 20, 1842. Her father was keeper of the Longstone lighthouse, on one of the most exposed of the Farne islands. On the night of Sept. 6, 1838, the Forfarshire steamer, proceeding from Hull to Dundee, was wrecked upon one of the crags of the Farne group, with 53 persons on board, of whom 38 perished, including the captain and his wife. On the morning of the 7th the survivors were discovered by Grace clinging to the rocks and remnants of the vessel, and in imminent danger of being washed off by the returning tide. Grace, with the assistance, but against the remonstrances of her parents, who considered the undertaking desperate and hopeless, immediately launched a boat and succeeded in rescuing 9 of them, and 6 escaped by other means. Presents and demonstrations of admiration were showered upon her from all parts of the United Kingdom, and a public subscription to the amount of £700 was raised in her favor.

DARLING RANGE, a chain of granite mountains in western Australia, running parallel with the coast for a distance of 250 m. The highest summit has an elevation of 2,000 feet. The forests with which these mountains are clad contain sandal wood.

DARLINGTON, a N. E. district of S. C., in the alluvial region of the state, bounded N. E. by the Great Pedee, S. W. by Lynch's creek, and N. W. by Cedar creek; area, 800 sq. m.; pop. in 1850, 16,830, of whom 10,041 were slaves. Its river lands are of great fertility. The uplands are inferior, but occasionally well timbered. Large reclamations from the swamp borders of the Pedee, Lynch's, and Black river, have yielded vast bodies of the rich swamp lands to the hands of cultivation. The face of the country is undulatory, sometimes rising into hills of 300 feet. It has no mountains. The district is well watered. The Pedee is navigable by steamers its whole length, and Lynch's for 80 m. from its junction with the former river. Darlington, on Swift's creek, is the capital. It contains the usual public buildings, court house, gaol, &c., and about 1,500 inhabitants. The district is wholly agricultural; the staples are corn and cotton, and the productions in 1850 were 13,005 bales of cotton, 471,357 bushels of Indian corn, 61,916 of oats, and 119,283 of sweet potatoes. There were 14 grist and saw mills, 3 tanneries, 1 cotton factory, 26 churches, and 620 pupils attending public schools. The district is intersected by the Wilmington and Manchester railroad. It was settled by Virginians in 1750.

DARLINGTON, a municipal borough and market town of Durham, England, on the Skerne, 18 m. S. E. of Durham, and 235 m. by the great northern railway N. N. W. of London; pop. in 1851, 11,228. It is built in the form of a square, the centre being occupied by a market place, from which radiate several streets locally called gates. It is generally well built, and contains a Gothic church founded in 1160, two other churches, a number of chapels, a free grammar school, an academy founded by the society of Friends, a national school, a town hall, a central hall, several alms houses, a dispensary, a mechanics' institute, a public library, gas works, and a savings bank. The chief branches of industry are the carding and spinning of wool, flax spinning, and the manufacture of carpets, brass, and iron. There is an extensive market for sheep and cattle every fortnight. The town is governed by a bailiff appointed by the bishop of Durham, and gives the title of earl to the duke of Cleaveland.

DARLINGTON, William, M.D., LL.D., an American botanist and politician, born of Quaker parents in Birmingham, Chester co., Penn., April 28, 1782. His early education was limited to that of a common country school, and his youth was passed in agricultural pursuits, until at the age of 18 he commenced the study of medicine with Dr. John Vaughan, in Wilmington, Del. He received the degree of M.D. from the university of Pennsylvania in 1804, and after passing 2 years at his father's house, devoted to the study of languages and botany, but gaining little practice, he went to Calcutta as surgeon on a merchant ship. A sketch of his voyage, in the form of 10 "Letters from Calcutta," was afterward published in the "Analectic Magazine." He returned from India in 1807, married, and for several years practised medicine successfully at West Chester. Here he soon entered into politics, and during the agitation which preceded the war of 1812 his pen was actively employed in defending the policy of Mr. Madison. On the breaking out of hostilities he aided in raising an armed corps in his neighborhood, and after the sack of Washington in 1814 was chosen major of a volunteer regiment, and elected by the democratic party to the 14th and afterward to the 16th and 17th congresses, where he gained reputation less as a debater than as a useful committee man. He took an active interest in the affairs of West Chester, and founded there an academy, an athenæum, and a prosperous society of natural history. In 1813 he had begun making a descriptive catalogue of plants growing around West Chester. This was

published in 1826 under the title of *Florula Cestrica*, and was afterward merged in a larger and more valuable work, the *Flora Cestrica*, published in 1837, and rewritten and republished in 1853, containing a complete description and classification of every plant known to exist in the county. In 1843 he edited the correspondence of his friend the late Dr. William Baldwin, and accompanied it with a memoir, the whole appearing under the title of *Reliquiæ Baldwinianæ*. In 1853 the name of *Darlingtonia Californica* was given in his honor by Dr. Torrey, of New York, to a new and remarkable variety of pitcher plant found in California.

DARMSTADT, the capital of the grand duchy of Hesse-Darmstadt, and of a circle of its own name (pop. 54,800), in the province of Starkenburg, situated on the small river Darm, 16 m. by railway from Frankfort-on-the-Main, and 30 m. N. from Mannheim and Heidelberg; pop. 27,200, mostly Protestants. The new part of the town contains beautiful streets and squares, and fine pleasure grounds. The remarkable buildings are the ducal palace (with a library of 300,000 vols.), the chancery, the diet house, the stable of the grand duke, the mint, the Catholic church, and the theatre of the court. There are galleries of pictures, of statuary and coins, a museum of natural history, 2 colleges, a gymnasium, various schools, a botanic garden, a military academy, an extensive armory, and many scientific and artistic societies. Among the charitable institutions are 2 for the benefit of poor young girls, for orphans and widows, and a deaconess institute established in 1857. The manufacturing interest is limited to linen and woollen fabrics, carpets, wax candles, musical, surgical, and mathematical instruments, colored paper, starch, and coaches. Darmstadt, which contained toward the close of last century only about 7,000 inhabitants, is greatly indebted for its growth to the grand duke Louis I., whose statue adorns the *Luisenplatz*. The *Theaterplatz* has contained since 1852 statues of Philip the Generous and George I. A bank of commerce and industry was established in 1854, and the bank for southern Germany (*Zettelbank*) in 1856. Public conventions have been often held in Darmstadt, and a *Zoll* congress in 1854. The principal journal is the *Darmstädter Zeitung*. Liebig, the chemist, was born in this town.

DARNEL (*lolium perenne*, Linn.), the ray or rye grass, has been recommended to be sown among other grasses on poor cold soils, and is spoken of as a pretty good pasture grass. Sir Humphry Davy has shown that in 1,000 parts 39 are nutritive matter, which is rather more than the foxtail (*alopecurus pratensis*) contains. The *L. temulentum*, or bearded darnel, is a noxious weed, and even poisonous qualities are attributed to the accidental use of its seeds occurring among other grain. This, the only poisonous grass known, is distinguished by its two-sided spikes and one-valved glumes. Neither is indigenous in America; the former from Europe has become naturalized; the other is an adventitious weed.

DARNLEY, Henry Stuart, lord, the 2d husband of Mary, queen of Scots, born in England in 1546, killed near Edinburgh, Feb. 9, 1567. He was the son of the exiled earl of Lennox by Margaret Douglas, daughter of the earl of Angus by Queen Margaret, widow of James IV. and sister of Henry VIII., and was therefore cousin german of Queen Mary, and a cousin of Queen Elizabeth. On his father's side he was descended from the royal line of Scotland. When Mary announced her intention of contracting a second marriage, Darnley, who possessed a handsome person and was skilled in many of the accomplishments of the age, went to Scotland to urge his suit, and was accepted. His marriage with Mary took place at Holyrood house, July 29, 1565, on which occasion she proclaimed him king, and promised to induce the Scottish parliament to grant him a crown matrimonial. He repaid her kindness by petulance and insolence, and open profligacy and infidelity; and finally alienated her affections by his participation in the murder of her secretary, the Italian singer, Rizzio. A few days afterward he had the meanness to denounce his confederates in this act, and aided Mary in driving them from the kingdom. He might even after this have become reconciled with the queen, but his vices and follies continually widened the breach between them. In Jan. 1567, while at Glasgow, he was taken ill with the small pox, and during his convalescence was removed to a solitary house called the Kirk of Field, near Edinburgh, from an apprehension that, if taken to Holyrood, he might communicate his disease to the young prince, then a few months old. The queen visited him here several times, and seemed to manifest some tenderness for him. On the night of Feb. 9 the house was blown up with gunpowder, and the dead bodies of Darnley and his servant were found lying uninjured near the ruins. The earl of Bothwell was the chief actor in this tragedy, and it has long been a moot point whether the queen was privy to it.

DARTER, a bird of the order *anseres*, family *pelecanidæ*, and genus *plotus* (Linn.). The bill in this genus is longer than the head, straight, and very slender, with sides much compressed to the acute tip, and the lateral margins finely serrated; the nostrils are scarcely visible; the wings are long, the 2d and 3d primaries the longest; the tail is long, of 12 feathers, and broad toward the end, which is rounded; the tarsi are short and strong; the toes long, united by a broad web, with short, sharp, and curved claws. Four species are described by Gray: *P. anhinga* (Linn.), in the southern states of North America; *P. melanogaster* (Gmel.), in Asia; *P. congensis* (Lecah), in Africa; and *P. Novæ Hollandiæ* (Gould), in Australia. They are peculiar to warm climates, where they live in society on fresh-water rivers and lakes. The first named species, the anhinga, or snake bird, or black-bellied darter, may be taken as the type of

the genus. The bill of this bird is about 3¼ inches long, the length to end of tail 36 inches, extent of wings 44 inches, tail 11½ inches, tarsus only 1½ inches; weight 3¼ lbs. The head is small, the neck very long and slender, and the body elongated; at the base of the upper mandible, around the eye, and on the throat, the skin is bare, and at the latter part dilated as in the cormorant. The plumage of the head, neck, and body is close and silky, with oblong rounded feathers; from near the eye to half down the neck on each side is a series of long, narrow, loose feathers; the scapulars are elongated, pointed, compact, and stiff. The upper mandible is olive, the lower yellow, with greenish tips; around the eye greenish, sac on throat orange, iris bright carmine; the general color of the head, neck, and body, glossy dark green, and of the scapulars, wings, and tail, bluish black; the long neck feathers are purplish white or lilac; at the lower part of the neck behind are numerous oblong small white spots, forming 2 broad bands as they extend backward; similar rows of white spots are seen on the smaller wing coverts; the first row of small, and the secondary coverts, are white; the tail is tipped with a band of brownish red, fading into white. In the female, which is smaller, the upper part of the head and the hind neck are dull greenish brown, and the fore part of the neck pale reddish brown with a grayish tinge, extending over the breast and ending abruptly in a reddish chestnut band; otherwise the colors are as in the male, except that the spots are less distinct, and that the fore part of the back has a brownish tint. In appearance and habits the darter resembles the cormorant, especially in the structure of the feet, wings, and tail; the bill is like that of the heron, as also is the neck, which forms the same sudden curvature between the 7th and 8th vertebræ. According to Audubon, there are no external nostrils in the adult, though they are found of small size in the young. This bird is a constant resident in Florida, and the lower parts of Louisiana, Alabama, and Georgia; in the spring they go as far up as North Carolina, breeding along the coast; in these various localities it goes by the names of water crow, Grecian lady, and cormorant. They arrive in the Carolinas from March to April, and remain until November, preferring rivers, lakes, and lagoons in the interior, in low situations and secluded spots; though sometimes seen near the sea, they are not known to fish in salt water; they do not like rapid streams or clear water, but delight in the slimy and stagnant pools of inaccessible morasses, where a few large and naked trees in the centre afford good stands for taking their prey or observing an enemy. From the character of the water they prefer, which would prevent their seeing a fish beneath its surface, they do not dive from an eminence or on the wing, like the fish hawk and king-fisher, but drop silently from the trees into the water, swimming about and diving from the surface like the cormorant. They are excellent swimmers, very light on the water when not afraid, but sinking all but the head and neck on the approach of an enemy; when swimming in the latter manner, the sinuous motions of the head and neck resemble the movements of a snake, whence the common name of snake bird. After securing a fish, the bird comes to the surface, throws it into the air if not too large, and swallows it whole, head first. Its food consists of various small fishes, crawfish, shrimps, young reptiles, aquatic insects, eggs of frogs, young leeches, &c., and in confinement even boiled maize. The quantity of fish they will consume is enormous; but like other flesh and fish eating birds, they can remain several days without food with impunity. The flesh is tough, oily, and unfit for food, except the small pectorals of the female. They are gregarious in the winter, fishing entirely by day, and fond of returning nightly to the same roosting places, which are always over water; they are not very shy in their favorite haunts, where they are seldom molested. Their flight is swift, well sustained, and often at an immense height, where they sail about in graceful curves, especially in the love season; on land they walk and run well, much better than the cormorant, holding the tail up, and darting the head about continually, distending the pouch, and uttering rough guttural sounds. As a diver it is unsurpassed by fresh-water birds, disappearing with the utmost quickness, and swimming beneath the surface for a long distance by means of the feet, the wings partially spread and the tail expanded. Asleep, they stand with the body nearly erect, with the head under the scapulars. In East Florida they breed toward the end of February, in Louisiana in April or May, and in South Carolina in June; Audubon supposes the same birds may breed twice a year in widely separated localities. The nest is made of sticks, is flattened in form, generally in tall water-surrounded cypresses; the eggs are 3 or 4, 2½ inches long, of a light blue color, covered with a whitish chalky substance. They attain their full plumage during the first year, and retain it through life. When wounded, the sharp bill is rather a formidable weapon of defence. According to Audubon, the quills and tail feathers, as in the cormorant, have the shaft hollow, even to the tip, with transparent walls of the same nature as the barrel, which last is the same as in other birds.

DARTFORD, a market town of Kent, England, on the Darent, 17 m. by the North Kent railway S. E. of London; pop. in 1851, 5,763. It is situated in a valley at a ford in the river, from which it takes its name, and consists chiefly of one wide street on the Dover road. It has a large ancient church, a number of chapels, several schools, an alms house, the ruins of a nunnery founded in 1371, a large iron foundery and machine shop, grain, oil, powder, paper, and cotton mills, calico and silk printing works, and gas works. The first mill for rolling and slitting iron established in England was in the neighborhood of this town. The river is navi-

gable from this point to its junction with the Thames. Dartford is noted in history as the residence of Wat Tyler.

DARTMOOR, a desolate tract of land in Devonshire, England, extending from N. to S. about 22 m., and from E. to W. 14 m., at an elevation of 1,700 feet above the sea; area estimated at about 150,000 acres. The surface is alternately swamp and barrens, producing a coarse grass on which cattle and sheep find a subsistence during the summer months. Numerous hills of granite, called *tors*, break the surface of the plain, and rise to a considerable elevation, Yes tor being 2,050 feet, and Cawsand Beacon hill 1,792 feet above the surrounding level. Of these tors, 150 are enumerated in Carrington's poem on Dartmoor. In the centre of the moor is an extensive swamp, in which the rivers Dart, Teign, Taw, Erme, Yealm, and 50 smaller streams, take their rise. The climate is at all times cold and moist. Storms from the Atlantic sweep over the moor, and it is difficult to imagine a more desolate spot during winter. A few scattered hamlets, occupied by quarrymen, contain the only population. Dartmoor is chiefly noted as the site of a prison, built in 1809, at a cost of £127,000, for the custody of French prisoners of war. At one time it contained 10,000 inmates. On the breaking out of hostilities with the United States in 1812, 2,500 impressed sailors, claiming to be American citizens, and refusing to serve in the British navy against their country, were imprisoned in Dartmoor, where most of them were kept till the end of the war. Accounts of the harshness of their treatment reached the United States, and created much feeling. This was especially the case on an occasion when the guard fired upon the prisoners. Explanations, however, have shown that the occurrence was the result of a mistake. The Dartmoor prison enclosures occupy an area of 30 acres, encircled by a double line of lofty walls. In 1850 the prison was fitted for the reception of convicts. Experiments made in cultivating the moor by the labor of the convicts have proved satisfactory. Over 100 acres around the prison are now under crop. About one-half the annual expense of maintaining the institution is repaid by the industrial employments of the inmates.—Dartmoor offers considerable attraction to the tourist and naturalist. Druidical remains may be traced. The greater part of the tract was afforested under the name of Dartmoor forest by King John. Under Edward III. it was united to the duchy of Cornwall.

DARTMOUTH, a municipal and parliamentary borough, seaport, and market town of Devonshire, England, on the W. shore of a bay formed by the Dart at its entrance into the English channel, 32 m. S. W. of Exeter; pop. in 1851, 4,508. It is built on the side of a hill, which is so steep that the base of the houses in the upper street is but little below the chimney pots of those in the street below. The ascent is facilitated by flights of steps. The thoroughfares are dirty, irregular, and narrow, but are lighted with gas. Many of the houses are very old, and display some fine specimens of wood-carving. The town contains 3 churches, several chapels, schools, and alms houses, a market place, and remains of a castle supposed to be of the reign of Henry VII. The harbor, which is entered by a narrow channel between the fort and battery of St. Petrox and the old castle, is safe, convenient, and large enough to accommodate 500 ships. A great many vessels belonging to this port were formerly engaged in the Newfoundland fisheries, but this branch of industry has greatly declined. Ship building, rope making, and paper making are carried on to some extent; there is an export trade in woollen goods, cider, and barley, in exchange for wine, oil, salt, and fruit; and slate and limestone are quarried in the neighborhood. The number of vessels registered as belonging to the port, Dec. 31, 1856, was 398, tonnage 34,987; number of vessels entered during the year 757, tonnage 39,969; number of vessels cleared 391, tonnage 19,026. During the civil wars the town was twice captured, once by the royalists, and once by the parliamentarians. It returns one member to the house of commons, and gives the title of earl to the Legge family. It is one of the quarantine ports of the channel.

DARTMOUTH COLLEGE, a seat of learning in Hanover, N. H., which received its charter in 1769, and went into operation in the following year under the presidency of Eleazar Wheelock, D.D. It grew out of an earlier school established by the Rev. Mr. Wheelock in Lebanon, Conn., and designed for the education of Indian children. The idea of this school had been suggested to him by his success in educating a young Mohegan Indian, Samson Occom, who became a remarkable preacher. Other pupils from the Delaware tribe were afterward received, and the school became an object of public attention and interest. In 1754, a farmer named Joshua Moor gave a house and two acres of land for the purposes of the institution, which was from this time known as Moor's Indian charity school. Occom, accompanied by the Rev. Nathaniel Whitaker, visited England to collect funds; a sum of about £10,000 was subscribed, and a board of trustees was there organized, of which Lord Dartmouth, one of the subscribers, was made president. The school was so much resorted to by the native tribes that Dr. Wheelock determined to transfer it to some place nearer to them. Many proffers of situations were extended to him, but he selected the town of Hanover, on the Connecticut river, in the western part of the state of New Hampshire, and grants of about 44,000 acres of land were made to him. The institution was chartered by Gov. Wentworth under the name of a college, with all the privileges and immunities of any university within the British realm; and the name of Lord Dartmouth was adopted for it. Moor's school soon afterward obtained an independant charter, and still remains as an academical or preparatory

department. In 1770 Dr. Wheelock removed his family and school, consisting of 18 whites and 6 Indians, from Lebanon to the wilderness of Hanover, where the whole colony lived in log huts. In 1771 the first class of 4 students was graduated. President Wheelock retained his office till his death in 1779, and was succeeded by his son John Wheelock, who in 1782 was sent by the trustees to Europe to promote the interests of the college; and through introductions by Gen. Washington, Dr. Franklin, and John Adams, he obtained considerable sums of money, philosophical instruments, and other valuable donations. The prince of Orange was one of the donors. He returned in 1784, and after a presidency of 36 years, was removed from the office by the trustees in 1815. This act, which was occasioned chiefly by a local religious controversy, led to a conflict with the legislature of the state; that body claimed the right to amend a charter of which it was the guardian, and in 1816 passed acts creating a new corporation in which the property was vested, and changing the title of the college to Dartmouth university. The old trustees began a suit for the recovery of the college property, which was decided against them in the supreme court of the state. It was carried by appeal before Chief Justice Marshall in the supreme court of the United States, where the judgment was reversed, and the principle of the inviolability of chartered property fully established. It was by his elaborate argument in behalf of the plaintiffs in this case that Daniel Webster, at the age of 35, took rank among the most distinguished jurists in the country. "He opened his cause," says Mr. Ticknor, "with perfect simplicity in the general statement of its facts, and then went on to unfold the topics of his argument in a lucid order, which made every position sustain every other. The logic and the law were rendered irresistible. As he advanced, his heart warmed to the subject and the occasion. Thoughts and feelings that had grown old with his best affections rose unbidden to his lips. He remembered that the institution he was defending was the one where his own youth had been nurtured; and the moral tenderness and beauty this gave to the grandeur of his thoughts, the sort of religious sensibility it imparted to his urgent appeals and demands for the stern fulfilment of what law and justice required, wrought up the whole audience to an extraordinary state of excitement." Webster was associated in this case with Jeremiah Smith and Jeremiah Mason, and opposed to John Holmes of Maine, William Pinkney, and William Wirt. The question excited also a violent controversy in the local newspapers. Wheelock was raised to the presidency of the university by the new board, in Feb. 1817, but died within two months, and was succeeded by William Allen, D.D., who retained the office till the decision of the question in favor of the college by the supreme court, in 1819. Francis Brown, D.D., was the successor of Wheelock as president of the college, having been elected by the old board in 1815, and retained the office till his death in 1820. He was succeeded in the presidency by the Rev. Daniel Dana, who, after one year, was succeeded by Bennet Tyler, D.D.; upon whose resignation in 1828, Nathan Lord, D.D., the present incumbent, received the appointment. The college comprises also a medical school, and the Chandler scientific school, the latter of which went into operation in 1852, being founded by a donation of $50,000 from Abiel Chandler, to give instruction in the practical and useful arts of life, as mechanics, engineering, architecture, drawing, and the modern languages. In 1858–'9 there were 50 students in the medical school, and 44 in the scientific. The faculty of the college consists of the president and 16 professors. The whole number of alumni is 4,365, and the present number of undergraduates (1859) is 260. The different libraries connected with the college have an aggregate of about 34,000 volumes. An astronomical observatory, of excellent design and furniture, has lately been erected through the munificence of George C. Shattuck.

DARU, Pierre Antoine Noël Bruno, count, a French statesman and author, born at Montpellier, Jan. 12, 1767, died near Meulan, Sept. 5, 1829. He studied with excellent success under the Oratorians of Tournon, devoted himself to literature, producing poems and translations, most of which remain unpublished, and from 1784 to 1791 was commissary of war. Adopting the principles of the revolution, he served as ordnance commissary in the army of Brittany, but was suspected and imprisoned during the reign of terror, recovered his liberty on the 9th Thermidor, in 1796 entered into the ministry of war under Petiet, soon after became chief commissary, and during this period pursued his literary studies, publishing in 1797 a translation of Horace. After the return of Napoleon from Egypt, he was nominated inspector of the troops and secretary of the ministry of war, was elected tribune in 1802, and under the empire in 1805 and 1806 became counsellor of state, superintendent-general of the house of Napoleon, superintendent-general of the grand army, and member of the French academy. He was charged with the execution of the treaties of Marengo, Presburg, and Tilsit, was then sent as plenipotentiary to Berlin, and after the battles of Eckmühl and Wagram joined the emperor at Ratisbon, followed him to Vienna, and was there appointed to execute the treaty of Vienna and to administer the Austrian states. He opposed the alliance of the emperor by marriage with any of the royal families of Europe, maintaining that his throne was founded on different principles from theirs. In 1811, as minister of state, the whole administration of the empire rested upon him; and in the next year he strongly opposed the Russian campaign, in which as superintendent-general of the army he displayed all the resources of his courage and talent. He was one of the last to give adher-

ence to the restablished Bourbons, and was among the first who rallied about Napoleon when he reappeared from Elba. Retiring from public life after the battle of Waterloo, he composed at Bourges and on his estate near Meulan his *Histoire de Vénise* (7 vols., Paris, 1819; 3d ed., 1827), one of the most thorough and interesting works on the subject; and in 1819 was recalled from exile, entered the chamber of peers, took his place on the left, and until his death was an eloquent opponent of the reactionary tendencies of the government. He was as indefatigable in literature as in administrative affairs, and published several elegant poems and satirical epistles, *Éloges* of Sully, Volney, and Laplace, a *Histoire de Bretagne* (Paris, 1826), and reports on the rupture of the treaty of Amiens, the monetary system, public instruction, the right of petition, individual liberty, and the censorship of the press.—Two of his sons, Napoleon and Victor Paul, were prominent in French politics prior to the establishment of the present empire.

DARWAR, or Dharwar, a district of the Bombay presidency, British India, bounded N. by Belgaum, E. by the Nizam's territory and Bellary, S. by Mysore, and W. by North Canara; area, 3,837 sq. m.; pop. 754,385. The soil and climate are adapted to the growth of cotton, and in 1842 the New Orleans species of that plant was introduced with such success, that in 1851 nearly 43,000 acres of it were under cultivation. The cotton is shipped at Coomta, from which the principal marts are 80 or 100 m. distant. The district formed part of the ancient kingdom of Bejapoor, and was overrun by Sevajee in 1675, and by HyderAli in 1777. It is comprised in the region known as the South Mahratta country, but nearly all the inhabitants are Canarese. It was acquired by the British on the overthrow of the Peishwa in 1818.—Darwar, the chief town of the above district, is situated near the W. frontier, 70 m. E. from Goa, and 288 S. E. from Bombay. It is defended by a wall and ditch, and a fortress originally strong, but now much decayed. It is the seat of 3 government schools, one Mahratta, one Canarese, and one English. It was captured by Hyder Ali in 1778, and retaken by the British and Mahrattas in 1791.

DARWEN OVER, a town of Lancashire, England; pop. in 1851, 11,702. It is laid out with little regularity, but is well built, rapidly improving, and supplied with gas and abundance of water. The principal branches of industry pursued here are the cotton manufactures, paper making and staining, silk weaving, and carpet making. The cotton mills, which are the most extensive establishments of the town, contain 3,800 looms and 63,000 spindles.

DARWIN, Charles, an English naturalist, was engaged on board the Beagle, Capt. Fitzroy, in that officer's exploring expedition, 1832 to 1836. On his return he published several works, principally records of his experience, and of the geological and physiological results of his travels and observations. Among these are the "Voyage of a Naturalist;" "Journal of Researches into the Geology and Natural History of the various Countries visited by H. M. S. Beagle;" "Geological Observations on South America;" numerous papers on the islands of Polynesia and Australia, published in the "Proceedings of the Geological Society;" and a "Monograph of the Family Cirripedia," a work of extraordinary scientific ability, published by the Ray society, and distributed to their members in 1851–'53.

DARWIN, Erasmus, an English physiologist and poet, born at Elton, Nottinghamshire, Dec. 12, 1731, died at Derby, April 18, 1802. He studied at Cambridge, was graduated at Edinburgh, and settled as a physician at Lichfield. The work by which he is best known is the "Botanic Garden," a poem in 2 books, the first explaining the economy of vegetation, the 2d personifying "the loves of the plants." Gnomes, sylphs, nymphs, and salamanders were adopted to give machinery to the poem. He next published "Zoonomia, or Laws of Organic Life," a curious physiological essay. In 1800 he published "Phytologia, or Philosophy of Agriculture and Gardening;" also "Letters on Female Education," addressed to his daughters. A poem, entitled the "Temple of Nature," appeared after his death (1803). Darwin's writings had a large popularity in their day. Miss Seward, in 1804, published his memoirs.

DASH, N. Cisterne de'Courtiras de Saint Mars, viscountess, better known under the title of countess, a literary French woman, born in Paris about 1805, received an excellent education, was married at an early age, and subsequently, owing to pecuniary reverses, adopted literature as a profession. She has written about 40 novels, of which not fewer than 13 appeared between 1853 and 1857.

DASHKOFF, Ekaterina Romanovna, a Russian princess, born in 1744, died near Moscow, Jan. 4, 1810. She was the 3d daughter of Count Roman Woronzoff, received a literary education, and was at an early age attached to the person of the future empress, Catharine II. In her 16th year she married Prince Dashkoff, with whom she lived for some time in Moscow, and then returned to the court, where her sister Elizabeth had become the favorite of the new emperor, Peter III., while his wife Catharine was treated with insulting brutality. Indignant at the insolence of her sister, and the unworthy situation of her friend, whose ambition, passions, and love of study were congenial to hers, she became, at the age of 18, the soul of a conspiracy which deprived Peter of his throne and life, and made his German wife the autocrat of Russia. The means she employed to strengthen this conspiracy were often the opposite of pure; and at the execution, dressed in male costume and mounted on horseback, she commanded a body of soldiers. But the scanty rewards the empress bestowed upon her by no means answered the expectations of the princess; her request to receive the command of the imperial

guard was refused, and her independence of character and bluntness of manners soon deprived her of the imperial friendship and favor. Retired from court, she devoted herself to study and the society of scholars; and after the death of her husband, she travelled through the west of Europe, where she made the acquaintance of many celebrated men of the age. Among others, she visited Voltaire at Ferney in 1771. On her return to St. Petersburg in 1782, she met with a more favorable disposition on the part of the empress, who appointed her to the presidency of the academy of sciences, and in 1784 to that of the new Russian academy, established upon her proposition in imitation of the French academy. She took an active part in the elaboration of the great Russian dictionary, which was completed according to her plan. She also wrote plays, and contributions in prose and verse for periodicals, and edited a monthly magazine. After the death of Catharine (1796), she was commanded by her successor, Paul, who was no admirer of the acts of his mother, to retire to a poor village in the government of Novgorod, "where she could meditate on the events of 1762." The intercession of her friends finally released her from this exile, and she spent the last years of her life on an estate near Moscow. The "Memoirs of the Princess Daschkaw, Lady of Honor to Catharine II., edited from the Originals by Mrs. Bradford" (2 vols. 8vo., London, 1840), were written after a manuscript of the princess which has been destroyed.

DASYA, a beautiful genus of the red-seeded marine algæ, of which there are several species peculiar to this country. The pear-shaped spores or seeds are borne upon the smaller branches in ovate conceptacles. *D. elegans* is found upon the New England coasts.

DATCHET, a pleasant village of Buckinghamshire, England, on the Thames, opposite Windsor, much resorted to in summer by anglers and other pleasure seekers; pop. in 1851, 898. It is renowned as the scene of Sir John Falstaff's adventure with the "merry wives of Windsor" on Datchet mead.

DATE PALM, the *phœnix* of botanists, the Greek name of the date, probably from the word Phœnicia, from which country the best dates were brought. It grows abundantly in Egypt, Arabia, Persia, and the neighboring countries, contributing largely to the support of the inhabitants. *P. dactylifera* is a lofty palm. Scarcely any other vegetable enters so largely into the uses of man. A single date palm will bear upward of 1 cwt., and sometimes between 2 and 3 cwt., of dates in a season. Camels are fed upon the abortive fruit and the ground date stones. From the leaves are manufactured couches, baskets, bags, mats, brushes, &c.; from the trunk, fences for gardens, and fuel. The fibrous parts of the bases of the leaves afford thread to spin into ropes and rigging, and the sap is capable of fermentation for beverage. Even the young shoots are used as a delicate vegetable resembling asparagus, and the central pith yields a sort of starch of nutritive properties. Other species are known to botanists, but this is the most useful to man.

DATE PLUM (*diospyros*, Linn.), better known in the western states of this country as the persimmon. Like this, the fruit of all the date plums are small and at first astringent, but sweet and edible when ripe. *D. lotus* bears a fruit of the size of a cherry; *D. discolor* of the Philippine islands produces a fine fruit; and *D. Kaki* of Japan bears fruit of the size of an apricot, which is dried as a sweetmeat by the Chinese. Most of these plants are tropical.

DATISCA, a genus of plants related to the nettles, indigenous to the south of Europe. The *D. cannabina* is a large, coarse, perennial, herbaceous plant, its juices possessing a bitter, tonic property, and the fibres of its stalks resembling those of hemp. Its flowers are borne in clusters in the axils of the bracts, and are of no particular beauty.

DATIVE, in grammar, the 3d case in the declension of nouns, expressing the state or relation of a thing to which some other thing is attributed or conferred. It derives its name from the passive participle of the Latin verb meaning "to give," and designates a relation corresponding to that expressed in English by the prepositions *to* and *for*. Thus in the phrase, "to give peace to the republic," the word "republic" would in the classic languages be put in the dative case without a preposition.

DATURA, a genus of rank, poisonous, narcotic plants, having showy flowers, some of which possess fragrance as well as beauty. The word *datura* is said to be derived from the Arabic *tâtórah*, which indicates the oriental origin of the herb. The most common is an Asiatic or perhaps tropical American species known as thorn apple (*D. tatula*), found about waste grounds near dwellings. This is considered as a variety of *D. stramonium*, whose blossoms are white, and growing near the sea-shores. The leaves and the seeds of the stramonium are officinal. From the green capsules and ripe seeds an alkaline extract is obtained, called daturia, which crystallizes from its solution in alcohol or water into colorless, shining, aggregated prisms. This is very poisonous. Stramonium produces delirium, and even maniacal symptoms. The delirium is peculiar, disposing to ridiculous exhibitions. The dried leaves, when smoked like tobacco, have been recommended in the treatment of asthma, sometimes with benefit, and the plant has even acquired great reputation. *D. fastuosa* has a polished, purple stalk, large leaves, beautiful flowers, of a rich purple color outside, pure satiny white within, of an agreeable odor, sometimes also having semi-double blossoms. The odor of *D. Wrightii* is also pleasant; its flowers are large, of a creamy white, delicately tinted with violet as they fade. *D. arborea*, now *Brugmansia*, is one of the greatest ornaments of gardens; its flowers are trumpet-shaped, nearly a foot in length, coming out of the division of the branches, of a pale yellow-

ish color outside and white within, and diffusing a delightful fragrance in the open air. They are all raised from seeds or propagated by cuttings, and even the roots of the herbaceous kinds survive by protecting them from severe frosts.

DAUB, Karl, a German theologian, born in Cassel, March 20, 1765, studied in Marburg, and was professor of theology in Heidelberg from 1794 to his death, Nov. 22, 1836. He wrote *Theologumena* (Heidelberg, 1806) under the influence of Schelling's philosophy; "Judas Iscariot," a treatise on the origin of moral evil (Heidelberg, 1816); "Theological and Philosophical Lectures" (7 vols., Berlin, 1838–'44); and "Hypotheses in regard to the Freedom of the Will" (Altona, 1834), a valuable criticism on the different theories concerning the nature and freedom of the will.

DAUBENTON, Louis Jean Marie, a French naturalist, born at Montbar, Côte d'Or, May 29, 1716, died in Paris, Jan. 1, 1800. His father destined him for the church, and sent him to Paris to study theology; but he secretly devoted himself to medicine. The death of his father left him free to follow his inclination, and he took his medical degrees at Rheims in 1740 and 1741. Buffon, who had taken charge of the *jardin des plantes*, required at that time an assistant of an observing spirit and a skilful hand, content to occupy a secondary position, as it were the eye and hand of his governing mind; and such an assistant he found in his old schoolmate Daubenton. The prudence of the latter, added to the strength of his associate, gave to their joint work on quadrupeds a completeness and accuracy which could hardly have been expected at that time; as Cuvier says, Daubenton was useful to Buffon, not so much for what he did for him, as for that which he prevented him from doing. He went to Paris about 1742, and was made demonstrator and keeper of the cabinet of natural history in 1745; his salary was at first only $150 per annum, but by degrees it was raised to $800, with certain perquisites and free lodgings. While carrying out zealously the views of Buffon, he was also laying the foundation for his own fame as a naturalist. It is principally to Daubenton that France owes its cabinets of natural history at the *jardin des plantes*. Before his time this collection was little more than a drug-shop; in the course of a few years he increased the specimens in every department a hundred fold, arranged and named them; discovered and perfected processes for the preservation of organic matters; mounted birds and quadrupeds in the most natural manner, displaying every characteristic. The study and arrangement of these objects became the all-absorbing passion of his life; and toward the end of his career, when the victories of Napoleon brought a great accession of specimens, he was often seen in the museum; even in his 84th year, with bent body and gouty extremities, he was supported daily in his visit to the mineralogical cabinet, the only portion which remained in his charge under the new organization. In the "History of Quadrupeds" are given descriptions of the external and internal organs of 182 species, of which 58 had never before been dissected, and 13 not previously described; there are also external descriptions of 26 species, of which 5 were unknown; the arrangement and character of the descriptions are excellent; the innumerable new facts presented bearing upon internal structure may be considered as the first attempt in France to place comparative anatomy upon a basis of observation. The appearance of this work brought him great fame, and at the same time not a little annoyance. Réaumur at that time stood at the head of the list of naturalists, which position he deserved for his observations on insects; he was considerably alarmed, then, to find himself in danger of being eclipsed by these new rivals, whose novel views and captivating style excited the attention of the public. While Daubenton was receiving the homage of naturalists, Buffon was fêted and praised at court; and some of the flatterers of the latter persuaded him that he would do better to dispense with the services of his scientific associate. This advice Buffon followed in his 8vo. edition of the *Histoire naturelle* (13 vols.), from which he cut out all the anatomical details and descriptions of animals contributed by Daubenton; the history of birds and of minerals he also wrote alone. The regrets of naturalists at the inferior and inaccurate execution of these subsequent works of Buffon must have been a great consolation to Daubenton, who, beside the affront thus put upon him, lost an income of $2,400 a year. In order to retain his situation at the *jardin des plantes*, he forgot the insult and the loss, and quietly continued his labors. So completely indeed did he forget Buffon's injustice, that he contributed to many parts of the work, without attaching his name to his labors; and it is certain that Buffon used his manuscripts in his "History of Minerals." Their intimacy was afterward revived, and was interrupted only at the death of Buffon. During the 18 years of the publication of the 4to. edition of the "History of Quadrupeds," Daubenton contributed but little to the memoirs of the academy; but after that period he wrote much in the publications of the academy, of the institute, and of medical and agricultural societies. He discovered 6 new species of mammals common in France; he first applied his knowledge of comparative anatomy to the determination of fossil remains of quadrupeds; he gave the characteristic differences between man and monkeys; he made many valuable additions to the sciences of mineralogy and vegetable physiology; his contributions to agriculture and rural economy were so valuable, and made his name so popular among the masses, that he had no difficulty in retaining his position of director of the national museum through the stormy period of the revolution, which menaced even the life of many naturalists. In 1773, at his suggestion, one of the chairs of practical medicine in the college of France was changed into one of natural history, and he was appointed to

fill it in 1775; and in 1783 he lectured on rural economy at the veterinary college of Alfort. Disappointed under the old *régime*, he obtained from the national convention the conversion of the cabinets of the *jardin des plantes* into a special school of natural history, in which he was appointed professor of mineralogy; he discharged the duties of this office until his death, keeping fully up with the progress of this rapidly advancing science; even at the age of 80 he took delight in explaining to his classes the brilliant discoveries of Haüy, his former pupil. He gave a few lectures at the normal school during its brief existence, always exciting the greatest enthusiasm in his numerous audience. He contributed to the *Encyclopédie méthodique* the articles on quadrupeds, reptiles, and fishes, remarkable for their exactness and clearness; he was also engaged in editing the *Journal des savans*. With a feeble constitution, and always at work, he arrived at an advanced age without painful infirmities; this was owing to a careful study of himself, and the avoidance of all excesses of body or mind; his regimen was temperate and uniform; always enjoying the comforts of life, he cared not for fame or fortune, and was peculiarly free from that vanity and love of approbation which has been the stumbling block in the path of so many illustrious men. His studies were for him rather an amusement than a task; a portion of his time was daily devoted to reading with his wife romances and other light literature, which he called "putting his mind on diet." This relaxation from labor, and the regularity of his habits, contributed much to that amenity which rendered his society so agreeable. He had naturally a good opinion of his fellows; having had but little intercourse with the world, and absorbed in the contemplation of nature, his mind, so acute in the detection of scientific error, could never suspect falsehood in man when presented under a pleasing exterior. Chosen a member of the senate in Dec. 1799, Daubenton wished to perform the duties of his office; being obliged to change the routine of his simple habits and to expose himself at a rigorous season of the year, on his first meeting with the senate he was seized with apoplexy, and fell senseless into the arms of his colleagues; notwithstanding the most prompt and scientific medical assistance, he regained consciousness only for a few moments, during which he displayed the greatest calmness, indicating the progress of the paralysis which was soon to prove fatal. His funeral was attended by citizens of all ranks, ages, and professions, anxious to show the last tribute of respect to a public benefactor. His remains were interred in the *jardin des plantes*, which he loved so well, and which he may be almost said to have created; on the eastern slope of a hill near the conservatories is a granite column, supported on a base of other mineral products, which marks his grave.

DAUBENY, Charles Giles Bridle, an English natural philosopher, born in Gloucestershire, distinguished for his researches in chemistry, which have been especially directed to elucidate the phenomena exhibited by volcanoes and the growth of plants. One of his first publications was "An Essay on the Geology and Chemical Phenomena of Volcanoes" (1824). His principal work on the same subject is entitled "A Description of Active and Extinct Volcanoes" (2d edition, 1848). The subject led him to investigate the composition of mineral and thermal waters. He visited the United States in 1837, and directed his observations particularly to mineral springs, of which, and of the geology of North America, he published accounts in the papers of the Ashmolean society and of the British association in 1838. His papers upon the volcanoes of Italy, and the extinct volcanoes of central France, possess great geological interest, from the application of the principles enunciated to explain the changes taking place in the interior. He proposed the theory of the bases of the earths existing in a metallic state, and by their oxidation giving rise to the phenomena of volcanic fires. Those upon the chemical actions exhibited in the growth of plants display a similar talent in original investigation.

D'AUBIGNÉ. See Aubigné, Merle d'.

DAUDIN, François Marie, a French naturalist, born in Paris, March 25, 1774, died in 1804. His most valuable work is *Histoire naturelle générale et particulière des reptiles, pour faire suite à l'Histoire naturelle de Buffon* (8 vols. 8vo., 1802–'4).

DAULIS, a city of ancient Greece, in Phocis, near the confines of Bœotia, destroyed by the Persians during their second invasion of Hellas, and subsequently by Alexander the Great. But its strong position on the summit of a lofty hill rendering it important as a military station, it was rebuilt, and survived till the Christian era. Daulis is famous in mythology as the scene of the tragic events contained in the myths of Tereus, Procne, and Philomela. Its ruins are still to be seen near the modern village of Dhavlia.

DAUMAS, Melchior Joseph Eugène, a French general, born Sept. 4, 1803, distinguished for his military services in Algeria, and still more for the important part which his familiarity with the language and characteristics of the native population enabled him to take in the administration of the colonial government. After his return to France he was intrusted (April, 1850) with the direction of Algerian affairs in the ministry of war. He published in conjunction with M. Ausone de Chancel a comprehensive work on the southern portion of the French colonies in Algeria, *Le Sahara Algérien* (Paris, 1845); and in concert with M. Fabar (who died in 1849 during the siege of Rome), *La grande Kabylie, études historiques* (1847). He has also supplied the leading French reviews with valuable information on the same subject, and written many other works on Algeria, the most important of which are *Principes généraux du cavalier Arabe* (4th ed. 1855), trans-

lated into German; *Mœurs et coutumes de l'Algérie* (3d ed. 1857, 18mo.); and *Les chevaux du Sahara* (4th ed. 1857), translated into Spanish and German.

DAUMER, Georg Friedrich, a German poet and philosophical writer, born at Nuremberg, March 5, 1800, studied at the gymnasium of his native city, at that time under the direction of Hegel, and subsequently at the universities of Erlangen, where Schelling was his professor of philosophy, and of Leipsic, devoting himself first to theology, but soon after to philosophy. He officiated as professor at the gymnasium of Nuremberg, from about 1822 to 1830, when he was obliged to tender his resignation in consequence of ill health, and afterward devoted himself exclusively to literary labors. His works, some of which have appeared under the *noms de plume* of Amadeus Ottokar and Eusebius Emmeran, are less remarkable for their originality than for the boldness and anti-christian tendency of his theories, which are chiefly based upon the systems of Schelling and Hegel.

DAUMIER, Henri, a French artist, one of the contributors to the Paris *Charivari*, born in Marseilles in 1810. Among his best efforts are his illustrations of "Robert Macaire" and his caricatures of the politicians of 1848 (*Représentants représentés*, and *Idylles parlémentaires*).

DAUN, Leopold Joseph Maria von, count, generalissimo of the imperial troops in the 7 years' war, born in Vienna, April 25, 1705, died Feb. 5, 1766. He took a distinguished part in the war against the Turks (1737–'39) and in the Silesian wars (1740–'41 and 1744–'45). In the 7 years' war he won the battles of Collin (1757) and Hochkirch (1758), and captured in Saxony the Prussian general Fink, with 11,000 Prussians (1759). Laudon lost the same year the battle of Liegnitz, because Daun failed to relieve him; and Daun lost the battle of Torgau (1760), after having won it in the daytime, by Ziethen's cavalry attack at night, and was himself wounded.

DAUNOU, Pierre Claude François, a French scholar and politician, born at Boulogne-sur-Mer, Aug. 18, 1761, died at Paris, June 20, 1840. At 16 he entered the order of the Oratorians, and taught literature, philosophy, and theology in several of their colleges. In 1792 he was elected to the national convention by the department of Pas-de-Calais, in conjunction with Carnot and Thomas Paine. He denied the right of the convention to try Louis XVI., and voted for his detention only. On the fall of the Girondists he signed a protest against the illegal proceedings of May 31, in consequence of which he was arrested. He resumed his seat after the 9th Thermidor, and took a conspicuous part in the framing of the constitution of the year III. On the establishment of the directory, he entered the council of 500, of which he was the first president. In 1797 he went to Italy, where he participated in the organization of the Roman republic. He was reëlected to the council of 500 in 1798, and was a member of the committee appointed after the 18th Brumaire to prepare, in conjunction with the provisional consuls, the new constitution of the year VIII. He declined a seat in the council of state offered to him by Bonaparte, and became a member of the tribunate; but his independence of character caused him to be ejected from this body in 1802. In 1804 he was appointed keeper of the archives of the legislative body, and in 1807 of those of France, which office was taken from him in 1815 by the Bourbons, and restored to him in 1830 by Louis Philippe. In 1818 he was made professor of history and morals in the college of France, and elected to the chamber of deputies, and became a peer in 1839. His publications, which are mostly historical, are distinguished by thorough learning, keen criticism, and a perspicuous style. Among his principal works are his continuation of Rulhière's *Histoire de l'anarchie de Pologne; Essai historique sur la puissance temporelle des papes;* and *Cours d'études historiques*, an invaluable repertory of knowledge, published after his death. He was also an important contributor to the *Journal des savans*.

DAUPHIN, the title of the eldest son of the king of France, heir presumptive of the crown. The title descended also to his eldest son, as after the death of the grand dauphin, son of Louis XIV., but not to the king's brother. The official designation was: "By the grace of God, eldest son of the king of France, and dauphin of Viennois." It was first connected with the reigning family upon the cession of the province of Dauphiné, April 23, 1349, made by Humbert of Viennois (whose ancestors, according to some historians, early in the 12th century assumed the dolphin as their device or symbol, whence the title), to Charles (afterward Charles V.), grandson of Philip VI., on condition that the eldest sons of the king of France should thenceforth bear the title of dauphin. The last dauphin was Louis Antoine, duc d'Angoulême, who took the title on the accession of his father Charles X. to the throne. After the abdication of Charles X. he also abdicated in favor of his nephew the duc de Bordeaux. The seigneurs of the house of Auvergne were also called dauphins d'Auvergne, and formerly by colloquial usage the eldest son of any family was called a dauphin.

DAUPHIN, a S. E. co. of Penn., bounded W. and S. W. by the Susquehanna river, and drained by many small streams; area, 530 sq. m.; pop. in 1850, 35,754. The Kittatinny or Blue mountain crosses the middle of the county, and several parallel ridges extend on each side of it, while South mountain runs along the S. border. Between these ranges there are fertile valleys, those of the S. being of limestone formation and especially fruitful. The N. part is rich in anthracite coal, and iron ore is also found. The productions in 1850 were 340,755 bushels of Indian corn, 308,879 of wheat, 370,027 of oats, 115,827 of potatoes, 27 814 tons of hay,

and 575,668 lbs. of butter. There were 37 grist mills, 19 saw mills, 2 coal mines, 4 iron furnaces, 2 foundries, 2 forges, 1 rolling mill, 1 powder mill, 8 manufactories of agricultural implements, 5 woollen factories, 15 tanneries, 7 newspaper offices, 84 churches, and 6,223 pupils attending public schools. The Susquehanna canal passes along the W. border, and the county is crossed by the Union canal, and by the east Pennsylvania, Cumberland valley, and northern central railroads. Organized in 1785, and named in honor of the dauphin of France. Capital, Harrisburg.

DAUPHINÉ, an ancient province in the S. E. part of France, bounded N. and W. by the Rhone, E. by the Alps, S. by Provence. Its surface is highly varied and picturesque, intersected by branches from the Alps. Dauphiné became one of the provinces of France in 1349, when the eldest son of the king assumed the title of dauphin. The people proved faithful to their new prince, but maintained their provincial rights and privileges with unfailing firmness. This spirit of independence broke out on the eve of the revolution, and the provincial estates of Dauphiné were the first to urge on the royal government the necessity of summoning the states-general of the kingdom. The province now forms the departments of the Isère and Hautes-Alpes, and part of the Drôme, with an aggregate population of 1,000,000. Grenoble was its capital.

DAVENANT, Sir William, an English dramatist, born at Oxford in 1605, died April 17, 1668. Shakespeare on his journeys from London to Stratford was in the habit of stopping at the tavern kept by his father at Oxford; and there is a scandalous story that he was the natural son of the great dramatist, which does not seem, however, to rest on any good authority. But this much is certain, that a striking resemblance existed between him and Shakespeare, and that the latter took considerable notice of the youth, who, at the age of 10 years, penned a sonnet "in remembrance of Master William Shakespeare." Leaving college without completing the usual academic course, he became page to the duchess of Richmond, and afterward to Lord Brooke, who, himself a man of letters, took pleasure in encouraging his page's poetic talents. About 1628 he began to be known by his masques, which were played at court by the nobility of both sexes. In 1638, on the death of Ben Jonson, he was appointed poet laureate. During the civil wars he remained faithful to the royal cause, for which the king knighted him, and also made him a lieutenant-general of artillery. He was once arrested as a royalist, but effected his escape to France. While at the court of the queen-mother Henrietta he conceived the project of leading a colony of French artisans to Virginia. The ship, however, was captured by a parliamentary cruiser, and he was carried prisoner to England. After 2 years' imprisonment he was released, on the intercession, it is said, of the poet Milton. Being without means of support, and plays being now out of fashion, he composed a number of entertainments of a moral cast, which proved successful. At the restoration he obtained the privilege of forming a new company of comedians, and being in favor with the reigning powers, was enabled to show his gratitude to Milton by interesting himself in his behalf. He contributed much, as manager of the court theatre in the reign of Charles II., to improve theatrical performances. He introduced movable scenery, richer costumes, and closer attention to the accessories generally. His works consist of fugitive pieces of versification, dramas, of which the best is the "Siege of Rhodes," masques, and an unfinished epic somewhat ponderous in style, entitled "Gondibert."—Charles, an English political writer, eldest son of the preceding, born in 1656, died Nov. 14, 1714. He was graduated as doctor of civil law at Oxford, and was a member of parliament in 1685, 1698, and 1700. In 1685 he was appointed inspector of plays, in conjunction with the master of the revels, and from 1703 to the time of his death he officiated as inspector-general of exports and imports. In his youth he composed a tragedy, called "Circe," in which he himself acted. A selection of his political and commercial works was published by Sir Charles Whitworth (London, 5 vols. 8vo.).

DAVENPORT, a city and the capital of Scott co., Iowa, on the right bank of the Mississippi, just below the upper rapids, opposite Rock Island, Illinois, and 55 m. E. from Iowa City; pop. in 1840, 600; in 1850, 1,848; in 1856, 11,500; in March, 1858, 16,677. Of the last number 50 per cent. were Americans, 20 per cent. Germans, and 12 per cent. Irish. In the township outside of the city there were beside about 1,500 inhabitants. The city is built at the foot of a bluff rising gradually from the river, and enclosed on the land side by an amphitheatre of regular hills half a mile in the rear. The back country is a rich farming region. The city presents the aspect of a prosperous commercial and manufacturing mart. It has direct communication with Chicago by the Chicago and Rock Island railroad, which terminates at Rock Island, and with Iowa City by the Mississippi and Missouri railroad, finished as far as the state capital, and designed to extend to the W. border of the state. A magnificent railroad bridge across the Mississippi connects the 2 cities of Davenport and Rock Island. It is 1,582 feet long, has 5 arches, and rises 21 feet above high-water mark. On the Iowa side there is a draw for steamboats, but the work has been much complained of, as an obstruction to navigation, particularly by citizens of St. Louis, and a legal decision has lately been rendered against the bridge. It was commenced in 1854 and finished in 1856. Davenport is regularly laid out, and beside the county buildings, contains many imposing edifices. It is the seat of Iowa col-

lege, opened in 1848, and now occupying a handsome limestone building, 3 stories high, erected on an eminence in 1855 at a cost of $22,000. It ha a library of 1,800 volumes, and numbers about 100 students, of whom ⅓ are young ladies. The other educational establishments include the Mount Ida female college, a commercial college, 7 public schools, with an aggregate average attendance of 988 pupils, and numerous private seminaries. There are 17 religious societies, viz.: 3 Presbyterian, 1 Congregational, 2 Episcopal, 2 Methodist, 1 Lutheran, 2 Baptist, 3 Roman Catholic, 1 Disciples', 1 Free Thinkers' association, and 1 German congregation. One monthly, 4 weekly, 1 tri-weekly, and 2 daily newspapers are published, and the city contains 1 book publishing house, 8 banking houses, 15 hotels, 5 flour mills, 5 saw and planing mills, 3 breweries, 7 brick yards, 5 iron works, 3 marble works, 9 manufactories of coaches and wagons, 1 of locomotives and railroad cars, 4 of agricultural implements, 4 of soap and candles, and 1 of piano fortes, 1 tannery, gas works, &c. The statistics of the chief branches of trade for the year ending Dec. 31, 1857, show an aggregate of business amounting to $14,485,812 24. The imports amounted to 53,099 tons, and the exports to 34,157 tons, most of which were transported by railroad. The receipts of lumber were 22,213,216 feet, about ⅔ of which came by river, and the principal receipts by railroad were as follows: shingles, 3,370,000; railroad iron, 1,593 tons; coal, 13,095; oats, 33,843 bushels; Indian corn, 75,834; wheat, 183,297; pork, 362,285 lbs.; machinery, 183,436. Exports by river and railroad: wheat, 94,008 bushels; barley, 20,667; flour, 106,319 bbls.; coal, 5,647 tons; lumber, 16,048,112 feet; shingles, 5,890,000. The first settlement at Davenport was made in 1836, the site having been purchased the year before by a company for $2,000. It was organized as a town in 1839, and as a city in 1851.

DAVENPORT, John, 1st minister of New Haven, Conn., born in Coventry, England, in 1598, died in Boston, Mass., March 15, 1670. He was educated at Oxford, and became an eminent preacher among the Puritans in London, and minister of St. Stephen's church. About 1630 he was engaged in the project of purchasing the church lands in England in the hands of laymen, for the benefit of poor congregations, and great progress was already made in the execution of the plan when it was interrupted by Bishop Laud, who was apprehensive that it would turn to the profit of the nonconformists. Soon becoming one himself, Mr. Davenport was obliged to resign his pastoral charge, and retired to Holland in 1633. There he became engaged in a controversy, taking sides against the general baptism of children, as was then practised, and in about 2 years returned to London. Seeing a letter from Mr. Cotton, containing a favorable account of the Massachusetts colony, he went to Boston, where he arrived June 26, 1637. There he took part in the synod held soon after, and on March 30, 1638, sailed with a company for Quinnipiac, or New Haven, to found a new colony. The first Sabbath after their arrival, April 15, he preached under an oak. He was minister there for 30 years, and aided in establishing the system of civil polity, which began by the declaration that "all of them would be ordered by the rules which the Scriptures held forth to them." On June 4, 1649, holding their constituent assembly in a barn, the "free planters" resolved that church members only should be burgesses, and Davenport was chosen one of the "seven pillars" to support the ordinance of civil government. He exhorted the governor to judge justly, and the "cause that is too hard for you to bring it to me." Annual elections were ordained, and God's word established as the only rule in public affairs. In his carefulness in regard to the admission of members to the church, he held in reality also the keys of all political power. Such was his reputation abroad, that he was invited with Hooker and Cotton, by the assembly of divines at Westminster, to take a seat among them. When the messengers of the king, who had come to New England in pursuit of Goffe and Whalley, the regicide judges of Charles I., approached New Haven, he hid the fugitives in his house, and preached to his congregation from Isaiah xvi. 3 and 4: "Hide the outcasts: bewray not him that wandereth. Let mine outcasts dwell with thee, Moab: be thou a covert to them from the face of the spoiler." After the death of Wilson, the pastor in Boston, in 1667, he was called and removed there to succeed him.

DAVEZAC. See Avezac.

DAVID, the 2d king of Israel, was the youngest of the 7 sons of Jesse of Bethlehem in Judah, and was still tending the flocks of his father when he was chosen by the prophet Samuel as the future king of his nation. He was even then remarkable for beauty, valor, and skill as a player on musical instruments. Having been brought to the court of Saul to soothe the melancholy of the king by his harp, and distinguished himself by challenging and slaying the Philistine giant Goliath, he won the friendship of Saul's son Jonathan, and the love of his daughter Michal, as well as the admiration of the people; but he at the same time drew upon himself the jealousy, and finally the fury of the unhappy king, who repeatedly attempted to kill him, though he gave him his daughter in marriage. Saved by the devotion of his wife and her brother, and protected by the favor of Samuel and the priests, David escaped to Philistia, and afterward collected a band of outlaws and malcontents in the southern part of Judah, at whose head he baffled every attempt of Saul to capture him, and even twice found opportunities of taking revenge on his pursuer, but on each occasion dismissed him without injury. Living mostly on booty from the hostile neighbors of the Hebrews, he continued a roving life till the death of Saul and Jonathan in the battle of Mount Gilboa (1055 B. C.), when he was acknowledged as king by his native tribe, and

made Hebron his residence, while Abner, the general of Saul, proclaimed Ishbosheth, the son of the latter, as the legal successor to the throne. The rivalry of the 2 houses lasted for 7 years, and ended, after the assassination of Abner by Joab, the general of David, with that of Ishbosheth by 2 obscure persons. David, now king of the whole nation, conquered the citadel of Zion from the Jebusites, made Jerusalem his capital and the seat of the national worship, which he organized with the aid of priests, prophets, poets, and musicians, entered into friendly relations with Phœnicia, and defeated the Philistines, the Moabites, the Syrians, the Edomites, and the Ammonites, thus making the limits of his country to extend from the Euphrates to the Mediterranean, and from Damascus to the Arabian gulf. The military power of the state attained its highest pitch during his reign, and a corresponding development of prosperity, culture, and literature was at least prepared. But the prophet Nathan prohibited him from building the temple, which he intended, because of the blood he had shed in war. The later years of his life were embittered by the consequences of polygamic disorder in his house, and the passions and ambition of some of his sons, by revolts, conspiracies, and a dreadful pestilence. His son Absalom, having taken a bloody revenge on his half brother Amnon for the rape of his sister Tamar, and lived for some years in exile, was reconciled with his father, but afterward conspired against him and brought about an almost general insurrection, which, but for his own blunders and the devotion and courage of a part of the army, would have proved fatal to David. Absalom fell by the hands of Joab; Sheba, a Benjamite, who immediately after him raised the standard of rebellion, was subdued by Amasa, the successor to Joab in command; a conspiracy of Adonijah, another of David's sons, was baffled by the speedy proclamation of Solomon, son of Bath-sheba, as heir and king. Shortly afterward the aged monarch died (1015). His graceful elegy on Saul and Jonathan is one of the most admirable of his poems, but it is principally the "Psalms," that have immortalized his name. (See Psalms.)

DAVID, Félicien, a French composer, born at Cadenet, in Vaucluse, March 8, 1810. His earliest instruction in music was acquired at Aix, where he sang in the choir of the cathedral, and whence at the age of 20 he went to Paris, and entered the conservatory. Soon after he joined the St. Simonians, for whom he composed the music of the choruses sung at their establishment at Ménilmontant, and with some of whom, on the dissolution of the sect, he travelled in Egypt and the East. The fruits of his travels were seen in the *Désert*, a choral symphony, published in 1844, several years after his return to Paris. On this piece, which aims at giving impressions of the physical aspects of the East, and which abounds in melodic and harmonic beauties, his reputation mainly rests. He has written a number of operas, of which the *Perle du Brésil*, produced in 1851, has proved the most successful, and has recently finished a 5 act opera, entitled *La fin du monde*.

DAVID. I. Jacques Louis, a French painter, born in Paris, Aug. 31, 1748, died in Brussels, Dec. 29, 1825. His taste for painting was fostered by his uncle Buron, the architect, and further developed in the studio of the historical painter Vien, the same who subsequently presided over the French academy at Rome. David, having succeeded in 1775 in obtaining the great prize for one of his paintings, followed his master to Rome, and there imbibed that love for classical art which afterward caused him to be hailed in France as the great reformer who had wrought the same change in painting which Corneille had introduced into the drama. His first important work, the "Plague of St. Roch," was executed by him at Rome for the lazaretto of Marseilles. This was followed, after his return to Paris in 1780, by "Belisarius" and "Andromache lamenting the Death of Hector." In 1784 he returned to Rome, and there finished his great picture of the "Horatii," which was greeted with enthusiasm in Italy and France. In 1787 he produced the "Death of Socrates;" in 1788, the "Loves of Paris and Helen;" and in 1789, his famous "Brutus," which had been ordered by Louis XVI. as a pendant to the "Horatii." In 1793 we find him in the convention as one of the representatives of the city of Paris, and voting for the death of the same monarch who had previously been his patron. But although actively engaged in politics, he was far from neglecting his art, and beside the "Oath of the Tennis Court," and the "Entry of Louis XVI. into the Assembly," executed in 1790 for the constituent assembly, he found in the tragical incidents of the reign of terror abundant elements for the exercise of his genius, as evidenced by his pictures of the assassination of Le Pelletier and of Marat. At the same time he became the great oracle on all public occasions in reference to the arrangement of festivals and the costumes of civil and military officers—a task peculiarly congenial to him, and at the same time enhancing his popularity with the people of Paris, who delighted in mimicking the manners of the republicans of antiquity. The same Grecian and Roman predilection which he brought to bear upon his paintings swayed his mind in these arrangements, and also appeared in his occasional political speeches. After the downfall of his favorite hero Robespierre, he was put in prison, released after 4 months, through the intercession of his pupils, but soon after rearrested and detained until the promulgation of the amnesty of Oct. 24, 1795. While in prison, he commenced his celebrated picture of the "Sabines," which he finished in 1799. He was engaged upon a picture of Leonidas at Thermopylæ, when his services were put in requisition by Napoleon, for whom he executed a series of works during the consulate and empire, of which the "Coronation" and the "Dis-

tribution of Eagles" pleased the emperor best; while the picture in which Bonaparte is represented upon an impetuous horse, on Mount St. Bernard, pointing out to his soldiers the path to glory, which is now in the Berlin museum, was the most popular. Expelled from France soon after Napoleon's downfall, he betook himself to Brussels, but not without having before his departure from Paris given another proof of his patriotism by refusing to execute the portrait of the duke of Wellington. In his exile at Brussels he produced "Cupid and Psyche," the "Farewell of Telemachus and Eucharis," the "Wrath of Achilles," and "Mars disarmed by Venus," which were exhibited all over Belgium for charitable purposes; while a copy of his "Coronation of Napoleon," also executed by him at Brussels, made a successful tour through Great Britain and the United States. In his later pictures we find the classical rigidity of his previous works softened to some extent by a greater infusion of sentiment. He excelled also in portrait painting, his heads of Marat and Pius VII. constituting his most remarkable achievements in this branch of art. Girodet, Gros, Gérard, Drouais, Ingres, Isabey, David d'Angers, and many others who have become eminent artists, were among his pupils, and became the disciples of the new school which he inaugurated. His body was buried at St. Gudule, in Brussels, and his heart in Père la Chaise, where his family have erected a monument to his memory. II. Pierre Jean, a French sculptor, commonly called David d'Angers, after the town of Angers, where he was born, March 12, 1789, died in Paris, Jan. 4, 1856. He was not a relative of the famous painter of his name, although he was his pupil and married his niece. When only 20 years old he obtained a medal of encouragement from the academy of fine arts, and in 1811 his bass-relief of Epaminondas, which is in the museum of his native town, gained the first prize for sculpture, and along with it a pension to finish his education in Italy, his struggles with poverty having previously been relieved by an annual allowance of $50 from his townsmen of Angers, and by his celebrated namesake, who gave him gratuitous instruction. He passed 5 years at Rome; then visited London, where, although in indigence, he rejected an advantageous offer to execute a monument commemorative of Waterloo; and on his return to Paris established his reputation by his statue of Condé, which is at Versailles, and by one in marble of King René of Anjou, for the town of Aix. He was elected a member of the academy of fine arts, Aug. 5, 1826, and appointed professor, Dec. 6, 1826. In 1828 he went to Weimar, where he modelled a bust of Goethe in marble, and presented it to that town; he also executed it in bronze for the city of Munich. In 1834 he revisited Germany, executing at the latter city a bust of Schelling, at Dresden one of Tieck, and at Berlin one of Rauch and one of Humboldt. From 1835 to 1837 he was employed upon his sculptures of the Pantheon, now the church of St. Geneviève, at Paris, which constituted the great work of his life. His other productions embrace bass-reliefs for the palace of Fontainebleau; "Christ," the "Virgin," and "St. John," for the cathedral of Angers; "St. Cecilia singing the Praise of God," for the church of St. Maurice of Angers; "A Shepherd Beholding Himself in the Water," for the museum of the same place; the "Battle of Fleurus," and the "Battle of Heliopolis," for the triumphal arch at Marseilles, beside a great number of kindred works of art. He also executed medals, busts, and statues of celebrities of all countries, including Washington and Lafayette, in the house of representatives at Washington; Jefferson and Fenimore Cooper, in New York; Berzelius in Copenhagen; Bentham in England; Lady Sydney Morgan in Ireland; Gutenberg at Strasbourg; Corneille at Rouen; Racine at La Ferté-Milon; Cuvier at Montbéliard, and at the *jardin des plantes* in Paris; Talma, Mlle. Mars, and Joseph Chénier, at the *théâtre Français* in Paris; Henry II. at Boulogne; Francis I., Louis XVI., Bernardin de St. Pierre, and Casimir Delavigne, at Havre; Fénelon at Cambray; Châteaubriand, Lamartine, Walter Scott, Canning, Victor Hugo, Béranger, Hahnemann, Arago, Lamennais, Madame de Staël, André Chénier, Rossini, Paganini, in Paris; Börne, General Foy, St. Cyr, Suchet, Gobert, and many other monuments, at Père la Chaise. The mausoleum of Marco Bozzaris at Missolonghi, presented by him as a token of his sympathy with the Grecian struggles for national independence, is one of his best productions. His last work, the statue of Dr. Bichat, was placed in the great court of the medical school of Paris on July 16, 1857. In politics he was an ardent republican. He was a representative of the people of his native department of Maine-et-Loire in the constituent assembly of 1848, invariably voting and exerting his influence and pen in favor of the republican party. After the *coup d'état* of Dec. 2, 1851, his name, which was endeared to the people and in the same proportion obnoxious to Louis Napoleon, appeared in one of the earliest lists of the proscribed. He took refuge at Brussels, and was not permitted to return to France until after nearly 3 years of exile, during which time he visited Greece. David excelled more by his immense capacity for labor than by originality and greatness of genius, many of his productions aiming rather at effect than at fidelity to nature. The universal regard in which his name is held by the best minds of France was evident at his funeral at Père la Chaise on Jan. 8, 1856, when an extraordinary crowd of eminent men attended, headed by the veteran poet Béranger, while Cavaignac was one of the pall bearers, both of whom have since followed him to the grave.

DAVIDSON. I. A W. central co. of N. C.; area, 630 sq. m.; pop. in 1850, 15,320, of whom 2,992 were slaves. The Yadkin river washes its western border, and several smaller streams

intersect it. The surface is diversified by hills and valleys, and nearly all of the land is fertile. Gold has been found in the southern part of the county. The productions in 1850 were 82,424 bushels of wheat, 507,961 of corn, 174,085 of oats, and 932½ bales of cotton. There were 5 saw mills, 4 tanneries, and 41 churches. Formed from Rowan county in 1822, and named in honor of Gen. William Davidson. II. A N. central co. of Tenn., divided into 2 nearly equal parts by the Cumberland river; area, 750 sq. m.; pop. in 1850, 38,881, of whom 14,175 were slaves. The surface is slightly uneven; the soil is good and well watered, and agriculture is in a forward state. The limestone found here is of excellent quality. In 1850 the productions were 1,598,463 bushels of corn, 162,315 of oats, 108,351 of sweet potatoes, 261,304 lbs. of butter, 38,322 of wool, and 1,277 bales of cotton. There were 61 churches, and 1,493 pupils attending public and other schools. The Cumberland river in this part of its course is navigable for steamboats, and 8 good turnpike roads, leading to different parts of the state, meet in this county. Nashville, the capital of the state, is the seat of justice.

DAVIDSON COLLEGE, a post village of Mecklenburg co., N. C., and the seat of Davidson college, an institution founded in 1840, and having about 100 students, and a library of 5,000 or 6,000 volumes.

DAVIDSON, Lucretia Maria, an American poetess, born at Plattsburg, N. Y., Sept. 27, 1808, died Aug. 27, 1825. She wrote verses at 4 years of age, having taught herself in secrecy to copy the letters from printed books. The earliest of her productions which are preserved were written when she was 9 years old. When she was 16 she was placed, through the care of a friend, at a young lady's school in Troy, where her application soon undermined her health. She was still allowed to continue her studies, even when weakened by medical treatment, and even to increase her labor to prepare for a public examination, the result of which was a hectic consumption from which she died. Although a great part of her compositions were destroyed, 278 pieces remain, some of which were published in 1829, with a memoir by Mr. S. F. B. Morse, afterward republished with a life by Miss Sedgwick. The volume produced a remarkable sensation, and was noticed by Southey in the "Quarterly Review" with the observation: "In our own language, except in the cases of Chatterton and Kirke White, we can call to mind no instance of so early, so ardent, and so fatal a pursuit of intellectual advancement."—Her sister, Margaret Miller, born March 26, 1823, died Nov. 25, 1837, had the same sensibility and precocity, and began to write at 6 years of age. At 10 she wrote and acted in a passionate drama in society at New York; and notwithstanding the warning of her sister's fate, her intellectual activity seems to have been tolerated rather than restrained. But both of them possessed such influence, through characters of almost angelic loveliness, as to make it impossible to deny them the pleasure which they enjoyed and conferred by their compositions. Margaret's poems were introduced to the world under the auspices of Washington Irving, and the works of both sisters were published together in 1850.

DAVIDSON, William, an American general in the war of the revolution, born in Lancaster co., Penn., in 1746, fell in the battle of Cowan's ford, N. C., Feb. 1, 1781. His parents removed to Rowan co., N. C., when he was 4 years old, and he was educated at the Queen's museum, afterward styled Liberty Hall academy, at Charlotte. He took up arms at the outbreak of the revolution, was major of one of the first regiments raised in Carolina, was appointed brigadier after the battle of Camden, and in 1781 was despatched by Greene to prevent Cornwallis from passing the Catawba at Cowan's ford. With his death in the battle which ensued, and with the dispersion of his troops, began the pursuit of Greene by Cornwallis.

DAVIE, a W. central co. of N. C.; area, about 250 sq. m.; pop. in 1850, 7,866, of whom 2,171 were slaves. It has a rough, hilly surface. Yadkin river and Hunting creek are the principal streams. In 1850 the productions were 29,076 bushels of wheat, 301,010 of corn, and 79,029 of oats. The county was organized in 1836, and named in honor of Gen. William R. Davie. Capital, Mocksville.

DAVIE, William Richardson, an American revolutionary officer, born in England, June 21, 1756, died at Camden, S. C., Nov. 8, 1820. He was brought to North Carolina when he was 6 years old, and was graduated at Princeton, N. J., in 1776. He returned to North Carolina, and began to study the law, but soon entered the revolutionary army, and obtained a captaincy in Pulaski's legion. At the time of Gates's defeat he expended the last shilling of an estate bequeathed him by his uncle, William Richardson, in equipping the company which he commanded. He rose to be colonel and commissary, served throughout the war, and was a favorite officer under Sumter and Greene. At the peace he returned to his profession, and was a member of the convention to form the U. S. constitution in 1787, and advocated its acceptance in the convention of North Carolina. Through his influence the university of North Carolina was established. He was elected governor of that state in 1799, and soon after appointed by President Adams envoy to France, being joined with Chief Justice Ellsworth and Mr. Murray. After his return he lived in South Carolina.

DAVIES, Charles, LL.D., an American mathematician, born at Washington, Litchfield co., Conn., Jan. 22, 1798. While yet a lad he emigrated with his father to St. Lawrence co., N. Y., and settled on the shores of Black lake, then little else than a wilderness. Here he pursued the usual occupations of a farmer till he was sent to the military academy at West Point, which he entered as a cadet in 1814. From that in-

stitution he was graduated with the rank of lieutenant in the light artillery. After a brief but active service with his regiment, he was transferred to the corps of engineers, and assigned to duty at the academy to assist as teacher in a course of instruction through which he had but recently passed as a pupil. In 1816 he relinquished the line of army promotion for that of the academy, and after filling in succession the offices of assistant professor of mathematics and natural philosophy, succeeded to the charge of the mathematical department, and was commissioned professor in 1823. In addition to the arduous duties incident to his new position, he undertook the preparation of a series of text books upon his favorite study. In this he sought to give to his pupils, by a connected course of mathematical training, the free and ready use of their mental powers, rather than a collection of detached propositions, which, however valuable as elements of knowledge, are too often wanting in logical connection as a means of education. While engaged in the execution of this project, his health gave way. A bronchial affection suspended for a while his labors, forced him to resign his post at West Point, and in 1837 to visit Europe. The change had, as was supposed, the desired effect, and soon after his return he accepted the professorship of mathematics in Trinity college, Hartford, Conn., and resumed his labors as teacher and author. But the disease of the throat again threatened, and he relinquished this position for that of paymaster in the army, and treasurer of West Point academy. These posts he resigned in 1845, and, believing his health firmly restored, resumed his favorite occupation of the lecture room and the desk in the university of New York, where he took the direction of the departments of mathematics and natural philosophy. Shortly afterward he retired to the country to seek in rural pursuits the health and repose essential to the realization of his educational plans, and at his residence near Fishkill Landing, on the Hudson, completed his series of text books. Not long after he resumed his professional duties, first in the normal school at Albany, and afterward in Columbia college, of which latter institution he now directs the mathematical studies. His works, which are numerous, are characterized by great perspicuity and clear logical arrangement, and, considered as a series, present a natural order of sequence which makes them a valuable contribution to the educational resources of the country. They consist of a "Primary Arithmetic and Table Book;" "First Lessons in Arithmetic;" "Intellectual Arithmetic;" "New School Arithmetic," with key; "University Arithmetic," with key; "Grammar of Arithmetic;" "Elementary Algebra," with key; "Elementary Geometry and Trigonometry;" "Practical Mathematics;" "University Algebra," with key; "Bourdon's Algebra," with key; "Legendre's Geometry;" "Elements of Surveying;" "Analytical Geometry;" "Differential and Integral Calculus;" "Descriptive Geometry;" "Shades, Shadows, and Perspective;" "Logic of Mathematics;" and a "Mathematical Dictionary."

DAVIES, Sir John, an English poet, born in Tisbury, Wiltshire, in 1570, died in 1626. He studied at Oxford and at the Middle Temple, from which he was expelled for his unruly temper, and during his exclusion wrote most of his poems. In the reign of James I. he was attorney-general and speaker of the commons in Ireland; sat in the English parliament, and at the time of his death had just been made lord chief justice. His principal work was a didactic poem entitled *Nosce Teipsum*, or the "Soul of Man, and the Immortality thereof" (London, 1599), which, though showing no passion and little fancy, is remarkable for its condensation of thought and felicitous precision of style.

DAVIES, Samuel, D.D., an American divine, president of the college of New Jersey, born in New Castle co., Del., Nov. 3, 1724, died at Princeton, N. J., Feb. 4, 1761. He received a careful religious education at home, studied the classics, sciences, and also theology, at Mr. Blair's school at Fogg's Manor, and was licensed to preach in 1746. Ordained in the next year, he was at his request appointed to officiate at different places of worship in Hanover co., Va., where, the Episcopal church being then the established church of Virginia, dissenters were obnoxious to the civil authorities. His labors were highly successful, and led to a controversy between him and the king's attorney-general as to whether the act of toleration which had been passed in England for the relief of Protestant dissenters extended also to Virginia. The ultimate decision of the question was in the affirmative. In 1753 Mr. Davies was sent with Gilbert Tennent to England to solicit funds for the college of New Jersey, was received with favor as a preacher in England and Scotland, and was successful in the object of his mission. He resumed his pastoral labors on his return, amid the excitement of the French and Indian war, and after the defeat of Braddock preached a sermon, which was published, in a note to which occurs the passage: "... . that heroic youth, Col. Washington, whom I cannot but hope Providence has hitherto preserved in so signal a manner for some important service to his country." The first presbytery in Virginia was established through his exertions in 1755; and in 1758 he was chosen to succeed Jonathan Edwards as president of the college of New Jersey. This appointment he declined, but it was renewed the next year, when in accordance with the judgment of the synod he accepted it. A collection of his sermons was published after his death, in 3 vols., and passed through several editions in Great Britain and in America.

DAVIESS, the name of 3 counties in the United States. I. A N. W. co. of Ky., bordering on Ind.; area, about 400 sq. m.; pop. in 1850, 12,361, of whom 2,889 were slaves. The Ohio river bounds it on the N., and Green river,

a navigable stream, touches it on the W. The surface is level and the soil generally good. Coal has been found in large quantities. The productions in 1850 were 739,860 bushels of corn, 21,953 of wheat, 81,301 of oats, 3,426,633 lbs. of tobacco, 20,319 of wool, and 14,217 of flax. The county was organized in 1815, and since 1850 has been divided to form McLean county. Named in honor of Col. Joseph H. Daviess, who fell at the battle of Tippecanoe. Capital, Owenborough. II. A S. W. co. of Ind., area 423 sq. m., between the E. and W. forks of White river, which unite at its S. W. angle; pop. in 1850, 10,352. The greater part of the land is level or rolling, and fertile. There are large beds of bituminous coal in the county. In 1850 the productions were 643,685 bushels of corn, 30,200 of wheat, 59,944 of oats, and 3,938 tons of hay. There were 17 churches, and 1,124 pupils attending public schools. Organized in 1817. Capital, Washington. III. A N. W. co. of Mo., intersected by Grand river; area, 576 sq. m.; pop. in 1856, 7,970, of whom 401 were slaves. The surface is moderately uneven and most of the soil fertile. Cattle and swine are raised in considerable numbers. In 1850 the county produced 212,536 bushels of corn, 19,168 of wheat, 45,936 of oats, and 742 tons of hay. It contained 2 churches, and there were 300 pupils in the public schools. Capital, Gallatin.

DAVILA, Enrico Cattarino, an Italian historian, born near Padua, Oct. 30, 1576, murdered near Verona in July, 1631. He is the author of the celebrated "History of the French Civil Wars during the Reigns of Francis II., Charles IX., Henry III., and Henry IV." This work is perspicuous and trustworthy, and has been accepted as a standard authority and translated into several languages. Protestant writers have objected to the favorable view taken in this work of Catharine de' Medici. In this opinion Catholics either do not agree, or find excuse in the circumstance that Queen Catharine was the patron of his family and himself. The work is divided into 15 books, containing a record of the events from the death of Henry II. in 1559, till the peace of Vervins, 1598. Davila was the youngest son of Antonio Davila, whose ancestors, for 100 years, had been constables of Cyprus, from which position the elder Davila was driven impoverished, when the island was taken by the Turks. Having sought refuge at the court of France, Catharine de' Medici, as well as her husband King Henry II., took him into favor. He thereon sent for his young son Arrigo, whom he named Enrico Cattarino, in honor of the king and queen, and devoted him to their service. The boy commenced life as the king's page; at 18 entered the army, and distinguished himself at the sieges of Honfleurs and Amiens. Having retired from the French service and returned to Italy, he devoted himself to study, and became a member of the society of the Innominati. A duel with a poet who lampooned him, and whom he run through the body, caused him to flee to Venice. That republic was then raising troops for one of its frequent wars. Davila offered to enlist 300 men, which he did, and with them joined several expeditions; continuing to rise in the service, until he held commands successively in Friuli, Candia, Dalmatia, and elsewhere. The dedicatory epistle of his history is dated from Brescia, where he was governor. For these services he received a pension, as well as restoration to his hereditary rank of constable of Cyprus. The circumstances of his death were curious. Being appointed governor of Crema, he stopped with his family and attendants at the hamlet of S. Michele, near Verona, to demand a relay of horses. This was refused by the postmaster, who, on being reproved for his insulting conduct, shot Davila dead with an arquebuse. His companions then fell upon the party, killed the chaplain, and wounded several others. Davila's son, Antonio, killed the postmaster on the spot, and his accomplices were all hanged. Lord Bolingbroke calls Davila's history a noble writing, in many respects equal to that of Livy. It was first published by Baglioni, the printer (Venice, 1630). The best editions are those issued from the royal press (Paris, folio, 1644), and by Apostolo Zeno in 2 vols. folio (Venice, 1733), the latter with a biography of Davila.

DAVIS. I. A S. E. co. of Iowa, bordering on Mo.; area, about 480 sq. m.; pop. in 1856, 11,528. Fox river flows through it, and it is drained by the sources of Wyaconda and Fabius rivers. It has an undulating surface and a rich soil, but timber is scarce. In 1856 the productions were 1,056,735 bushels of Indian corn, 95,212 of wheat, 273,226 of oats, 28,236 of potatoes, 13,738 lbs. of butter, and 3,215 tons of hay. The county was named in honor of Garrett Davis, former member of congress from Kentucky. Capital, Bloomfield. II. A N. co. of Utah; area, more than 1,000 sq. m.; pop. in 1850, 1,134. It lies on the E. shore of Great Salt Lake, and is traversed by the Wahsatch mountains. Productions in 1850, 17,675 bushels of wheat and 16,033 lbs. of butter. Capital, Farmington.

DAVIS, Andrew Jackson, an American clairvoyant, born at Blooming Grove, Orange co., N. Y., Aug. 11, 1826. While yet very young, he was taken into the employment of a neighboring farmer, and up to his 12th year spent most of his time in leading cattle to and from the pasture, and watching them in the fields. In Sept. 1838, he removed, with his father's family, to Poughkeepsie, where, up to the year 1843, he was employed mostly as a shoemaker's apprentice. Early in 1843, Mr. William Levingston of Poughkeepsie succeeded, by mesmeric passes, in throwing him into a state of magnetic somnambulism, and developing in him surprising phenomena of clairvoyance. Owing to the extreme poverty of his parents, he had been left in a state of almost entire ignorance, the whole term of his school tuition not exceeding some 5 or 6 months; and

in his normal state he displayed no great degree of natural talent. The magnetic passes, however (as is asserted by the numerous persons who were intimate with him at this time), seemed to transform him into a totally different being, and enabled him to discourse on medical, psychological, and general scientific subjects, employing their technical terms and phrases with the facility of a learned professor. Soon after this, he associated himself with Mr. Levingston, his magnetizer, and commenced the treatment of the diseased, giving diagnoses and prescriptions while in the magnetic trance. In this he was regarded as eminently successful, and by the mental phenomena which he exhibited while in this state, many were attracted to him as to an oracle of superior wisdom. On March 7, 1844, without the assistance of the mesmeric passes, he fell, into a singular trance, during which, while mysteriously hiding himself from his friends for 16 hours, he held converse, as he asserts, with invisible beings, and received intimations and instructions concerning the position he was subsequently to occupy as a teacher from the interior state. In the summer of 1845 he left his first magnetizer, Mr. Levingston, and associated himself with Dr. S. S. Lyon, then of Bridgeport, Conn., but who soon, by direction received from him while in the trance, removed with him to New York. There, in Nov. following, he induced the Rev. William Fishbough (then of New Haven) to join him as an amanuensis, and commenced the dictation, in the clairvoyant trance, of his first and most considerable work, entitled "The Principles of Nature, her Divine Revelations, and a Voice to Mankind." The matter composing this octavo of nearly 800 pages was dictated in 157 essays. These, as declared by the amanuensis and numerous witnesses, were written word for word as they were enunciated, and subsequently printed in strict fidelity to the ideas and technical terms, the very phraseology being preserved as far as possible, though much grammatical revision was found to be necessary. The book embraces a wide range of subjects, ontological, cosmical, theological, spiritual, and social, which are presented in the aspect of a unitary system, the pervading *animus* of which is a kind of attenuated and semi-spiritual naturalism, which ignores and repudiates any special divinity or sacredness attaching to the teachings of the Bible. After the completion of this book, Mr. Davis ceased to submit himself to magnetic manipulations, but has written several other works, while more or less illuminated, as he claims, by the influence of invisible spirits. These works are severally entitled the "Great Harmonia," 4 vols.; the "Approaching Crisis," the "Penetralia," the "Present Age" and "Inner Life," the "Magic Staff" (his autobiography); beside which he has published a few minor productions. The philosophical and theological portions of these works are regarded by Mr. Davis's friends as little more than repetition of his first work, interspersed with startling asseverations concerning things in heaven and earth that admit of no direct verification. As a writer, Mr. Davis has been more successful than as a public lecturer, though in this latter capacity he has had some influence; and to his general instrumentality that modern movement known as "spiritualism" partly owes its inauguration.

DAVIS, Charles Henry, an American mathematician, born in Boston, Mass., Jan. 16, 1807, the son of the late Hon. Daniel Davis, for many years the solicitor-general for Massachusetts. He entered the U. S. navy in 1823, and received in 1854 the commission of commander, which he now holds. From 1844 to 1849 he was an assistant in the U. S. coast survey, under the superintendence of Prof. A. D. Bache. In the years 1846–'49, he was engaged in a careful survey of the waters about Nantucket, in the course of which he discovered the "new south shoal," and several smaller shoals, directly in the track of ships sailing between New York and Europe, and of coasting vessels from Boston. These important discoveries were thought to account for several wrecks and accidents before unexplained, and they called forth the special acknowledgments of insurance companies and merchants. When Commander Davis left the survey, for the purpose of taking charge of the "American Ephemeris and Nautical Almanac," Prof. Bache addressed a letter to the secretary of the treasury, lamenting his loss and complimenting him in very high terms ("Coast Survey Report," 1849, p. 72). During and since his connection with the coast survey, Commander Davis has been appointed on several commissions to examine the state of the harbors of Boston, New York, Charleston, &c. These investigations led him to the study of the laws of tidal action. See his important "Memoir upon the Geological Action of the Tidal and other Currents of the Ocean" ("Memoirs of the American Academy," new series, vol. iv.), and the "Law of Deposit of the Flood Tide" ("Smithsonian Contributions," vol. iii., art. 6). The "American Nautical Almanac" owes its foundation directly to Commander Davis's patriotic efforts, which were begun and sustained in spite of a very general scepticism with regard to its success. He was appointed the first superintendent of the work in 1849, and the organization devised for it by him at the very beginning is the same, in every important particular, as that under which it still continues to be executed. He continued at the head of this establishment till the autumn of 1856, when he was ordered to naval service in the Pacific, as commander of the sloop of war St. Mary's, and from this post he has not yet (Jan. 1859) returned. Commander Davis is the author of an English translation of Gauss's *Theoria Motus Corporum Cœlestium* (Boston, 1858), and of some shorter translations and articles in the departments of mathematical astronomy and geodesy.

DAVIS, Edwin Hamilton, an American physician and archæologist, born in Ross co.,

Ohio, Jan. 22, 1811. He was educated in the Scioto valley, so renowned for the number and magnitude of its ancient earthworks. Residing in the same county, and cognizant of the labors of Atwater and other pioneer explorers in this department of science, his attention was directed at a very early age to the subject of American antiquities. From 1829 to 1833, while a student of Kenyon college, he conducted a series of explorations in the mounds of that vicinity, an account of which was given in a paper read before the philomathesian society, afterward (by request of the professors) enlarged, and delivered as a literary performance at the commencement of 1833. In 1833 he had several interviews with the late Daniel Webster, then making a tour of the West. This great statesman, who was deeply interested in western antiquities, was pained to witness their rapid disappearance, and suggested the formation of a society to purchase and preserve some of the most remarkable works of the mound-builders. The opinion of such a man was well calculated to stimulate the youthful mind of Dr. Davis to continue these researches. For 15 years he diligently studied the subject, and the results of his researches are embodied in the "Monuments of the Mississippi Valley," which forms vol. i. of the "Smithsonian Contributions to Knowledge." Dr. Davis received his medical degree at Cincinnati in 1837, after which he settled and practised his profession in Chillicothe until 1850, when, on the establishment of the New York medical college, he was called to fill the chair of materia medica and therapeutics, which he still holds. He has been an occasional contributor to some of the scientific and medical journals, beside being for a time one of the conductors of the "American Medical Monthly." During the spring of 1854 he delivered a course of lectures on archæology before the Lowell institute in Boston.

DAVIS, Henry, an American divine and scholar, born at East Hampton, N. Y., Sept. 15, 1770, died at Clinton, March 7, 1852. He was graduated at Yale college in 1796, then became tutor successively at Williams and at Yale colleges, and in 1806 professor of Greek at Union college. In 1809 he was chosen to the presidency of Middlebury college, Vt., and in 1817 accepted that of Hamilton college, N. Y., having in the year preceding declined the same situation at Yale college, offered him on the death of President Dwight. He continued at the head of Hamilton college until 1833, and was meanwhile active in the establishment of the theological seminary at Auburn, and the American board of commissioners for foreign missions. He possessed considerable merit as an orator, and was the author of various occasional sermons. In 1829 and 1830 no students were graduated at the college because of a long and bitter dispute between the president and trustees upon a case of discipline. After his resignation in 1833 he published a "Narrative of the Embarrassments and Decline of Hamilton College."

DAVIS, Jefferson, an American soldier and statesman, born June 3, 1808, in that part of Christian co., Ky., which now forms Todd co. Soon after his birth his father, Samuel Davis, a planter, who served during the revolutionary war in the mounted force of Georgia, removed with his family to Mississippi, and settled near Woodville, Wilkinson co. Young Davis received an academical education, and was sent at the usual age to Transylvania college, Ky., which he left in 1824 to enter the U. S. military academy at West Point, where he was graduated in 1828, and was appointed brevet 2d lieutenant. He remained in the army 7 years, and served as an infantry and staff officer on the N. W. frontier in the Black Hawk war of 1831–'32, with such distinction that, March 4, 1833, he was promoted to a 1st lieutenancy of dragoons, in which capacity he was employed in 1834 in various expeditions against the Comanches, Pawnees, and other hostile Indian tribes. He resigned his commission, June 30, 1835, returned to Mississippi, and became a cotton planter, living in retirement till 1843, when he began to take an active part in politics on the democratic side, and in 1844 was chosen one of the presidential electors of Mississippi to vote for Polk and Dallas. In Nov. 1845, he was elected a representative in congress, and took his seat in December of that year. He bore a conspicuous part in the discussions of the session on the tariff, on the Oregon question, on military affairs, and particularly on the preparations for war against Mexico and on the organization of volunteer militia when called into the service of the United States. While in congress, in July, 1846, the 1st regiment of Mississippi volunteers, then enrolled for service in Mexico, elected him their colonel. He promptly left his seat in the house, and overtaking his regiment at New Orleans on its way to the seat of war, led it to reënforce the army of Gen. Taylor on the Rio Grande. He was actively engaged in the attack and storming of Monterey, Sept. 1846; was one of the commissioners for arranging the terms of the capitulation of that city; and highly distinguished himself in the battle of Buena Vista, Feb. 23, 1847, where his regiment, attacked by an immensely superior force, maintained their ground for a long time unsupported, while Col. Davis himself, though severely wounded, remained in the saddle until the close of the action, and was complimented for his coolness and gallantry by the commander-in-chief in his despatch of March 6, 1847. At the expiration of the term of its enlistment, in July, 1847, the Mississippi regiment was ordered home; and Col. Davis while on his return received at New Orleans a commission from President Polk as brigadier-general of volunteers, which he declined accepting on the ground that the constitution reserves to the states respectively the appointment of the officers of the militia, and that consequently their appointment by the federal executive is a violation of the rights of the states. In Aug. 1847, he was appointed by the

governor of Mississippi U. S. senator to fill a vacancy, and at the ensuing session of the state legislature, Jan. 11, 1848, was unanimously elected to the same office for the residue of the term, which expired March 4, 1851. In 1850 he was reëlected for the ensuing full term. In the senate he was chosen chairman of the committee on military affairs, and took a prominent part in the debates on the slavery question, in defence of the institutions and policy of the slave states, and was a zealous advocate of the doctrine of state rights. In Sept. 1851, he was nominated candidate for governor of Mississippi by the democratic party, in opposition to Henry S. Foote, the candidate of the union party. He resigned his seat in the senate on accepting the nomination, and was beaten in the election by a majority of 999 votes; a marked indication of his personal popularity in his own state, for at the "convention election" 2 months before, the union party had a majority of 7,500. After his defeat Col. Davis remained in retirement until the presidential contest of 1852, when he took the stump in behalf of Gen. Pierce in Mississippi, Tennessee, and Louisiana, where he rendered essential service to the democratic party. In 1853 he was appointed by President Pierce secretary of war, which post he held till the accession of President Buchanan in 1857. His administration of the war department was marked by ability and energy, and was highly popular with the army. He proposed or carried into effect, among other measures, the revision of the army regulations; the introduction of camels into America; the introduction of the light infantry or rifle system of tactics; the manufacture of rifled muskets and pistols and the use of the Minié ball; the addition of 4 regiments to the army; the augmentation of the seacoast and frontier defences of the country; and the system of explorations in the western part of the continent for geographical purposes, and for the determination of the best route for a railroad to the Pacific ocean. Having been previously reelected, on his retirement from the war department Col. Davis reëntered the senate for the term ending March 4, 1863. In the sessions of the 35th congress he has been conspicuous in the discussions on the French spoliation bill, which he opposed, and on the Pacific railroad for the southern route, of which he is a zealous and most influential advocate.

DAVIS, John, an English navigator, born at Sandridge, in Devonshire, died in 1605. He was early inured to a sea-faring life, and distinguished himself by 3 voyages between 1585 and 1587 for the discovery of the north-west passage. He discovered in 1585 the strait which bears his name, and in the following year navigated along the coast of Greenland as far northward as lat. 72°. In 1591 he went as second in command with Cavendish in his unfortunate voyage to the South sea. He afterward made 5 voyages to the East Indies, and was killed in the strait of Malacca by Japanese pirates. He invented a quadrant which was in use for taking the sun's altitude at sea till it was superseded by Hadley's sextant, and published accounts of two of his voyages, and curious works entitled the "World's Hydrographical Description" (1595), and the "Seaman's Secrets" (1595).

DAVIS, John, LL.D., an American jurist, born at Plymouth, Mass., Jan. 25, 1761, died in Boston, Jan. 14, 1847. He was graduated at Harvard college in 1781 with reputation, especially as a poet and mathematician; engaged for a time as teacher in the family of Gen. Joseph Otis of Barnstable, a brother of the revolutionary orator; completed his legal studies in Boston, and began the practice of law in Plymouth in 1786. His first public office was as delegate to the state convention on the question of adopting the federal constitution. He was the youngest of the members of that convention, and lived to be the last survivor. For several years he was representative in the state legislature, was elected senator from Plymouth county in 1795, and in that year was appointed by Washington comptroller of the treasury of the United States. Resigning this office after one year, he soon received the appointment of United States attorney for the district of Massachusetts, and removed to Boston. In 1801 President Adams appointed him judge of the district court, and he fulfilled the duties of this office for more than 40 years. Judge Story thus bears witness to his judicial ability in dedicating to him one of his works: "Your judgments have stood the test of time, and are destined to be laid up among the *responsa prudentium* for professional instruction in future ages." Throughout his official career, from which he retired in 1841, he continued his studies in the classics, sciences, and poetry; and his character is revealed in his favorite quotation from Malebranche: "Truth loves gentleness and peace." Especially interested in the history and antiquities of New England, he was a member of the historical society of Massachusetts from the year of its organization (1791), and its president from 1818 to 1843. Among his publications are a "Eulogy on George Washington;" an "Attempt to Explain the Inscription on Dighton Rock," in which he ingeniously supposes the figures designed to commemorate exploits of Indian hunting; and an edition of "Morton's New England Memorial," to which he added copious marginal notes, and an appendix replete with curious information.

DAVIS, John, an American statesman, born at Northborough, Mass., Jan. 13, 1787, died at Worcester, April 19, 1854. His father was a New England farmer, in moderate circumstances. His early days were spent on his father's farm. He was graduated at Yale college in 1812, and was admitted to the bar of Worcester co. in 1815. In March, 1822, he married Eliza, the eldest daughter of the Rev. Dr. Bancroft of Worcester. In 1824, on no other nomination than the newspaper suggestion of an unknown friend, he was elected a member of congress, and continued to hold that office by successive reëlections until Jan. 1834,

when, having been elected governor of Massachusetts, he resigned his seat. In March, 1835, having been elected to the U. S. senate, he resigned the office of governor, but reassumed it in 1841, and continued to discharge its duties till Jan. 1843. In March, 1845, he was again elected to the U. S. senate, and remained there until March, 1853, when he declined a reëlection, and retired to private life. In the early part of his professional career Mr. Davis was identified with the federal party; but, beyond writing occasionally for the local journals, had little to do with politics. His practice was extensive. His reputation as a man of sound learning, of practical sagacity, and of sterling integrity, made him essential to one or the other litigant in every important cause in his county. This left him little leisure for public affairs. His first entrance on public life was on the floor of congress. Coming from a quarter of the country already interested in manufactures, and from a district noted for the mechanical skill and industry of its population, he naturally became an advocate for protection to American industry. The tariff of 1824 had not given satisfaction to the manufacturing interests, and the people from all parts of the northern and middle states were petitioning congress to interpose legislative aid to protect the wool growers and manufacturers. Mr. Davis was a protectionist in advance of public opinion in New England. He thought that government should so lay the import duties which were necessary for revenue, that the industry of the country should be expanded, and its labor made more productive and more profitable. He advocated these views on the floor of congress with zeal and power. The speeches delivered by him in the sessions of 1828, 1830, and 1832, in reply to Mr. McDuffie, Mr. Cambreleng, and others, were regarded by the protectionists as the best statements and defences of their theories. During his first term in the senate, that body was mainly occupied with the controversy with Gen. Jackson's administration, of which he was a consistent opponent. He took a prominent part in the opposition to the expunging resolutions, and, it is understood, drafted a part, if not the whole, of the famous protest against them. He also acted with the whig party in opposing the administration of Mr. Van Buren, and contributed, in a short speech against the sub-treasury in 1840, the most efficient electioneering pamphlet for the canvass of that year. It was computed that more than one million copies of this speech were circulated among the voters. Before this time, the long public service and incorruptible integrity of Mr. Davis had gained for him the popular appellation of "Honest John Davis," a title which clung to him through life. During his second term as governor, the so-called Dorr rebellion took place in Rhode Island. He was urged by each side to render it aid, but refused to abandon the neutrality which he said Massachusetts ought to observe. For this, and for an imprudent act of one of his military staff, he failed of a reëlection by the people, and the legislature after a protracted struggle supplanted him by a democrat. During his absence from the senate, the protective tariff of 1842 had gone into operation, and upon his return he found a democratic administration about to substitute for it the revenue scale of 1846. In the discussion of this measure he resumed in the senate the place in the protectionist ranks which he had formerly held in the house. Mr. Davis opposed the Mexican war from the beginning. He was one of the two senators who voted that the war did not exist by the act of the republic of Mexico. He supported the treaty of Guadalupe Hidalgo in opposition to his colleague and other whig senators. In the great controversy which followed, as to the disposition to be made of the territories of the United States, he was decided and earnest in favor of excluding slavery from them. He supported what is known as the Wilmot proviso during the administration of Mr. Polk, and he was one of the most decided opponents of what were known as the compromise acts during the administration of Gen. Taylor and Mr. Fillmore. He had no fear of a dissolution of the union. He retired from public life just as the passage of the compromise acts had completed the dissolution of the whig party, with which he had acted during his whole career. For a brief period, surrounded by friends whom he loved and respected, his favorite agricultural pursuits afforded occupation for his leisure hours. But his constitution was undermined, and a short but painful illness soon terminated his life.

DAVIS, John A. G., professor of law in the university of Virginia, born in that state in 1801, died Nov. 14, 1840. He was educated at William and Mary college, and commenced the practice of law in the county of Albemarle. He was also for a time editor of a journal published at Charlottesville. In 1830 he was appointed to the law professorship in the university, and performed its duties with great promise and success. He was for some time chairman of the faculty. Hearing one night the report of a pistol before his door, he went out to ascertain the cause, and found there a student masked, who slowly retreated before him, and deliberately discharged a pistol at him. He died in consequence. He published a volume on criminal law for the use of justices of the peace, the copyright of which was purchased by the legislature from his family for $12,000.

DAVIS, Matthew L., an American writer, born in 1766, died at Manhattanville, N. Y., June 21, 1850. He was originally a printer by trade, and acquired in the course of that business a desultory education and considerable skill as a writer. He early attached himself in politics to the fortunes of Aaron Burr, and was an advocate of his elevation to the presidency, at the time when the balance hung so long undecided between him and Jefferson. For many years he was the correspondent at Washington of the "New York Courier and Enquirer," under the signature of "The Spy in Washington." For the "London

Times" also he wrote under the name of the "Genevese Traveller." During many years before the death of Aaron Burr Mr. Davis was apparently his only attached friend, and the most important of his writings is his "Memoirs of the Life of Aaron Burr." Burr's diary was also edited by him.

DAVIS'S STRAIT, an arm of the North Atlantic ocean, communicating with Baffin's bay, and separating Greenland on the east from Cumberland island on the west. It stretches north from Cape Farewell, about lat. 60° N., to Disco island, near lat. 70° N. Its narrowest part, where it is cut by the arctic circle, is 220 miles wide; its greatest breadth is about 600 miles. Its coasts are high, rocky, broken by numerous bays and inlets, the largest of which are Northumberland inlet and Hudson's strait, almost barren, and peopled by tribes of Esquimaux. Notwithstanding its dangerous currents and vast icebergs, it is a favorite resort for whalers, the whale being found here in greater number than in any other polar waters.

DAVITS, the projecting arms of wood or iron upon which boats are hoisted and hung over the sides or stern of ships. They are rigged with sheaves or blocks for that purpose.

DAVOUST (or more correctly DAVOUT), LOUIS NICOLAS, a French general, born at Annoux, in Burgundy, May 10, 1770, died in Paris, June 1, 1823. A schoolmate of Bonaparte at the military school of Brienne, he was, when only 15, appointed 2d lieutenant in a cavalry regiment. In 1791 he served as major in the army commanded by Dumouriez, and was a brigadier-general as early as 1793, while Bonaparte was but a major. In that capacity he was employed for 3 years in the armies on the Moselle and the Rhine, where he gained the esteem of Moreau, who intrusted him with important commands. He accompanied Bonaparte to Egypt, and greatly contributed to the victory at Aboukir. On his return to France he was appointed division-general in 1800, chief commander of the consular guard in 1801, and in 1804 marshal of the empire. He took a distinguished part in the victories of Ulm and Austerlitz; and on the same day that Napoleon conquered the Prussians at Jena (Oct. 14, 1806), he won over them the victory of Auerstadt, and received as a reward the title of duke of Auerstadt. In 1809 he was made prince of Eckmühl, for his part in the battle of that name. After Wagram he was appointed military commander in Poland, which country he ruled with an iron hand. In the Russian campaign he defeated Bagration at Mohilev, and was wounded at the battle of the Moskwa (Borodino). After the disastrous retreat from Russia, he took up his head-quarters at Hamburg, where he was soon besieged by the victorious allied armies. He boldly opposed their forces; and it was only in April, 1814, that he consented to deliver the city into the hands of Gen. Gérard, a commissioner of Louis XVIII. Napoleon, on his return from Elba, appointed him minister of war. After the defeat at Waterloo, he was placed in command of all the troops in and around the capital, and was ready for the contest when he received positive orders from the provisional government to negotiate with the allies. In consequence of this order, he signed, July 3, 1815, at St. Cloud, the capitulation of Paris. A few days later he consented to a mere acknowledgment of the new government, and retired from active life. On the trial of Marshal Ney, he boldly declared that he would not have signed the capitulation of Paris if it had not, in his opinion, guaranteed the safety of all the military men then in that city. The firmness of his conduct was not palatable to the Bourbons; he was not fully reinstated in his position until 1818.—His only son, born in 1818, was a member of the chamber of peers, and for some time connected with the army, but became afterward insane, and died Aug. 18, 1853.

DAVY, SIR HUMPHRY, an English chemist, born at Penzance, Cornwall, Dec. 17, 1778, died at Geneva, Switzerland, May 29, 1829. He was the eldest son of Robert and Grace Davy; he was a healthy, active, and forward child, fond of sports and stories, of retentive memory, and of a remarkably affectionate disposition. He made rapid progress at his first school; at the grammar school, kept by an incompetent teacher, he followed no particular course of study, but studied what and when he pleased, and during his stay there gave no indication of the great powers he exhibited in after life; he acquired, however, a good knowledge of Latin and Greek, and appears always to have stood at the head of his class. Among his boyish tastes was that of fishing, the relish for which he never lost, and which was the subject of his delightful book "Salmonia." At the age of 9 he went to live with Mr. John Tonkin, a friend of his mother, who from regard to her in a manner adopted the young Humphry, when his family removed to Varfell, about 2½ miles from Penzance. At the age of 14 he went to Dr. Cardew's school at Truro, where he remained nearly a year at the expense of his kind friend, Mr. Tonkin, to whose house in Penzance he returned in Dec. 1793; his school education was now at an end, and his self-education, to which he owed almost every thing, was about to commence. The next year was passed in desultory study, in active sports with gun and rod, and in occasional dissipation; this was a most dangerous period of his life, but he resisted the temptations which beset him, and began to study again in earnest. The death of his father in Dec. 1794, and the narrow circumstances of his family, gave fixedness to his vacillating purposes, and it was determined that he should study the art of medicine; accordingly, in Feb. 1795, he was apprenticed to Mr. Borlase, a surgeon and apothecary of Penzance, who was afterward distinguished as a physician. His studies were now followed with great zeal; his note books show that he gave attention to a great variety of subjects beside those coming within the strict line of his profession, such as the modern languages, mathematics, metaphys-

ics, and especially chemistry and physics; he grappled with some of the highest problems of metaphysical theology and mental philosophy, and at one time seemed lost in the perplexities of materialism. While cultivating the intellect his imaginative powers were not neglected, as is proved by his love of poetry and by the composition of verses of considerable merit; his chosen subjects of study were illustrated by the reading of the best works within his reach. From physics his attention was naturally turned to chemistry, which he took up with ardor toward the end of 1797, at the commencement of his 19th year, though only in reference to his medical progress; the reading of Lavoisier's "Elements of Chemistry" first led him to the experimental study of the science in which he was destined to work such remarkable changes; his apparatus was of the rudest kind, his materials such as are most commonly used in medicine, and his first experiments very simple; yet so rapid was his progress that in 4 months he had sent to Dr. Beddoes, an Oxford ex-professor of chemistry, a new theory on "Heat and Light," to which the latter became a convert; this was his first publication, which appeared in 1799. The young chemist's mental activity was favored by the acquaintance of Mr. Gregory Watt, a son of the famous James Watt, who came to reside at Penzance in the winter of 1797 for the benefit of his health; in the society, conversation, and sympathy of this young man, Davy found the stimulus he needed in the development of his intellectual powers. He also became acquainted with Mr. Davies Gilbert, a scientific and highly educated man, afterward his successor as president of the royal society of London. The mineralogical and geological structure of the surrounding country, abounding in tin and copper mines, the lithological characters of the cliffs and headlands, and the ever-changing air and sea of that tempestuous climate, invited him to the investigation of the operation of natural causes; his very first original experiments, at the age of 18, were to determine the kind of air which filled the vesicles of the common sea weeds thrown upon the shore, and he demonstrated that the marine plants act upon the air in precisely the same way as the terrestrial, by decomposing, under the influence of the sun's rays, carbonic acid, in order to obtain the carbon necessary for their growth, and the oxygen for their respiration. The state of chemical science, too, was favorable to his rapid advance, as its boundaries were small, its theories ill-defined, most of its departments little developed, and vast unexplored regions waiting for the coming of a master spirit. His medical studies must have been zealously pursued, as in their 4th year he was considered by Dr. Beddoes competent to take charge of his pneumatic institution at Clifton, in which pulmonary diseases were treated by the inhalation of different gases. Mr. Borlase kindly released him from his apprenticeship, and early in Oct. 1798, he left Penzance, before he was 20 years old, to commence his public career at Clifton, near Bristol. In the year 1799, while resident at Clifton, he made his experiments on the protoxide of nitrogen (laughing gas), and published the results in 1800; he described its effects, which were much like those since produced by the inhalation of sulphuric ether; he also experimented with carburetted hydrogen, carbonic acid, and nitrogen, thereby seriously injuring his health. About the same time he had taken up the subject of galvanism, which afterward led to some of his greatest discoveries in decomposing the alkalies and alkaline earths. The pneumatic institution soon became very popular under his management, and some of the most obstinate diseases were benefited by the new remedies; the nitrous oxide was found very beneficial in many cases of palsy. The royal institution had just been founded after a plan of Count Rumford, with the intention of diffusing a knowledge of science in its applications to the common purposes of life; Davy received and accepted the invitation to become lecturer on chemistry, and in March, 1801, he took up his abode in London, and in May, 1802, he was formally appointed professor in the institution. His lectures at once became exceedingly popular; his youth, simple manners, eloquence, his knowledge of his subject, and his brilliant experiments, excited the attention of the highest ranks in London; his society was courted by all, and he seemed in danger of becoming a votary of fashion rather than of science. During the 11½ years that he spent in the rooms of the royal institution, his bachelor apartments were furnished in the simplest manner; in the adjoining laboratory he spent most of his time, preparing for his lectures, and conducting his investigations on the fixed alkalies, on astringent vegetables in connection with the art of tanning, on the composition of mineral substances, on agricultural chemistry, on galvanism, and on electro-chemical science, which may be said to have sprung chiefly from his researches. His observations on tanning were published in the "Philosophical Transactions" for 1803; his lectures before the board of agriculture, which were delivered until 1813, were published under the title of "Elements of Agricultural Chemistry," a work which has passed through many editions, and has been translated into almost every European language. His important researches in electro-chemical science had been commenced at Clifton, and the results are published in the "Philosophical Transactions" from 1808 to 1812, and in the early "Bakerian Lectures" of 1806–'7, the base potassium having been discovered on Oct. 6, 1807, and sodium a few days after, by decomposing moistened potash and soda by several voltaic batteries; his delight was most extravagant but excusable when he saw the globules of potassium appear and take fire as they entered the air. The mental labor of his experiments and the excitement of his discoveries threw him into a typhoid condition, which threatened his life for

a period of several weeks; on his recovery he experimented with a battery of 2,000 plates, discovered the base boron, showed the simple nature of chlorine, sulphur, and phosphorus, the compound nature of ammonia, and many other important facts. In 1803 he was elected a fellow, and in 1807 one of the secretaries of the royal society, which appointment he held for 5 successive years, an honorable and acceptable office to him, as it brought him into friendly intercourse with scientific men. The medical profession, which he had laid aside on coming to London, seems now to have been resumed for a short time; but the claims of science had too great an attraction, and he gave up medicine as he had previously declined an invitation to enter the church. So great was his reputation as a lecturer that he was invited to deliver courses before the Dublin society in 1810 and 1811, for which he received about $6,000, and was made doctor of civil law by Trinity college. He was knighted in April, 1812, by the prince regent, and in the same month married Mrs. Apreece, the widow of Shuckburgh Ashby Apreece, Esq., who brought him a considerable fortune; he was afterward created baronet. In the autumn of 1813, by express permission of the French government, granted on account of his scientific reputation, he visited the continent during the war, in company with Mr. Faraday "as his assistant in experiments and in writing;" the assistant has proved the peer of his master. While in Paris, where he spent 2 months, he became acquainted with the most eminent men of science, as Cuvier, Laplace, Gay-Lussac, Humboldt, and Vauquelin; during this brief period he discovered that iodine is a simple substance, analogous in its chemical relations to chlorine. He remained on the continent until the spring of 1815, visiting the south of France, Italy, and Switzerland, devoting special attention to the volcanic regions, and pursuing his chemical researches on colors, the iodine compounds, and oxymuriate salts, which were published in the "Philosophical Transactions" for 1815. As one of the results of his journey, he states in a letter to his mother that "England is the only country to live in, however interesting it may be to see other countries." Already in the front rank of scientific men, his next discovery placed him among the greatest benefactors of his race. In 1812 a terrific explosion of gas took place in a coal mine, causing the death of more than 100 men; and after many other such disasters, a committee of proprietors of mines waited upon Davy to see if his knowledge could devise any way of preventing similar accidents in future. He began by analyzing the gas, and ascertaining in what proportions its mixture with air rendered it most explosive, and the degree of heat necessary to ignite it; from observing that the combustion did not take place through tubes of small dimensions from the refrigerating effect of the metallic mass, he gradually reduced the length of the tubes till he found that a simple fine metallic gauze was sufficient so to cool the burning gas in its passage through it as not to ignite the great explosive mass on the outside; he accordingly covered the lamps with a wire tissue, whose interstices were of the thickness proper to cool the burning gas which passed through it to a degree to prevent combustion, being permeable to air and light, but not to flame. This simple contrivance constituted the miner's safety lamp, and has saved the lives of thousands; the dangerous gas may burn within the gauze, and thus give timely warning, and may at last extinguish the lamp, but even then a suspended platina spiral will remain glowing in the midst of the explosive gas, and by its illumination enable the miner to see as long as the air is fit for respiration. His attention was first drawn to the subject in Aug. 1815, and in December his lamp was completed; urged by a friend to take out a patent for his invention, he nobly replied: "No, my good friend, I never thought of such a thing; my sole object was to serve the cause of humanity; and if I have succeeded, I am amply rewarded in the gratifying reflection of having done so." In May, 1818, he left England on a second continental journey, visiting Germany, Hungary, and Italy, and returning to England in June, 1819. On the death of Sir Joseph Banks in 1820, Sir Humphry Davy was almost unanimously elected president of the royal society of London, an office to which for 7 years afterward he was annually elected without opposition; thus the poor boy of Penzance by the strength of his own intellect had attained the highest honor to which a man of science in England can aspire, and the learned body over which he presided lost nothing of its ancient reputation during his official connection with it. The last term of his scientific labors extends from 1823 to the summer of 1826, during which time he communicated to the royal society 3 papers on the preservation of metals by electro-chemical means, and the Bakerian lecture for 1826, "On the Relation of Electrical and Chemical Changes." As in the case of the safety lamp, it was to remedy a practical evil that these papers were prepared. His attention was directed by the commissioners of the navy to the corrosion of the copper sheathing on the bottoms of vessels by the sea water; he ascertained that the popular notion that impure copper is soonest corroded is an error, and that the corrosion is owing to the joint action of the air and the saline ingredients in the water; he succeeded in preserving the copper sheathing from corrosion by rendering it negatively electrical by small pieces of tin or zinc, or iron nails, these metals making a surface of copper from 200 to 300 times their own size so electrical as to have no action on sea water; the very perfection of the protection rendered this method practically inapplicable where speed was requisite, as shells and sea weeds adhered to the non-corroded surface. This principle of galvanic protection has been successfully applied to various important uses in the arts and sciences. In 1824 he

made a journey to Norway, Sweden, Denmark, Holstein, and Hanover, admiring the scenery, fishing and hunting, and communicating with their eminent men, among whom were Berzelius, Oersted, Gauss, Olbers, and Schumacher. In 1825 he began to experience considerable indisposition, which ever after affected his ordinary elasticity of spirits, depressed also by the illness and death of his mother in 1826. He had suffered for more than a year with numbness and pain in his right arm, when toward the close of 1826 he had a paralytic attack, affecting the right side of the body; his mental faculties were not impaired, and while confined to his room he corrected the proof sheets of his "Discourses to the Royal Society," published in Jan. 1827. In this month he had so far recovered as to start on a journey to the continent, going through France, over Mt. Cenis into Italy, where he occupied himself in hunting, fishing, and observations on natural history and chemical science, for about 3 months; he then journeyed through various parts of southern Germany and Switzerland, returning in October, with health and strength slightly improved, to England, where he remained until March, 1828. "Salmonia, or Days of Fly-fishing," is a kind of dramatization of the most interesting parts of his journal in these last travels, rendered doubly valuable by his observations in natural history, and glowing with the most exalted ideas of God drawn from nature. Finding no permanent improvement in his health, he left London again in March, 1828, for the Alpine regions of southern Austria, where he passed the summer, spending the winter in Italy; during this journey he wrote the "Consolations in Travel," his last writing, which Cuvier calls the work of a dying Plato. On Feb. 20, 1829, he experienced at Rome a sudden and severe paralytic attack, which ultimately proved fatal, though he so far improved as to quit Rome on the last of April for Geneva, where he arrived May 28; he dined at 5 P.M. and retired at about 9½ o'clock; at 2½ the following morning he was taken alarmingly ill, and in a few moments expired; he was buried, in accordance with his expressed wish, where he died, in the city of Geneva, on June 1. His brother believed that the paralysis was caused by softening of the brain, which, with some enlargement of the heart, was the cause of his death. Sir Humphry Davy was of middle stature, 5 feet 7 inches in height, well proportioned and muscular, and able to endure considerable fatigue; of sanguine temperament, warm in his feelings, of cheerful disposition, fond of company, persevering and observing; he devoted himself assiduously to science, keeping aloof from political strife. He was chosen a member of the French institute in 1817; he was also connected with most of the great academies of Europe, and was by universal consent considered without a superior, if he had an equal, among the chemists of his time. His memory is dearly cherished at Geneva, where his widow founded a prize in his honor, to be given every 2 years for the most original and important discovery in chemical science. Beside the life by his brother, there is one by John Ayrton Paris, M.D. (2 vols. 8vo., London, 1831).—Davy, John, M.D., a younger brother of the preceding, and the writer of his biography. After taking his degree of doctor of medicine at the university of Edinburgh in 1804, he was attached to the English army, and travelled extensively in the East. He was the author of several works of merit, the principal of which, beside the life of his brother, in 2 vols. 8vo., are: "An Account of the Interior of Ceylon and of its Inhabitants, with Travels in that Island" (4to., London, 1821; this work is especially valuable for its details on the natural history of Ceylon); "Researches, Physiological and Anatomical" (2 vols. 8vo., London, 1839); "Notes and Observations on the Ionian Islands and Malta, with some Remarks on Constantinople and Turkey" (2 vols. 8vo., 1842). Dr. Davy has spent most of his life in the foreign army service of his country, but was the travelling companion and physician of his illustrious brother during the last period of his life. He has published many important papers in the "Philosophical Transactions," several of which are collected, with illustrations, in his "Researches, Physiological and Anatomical." In 1858 he published a volume entitled "The Fragmentary Remains of Sir Humphry Davy."

DAWES, Rufus, an American poet, born in Boston, Jan. 26, 1803. He entered Harvard college in 1820, but did not graduate on account of a charge of participating in some disturbance. The charge was afterward disproved, and furnished the occasion for his first published poem, directed against the Harvard faculty. He was admitted to the bar, but has never practised. He was a contributor to the "U. S. Literary Gazette," and conducted for a time the "Emerald," a journal printed at Baltimore. He published in 1830 the "Valley of the Nashaway and other Poems;" and in 1839, "Geraldine, Athenia of Damascus, and Miscellaneous Poems," comprising descriptions of natural scenery, songs, and odes. The next year he published "Nix's Mate," a historical romance. Mr. Dawes is a Swedenborgian, and has frequently officiated in the pulpits of that denomination.

DAWSON, George, an English clergyman and lecturer, born in London in 1821, was educated at the university of Glasgow, and became in 1844 the pastor of the Baptist Mount Zion chapel in Birmingham. His independence of character and disregard of the conventional usages of the denomination caused a separation in the congregation and a new chapel to be built for the minister, which was opened in 1847 under the name of the "church of the Saviour." He has been very successful as a lecturer, and is a proprietor of the "Birmingham Daily Press."

DAX, an arrondissement and town in the S. W. of France, department of Landes; pop. of the former in 1856, 113,794, and of the latter 6,125. The town is situated on the left bank of the Adour, about 30 m. S. W. from Mont-de-

Marsan, and is a principal station on the railway from Bordeaux to Bayonne. The most remarkable building is the cathedral, built in 1646 after the design of Vauban. It has manufactories of liquors and delft, and some trade is carried on in grain, wine, timber, vegetables, wax, and honey; and the town is a considerable entrepot of goods exported from France to Spain. It is of ancient origin, and has hot mineral springs, whence it was called by the Romans Aquæ Tarbellicæ, afterward by the French Villa d'Acqs, and then simply Dax.

DAY, the period of the earth's rotation on its axis. This is not, however, the most common meaning of the word, which cannot be exactly expressed without preliminary explanations. The motion of the earth upon its axis is supposed to be perfectly uniform. If, therefore, a star were so distant that its apparent position could not be affected by the earth's annual motion in its orbit, the successive returns of that star to the meridian would be at equal intervals; and the fixed stars are all so distant, that they may practically be used for determining these intervals, which are called sidereal days. The sidereal day is usually considered as the time between the successive passages of the vernal equinox over the meridian, but the precession of the equinoxes is so slow that a single sidereal day thus measured does not differ sensibly from a true sidereal day. This time is, however, only of use in observatories; for civil life we need the solar day, measured by the return of the sun to the meridian. The solar day is, from a variety of causes, variable in its length. That it must be nearly 4 minutes longer than a sidereal day is manifest when we consider that the sun apparently travels eastward among the stars about twice his own breadth each day, in the accomplishment of his annual journey. But this motion is due east only at the solstices, and varies more or less at other seasons from the direction of the earth's rotation. Moreover, when the sun is nearer the poles (at the solstices), an equal amount of motion will carry him through more degrees of right ascension than when he is near the equator. Yet further, his motion is apparently most rapid when we are nearest to him, slowest when we are most distant. The solar day is thus variable in length, since it differs by a variable amount from the constant sidereal day. Clocks and watches are therefore regulated to run to the average length of the solar day, and must, of course, be sometimes faster and sometimes slower than the sun. Clock time is called true time, or mean solar time; while the time which is measured by the sun is called apparent time. The difference between the time by the clock and the time by sun, that is, between the hour of mean and of apparent time, is called the equation of time. Four times a year the equation of time is reduced to nothing, and twice a year it amounts to about 16 minutes. Mean solar time might be supposed to be measured by a fictitious sun travelling uniformly in the equator, and coming to the vernal equinox at the same instant with a second fictitious sun travelling uniformly in the ecliptic and coming to the perigee (between Christmas and new year's) at the same instant with the real sun. A day usually signifies a mean solar day. A sidereal day is 23h. 56m. 4.09s. of solar time. In astronomy the solar day begins at noon, but in civil life at midnight. In all countries the astronomical hours are numbered from noon up to the following noon, from 1 to 24; but in most countries the civil day is divided from midnight to noon, and again from noon to midnight, each period into 12 hours. There is another use of the word day as opposed to night, when it designates the time during which the sun is above the horizon. In this sense of the word, the length of the day varies greatly with the latitude of the observer, and with the season of the year. On the equator, the day is always a few minutes more than 12 hours in length; but as we proceed north its length increases in summer, and decreases in winter, until we reach the arctic circle, where the longest day is more than 24 hours, the sun not setting at all for a day or two about June 20; while the longest night is nearly 24 hours, the sun barely showing himself in the southern horizon at noon, for a few days about Christmas. At the poles, the day is a little over 6 months in length, and the night nearly as long.

DAY, Jeremiah, D.D., LL.D., late president of Yale college, born in New Preston, Conn., Aug. 3, 1773; entered Yale college in 1789; on account of infirm health was not able to go on with the class to which he at first belonged; but after an absence of several years resumed his college studies, and was graduated with high honor in 1795. This was the year of Dr. Dwight's accession to the presidency of the college, on whose removal from Greenfield Mr. Day was invited to take charge of the school in that village, which had flourished so greatly under the care of the former. This invitation he accepted, and continued there for a year, when he was elected a tutor in Williams college, where he remained till he was chosen tutor in Yale college, in 1798. Having early made choice of the profession of theology, while acting as tutor he began to preach as a candidate for the ministry; but before taking charge of any parish, he was, in 1801, elected to the professorship of mathemathics and natural philosophy in Yale college. His health, however, still being feeble, he was not able to enter on its duties till 1803; but after that continued in them till 1817, when, on the death of Dr. Dwight, he was elected his successor in the presidency. In July of the same year he was formally inaugurated, and on the same day was ordained as a minister of the gospel. In 1817 he received the degree of LL.D. from Middlebury college, and in 1818 the degree of D.D. from Union college, and the latter also from Harvard college in 1831. He continued in the presidency of Yale college till 1846, when, on account of feeble health, he resigned; and though that venerable institution

has been deemed peculiarly fortunate in its presidents, it may with truth be said that it has at no time been more prosperous than under the presidency of Dr. Day. His learning and talent, united to great kindness of heart, soundness of judgment, and urbanity of manner, secured alike the respect and love of his thousands of pupils, all of whom looked upon him more as a father and friend than as a mere teacher and guide in the ways of knowledge. Dr. Day has always been distinguished as a mathematician, and as a close and vigorous thinker on all subjects to which he turned his attention. His well-known "Algebra," first published in 1814, has passed through numerous editions; and a new and much improved and extended edition of it was issued in 1852, by the joint labors of himself and Prof. Stanley. His work on the "Mensuration of Superficies and Solids" was published in 1814, his "Plane Trigonometry" in 1815, and his "Navigation and Surveying" in 1817. These works, like his "Algebra," have gone through numerous editions, and are adopted extensively as standard works in the colleges and seminaries of the land. In 1838 Dr. Day published an "Inquiry on the Self-Determining Power of the Will, or Contingent Volition," and a second edition of the same in 1849. In 1841 he published an "Examination of President Edwards's Inquiry as to the Freedom of the Will." He has also published a number of occasional sermons, and contributed papers to the "Journal of Science," the "New Englander," &c. He still lives in New Haven, in the possession of all his faculties, and the enjoyment of a ripe old age, respected and esteemed by the entire community, as well as by thousands in every part of the land whom he has aided in training for respectability and usefulness.

DAY, John, an English printer, born at Dunwich, in Suffolk, in 1522, died July 23, 1584. He improved the Greek types then in use, was the first who printed in Saxon characters in England, and was 4 times elected warden of the stationers' company, and in 1580 master of the same. In 1544 he carried on printing in London, a little above Holborn conduit, in partnership with William Seres. In 1549 he removed to Aldersgate street, near St. Anne's church. Beside this printing office, he kept several shops where his books were sold. In 1562 he printed the first edition of John Fox's "Acts and Monuments," with cuts representing the execution of Huss, Cobham, Tyndal, Lambert, and other martyrs. Of this work no perfect copy is known to exist. His publications materially aided the reformation.—Of his 13 children, John, born in 1566, died in 1627, at Thurlow, in Suffolk, became a popular preacher; and Richard, who officiated for some time as minister at Ryegate, in Surrey, translated into English the *De Christo Triumphante Comœdia* of Fox, and followed afterward his father's business as printer, which for many years he carried on in the same place.

DAY, Mahlon, a publisher of New York, born in Morristown, N. J., Aug. 27, 1790, lost on board the steamer Arctic, Sept. 20, 1854. He was a member of the society of Friends, commenced his career in New York as a journeyman printer, but soon accumulated from his savings enough to embark in business on his own account, in which he took up a department previously neglected, that of the publication of story books and toy books for children. He also commenced and published as long as he continued in business "Day's Bank Note List and Counterfeit Detector." This was the first periodical of the kind issued, and in the multiplication of banks became important and indeed necessary to the business community. The profits of this enterprise enabled Mr. Day to retire from business, and the last 15 years of his life were spent in charitable and public-spirited labors. He was a manager of the house of refuge, of the public school society, of the institution for the blind, and of other similar institutions.

DAY, Stephen, the first printer in New England, born in England in 1611, died in Cambridge, Mass., Dec. 22, 1668. He came to this country in 1638, and commenced printing at Cambridge, by direction of the magistrates and elders, in 1639. The first thing printed was the "Freeman's Oath," in 1639; next in the same year an almanac, made by Wm. Pierce, mariner; then the Psalms, "newly turned into metre," in 1640. He also printed a catechism; "Body of Liberties," 100 laws, in 1641; and a second edition of the Psalms, 1647. From his extant works we are able to say that he was not a skilful printer. The printing house was taken from him about 1648, and put into the hands of Samuel Green.

DAY, Thomas, an English author and politician, born in London in 1748, died Sept. 28, 1789. His father, a collector of the customs, died when Thomas was a year old, leaving him an ample fortune. He was educated at the charterhouse, and at Corpus Christi college, Oxford, which he left after 3 years' study, without taking a degree. He at once began his romantic and benevolent course of life, residing successively in different parts of the continent, making himself familiar with the mental and physical wants of the lower classes of society, and alleviating them to the extent of his power. The distresses which he witnessed caused him temporary melancholy and lasting indignation against certain criminal noblemen, one of whom he vainly challenged to single combat. With peculiar views of education, he selected from the foundling hospital at Shrewsbury 2 girls 12 years of age, designing to educate them after the principles of Rousseau, and ultimately to marry one of them. His expectations, however, were not realized, and he gave portions to his *protégées* on their marriage with persons of their choice. In 1778 he married a lady of Yorkshire, having opinions and a fortune like his own, and retired to his estates in Essex and Surrey, where he took an active part in public meetings as an ad-

vocate of American independence and parliamentary reform. He published several poems and pamphlets against slavery and the slave trade, and on other political questions. The work to which he owes his celebrity is the "History of Sandford and Merton" (3 vols., 1783–'89), one of the most popular of the books designed for the information of youth, written with freshness and vigor, and inculcating the virtues and disinterested philanthropy which characterized its author. It was followed by a shorter work of fiction, entitled the "History of Little Jack." Day met his death by a kick from a young horse, which he was training on a new principle; and his wife was so afflicted by the intelligence that she never again left her darkened chamber, though she survived him 2 years.

DAYS OF GRACE, in commerce, a certain number of days after the time specified by a note or bill of exchange, allowed for the payment of the note or bill. Though formerly gratuitously granted, they may now, in accordance with custom sanctioned by the courts, be demanded. The days of grace in Great Britain and the United States are 3, but their number is larger in most continental European countries.

DAYTON, a city and the capital of Montgomery co., Ohio, at the confluence of Mad and Great Miami rivers, 66 m. W. S. W. from Columbus; pop. in 1840, 6,067; in 1850, 10,976; in 1853, 16,562. It is a place of great industrial activity, and one of the most important of the interior cities of the United States. It is regularly laid out on the E. bank of the Great Miami, with streets 100 feet wide, crossing each other at right angles, lighted with gas, and lined with tasteful private residences, surrounded by fine gardens. The public buildings display a magnificence rarely equalled in commercial cities of such rapid growth. The county court house, planned after the model of the Parthenon, is an imposing edifice, 127 feet long by 62 feet wide, of coarse but compact white marble, quarried in the neighborhood. The roof is of stone, the doors are of solid iron, and the cost of the whole was somewhat over $100,000. There are 2 market houses, one of which, 400 feet long, and paved with blocks of limestone, has accommodations for a city hall and council chamber in the second story. The churches are 17 in number, viz.: 1 Albright's, 2 Baptist, 1 Dunkers', 1 Disciples', 2, Episcopal, 1 German Reformed, 2 Lutheran, 2 Methodist, 1 New Light, 2 Presbyterian, and 2 Roman Catholic. The last named church has an orphan asylum and 2 female academies, one conducted by sisters of charity, and the other by sisters of Notre Dame. There are 5 public common schools, 1 high school, several private seminaries, a large seminary called the Cooper female academy, a prosperous library association and lyceum, and a mechanics' benevolent society. The newspaper press comprises 4 daily and 6 weekly publications. There are 2 private banking houses, a chartered bank with a capital of $100,000, and a branch of the state bank of Ohio. There is an immense water power within the city limits, a great part of which is obtained from a hydraulic canal, built by a company in 1845, and drawing its supply from a point on the Mad river 4 m. above Dayton. The power thus obtained is leased to manufacturers, and the surplus ultimately finds its way to the Miami. A further increase of water power by means of a canal from the Miami has been projected. The city contains 2 flour mills, 4 saw mills, 2 paper mills, 3 cotton factories, 2 woollen factories, 3 iron founderies, 5 machine shops, 6 large breweries, 4 manufactories of agricultural implements, the value of whose products in 1858 was $385,000, 5 oil mills, using annually 180,000 barrels of flaxseed, and manufactories of railroad cars, gun-barrels, pegs and lasts, hollow ware, &c. The car factories are on a large scale; the paper mills supply a considerable part of the West; the value of iron cast is about $500,000 per annum; and the amount of superfine flour manufactured is about 125,000 barrels a year. The assessed value of property in 1853 was $5,309,928. The Miami canal, opened in 1829, connects Dayton with Lake Erie, and the following railroads give it intercourse with all parts of the Union: the Mad river and Lake Erie, 154 m. long, terminating at Sandusky; the Cincinnati, Hamilton, and Dayton, 60 m. long; the Dayton and Western, 108 m. long, and terminating at Indianapolis; the Dayton and Michigan, 72 m. long, completed as far as Lima; the Dayton and Cincinnati short line; the Dayton, Xenia, and Belpre, to Xenia; and the Greenville and Miami, 47 m. long, to Union. Dayton was laid out in 1799, and incorporated as a town in 1805, but until the opening of the Miami canal it made little progress. It was chartered as a city in 1841. It is divided into 6 wards, and is governed by a single board of 12 councillors.

DAYTON, a post village of Marengo co., Ala., 76 m. S. W. from Tuscaloosa. It is a pleasant and prosperous place, situated in a healthy country, near a fertile cotton-growing region called the "Canebrake." It is inhabited in part by wealthy planters, whose estates lie in the vicinity, and is better known as a quiet retreat, with good society, and some facilities for education, than as a manufacturing or commercial village.

DAYTON, Elias, an officer in the American revolution, born at Elizabethtown, N. J., in 1737, died there in 1807. He commenced his military career in 1760, when he joined the British forces which were employed in completing the conquest of Canada from the French; and he subsequently commanded a company of militia, with which he marched on an expedition against the northern Indians. It is probable that this corps was a portion of the original "Jersey blues." At the commencement of hostilities between the mother country and the colonies, he was appointed a member of the committee of safety for Elizabethtown; and in 1776 he was commissioned as colonel of one of the Jersey regiments, in which

capacity he served till 1783, when he was promoted to the command of the Jersey brigade. In June, 1776, soon after the battle of Bunker hill, he signalized himself by the capture of a British transport off the coast of New Jersey, which surrendered to an expedition of armed boats under his command in conjunction with Lord Stirling. He was in active service during the whole war, and took part in the battles of Springfield, Monmouth, Brandywine, Germantown, and Yorktown. He had 3 horses shot under him, one at Springfield, one at Germantown, and one at Crosswick's Bridge. After the war he served several terms in the legislature of his native state. During the life of Washington he was on terms of intimacy with that illustrious man, by whom he was treated with distinguished confidence. Upon the formation of the New Jersey society of the Cincinnati, Gen. Dayton was chosen its president, and held that office until his death.

DAYTON, Jonathan, LL.D., an American statesman, born at Elizabethtown, N. J., Oct. 16, 1760, died there, Oct. 9, 1824. At the age of 16 he was graduated at the college of New Jersey, and 2 years afterward, in 1778, he entered the army as a paymaster. He held several commissions at different periods of the war, and after the peace of 1783 he was elected to the legislature of his native state, and was chosen speaker of the house in 1790. In June, 1787, he was appointed one of the delegates from New Jersey to the convention at Philadelphia for the purpose of framing the federal constitution. In 1791 he was elected by the federal party a representative in congress, in which capacity he served for 3 successive terms, during the last 2 of which he was speaker of the house. In 1799 he was elected to the U. S. senate. When there were apprehensions of a war with France, President Adams sent him a commission as brigadier-general, which was at first declined; but upon being informed that its acceptance would not vacate his seat in the senate, he consented to retain it. He afterward served several terms in the council, as the superior branch of the New Jersey legislature was formerly termed. Among other incidents of his somewhat eventful life, it may be mentioned that he was arrested for alleged complicity with Aaron Burr in his conspiracy, but no further proceedings were had in the case.

DAYTON, William Lewis, an American jurist and statesman, born at Baskingridge, N. J., Feb. 17, 1807. He is the son of Joel Dayton, a farmer, and was graduated at the college of New Jersey in Sept. 1825; commenced soon afterward the study of the law, and was admitted to the bar of his native state in May, 1830. In 1837 he was elected a member of the council, or senate, as it is now called, and was made chairman of the judiciary committee. On Feb. 28, 1838, he was chosen by the legislature as one of the associate justices of the supreme court of New Jersey, which position he resigned in Nov. 1841; and on the decease of the Hon. Samuel L. Southard, a U. S. senator, in 1842, he was appointed by the governor to fill the vacancy so caused. In March, 1845, his appointment was confirmed by the legislature, and he was also elected for a full term of 6 years. He served in the senate from July 6, 1842, to March 4, 1851. As a member of the senate he was what might be called a free-soil whig; he maintained to the fullest extent the right of congress to legislate with respect to slavery in the territories of the United States, on which subject he expressed his views in a speech on the treaty with Mexico in 1847. He was an intimate and influential adviser of President Taylor, the policy of whose administration he warmly supported. He advocated the admission of California into the Union as a free state, was in favor of the abolition of the slave trade in the District of Columbia, and voted against the fugitive slave bill. At the expiration of his term the democratic party was in the ascendency in the New Jersey legislature, and they chose Commodore Robert F. Stockton as his successor. Mr. Dayton now resumed the practice of his profession at Trenton; and in 1856 he was nominated by the republican national convention as their candidate for the vice-presidency of the United States, with Col. Fremont as the candidate for president. In March, 1857, he was appointed attorney-general of the state of New Jersey, which office he still holds.

DEACON (Gr. διακονος, minister, servant), an inferior minister of the Christian church. The apostles appointed 7 deacons (Acts vi.), whose duty it was to superintend the temporal concerns of the church, and to distribute alms from the common fund. Their functions were subsequently enlarged, and in the Roman Catholic church the deaconship is a major order, ranking next below the priesthood. The deacon assists the priest in the celebration of mass, during which he wears a vestment with slit sleeves called a dalmatica, and with permission of the bishop may preach and baptize. He must have entered his 23d year before being ordained, and is bound to celibacy. In the church of England he occupies a somewhat similar position, being allowed to exercise all priestly functions except consecrating the eucharist and pronouncing absolution. He may administer the wine at communion, and officiate as lecturer, curate, or private chaplain, but is incapable of ecclesiastical preferment. The Presbyterians and Independents give this name to officers elected by the church members to distribute the bread and wine to communicants; the German Protestants apply it to assistant ministers; and in Scotland it is the title of overseers of the poor, and presidents of incorporated companies.

DEACONESS, a name given to those females in the early church who were consecrated to the service of the sanctuary, and performed for women the offices which deacons filled for men. They had care of the sick and poor of their own sex. The order has been abolished in the Latin church since the 11th century, and in the Greek church since the 12th century.

DEAD RECKONING, in navigation, the estimation that is made of the place of a ship without any observation of the heavenly bodies. The data for the reckoning are the distance the ship has run by the log, and the course she has taken by the compass; and the result has to be rectified by due allowances for drift, leeway, &c. This reckoning should be corrected upon the first opportunity for an observation of the sun.

DEAD SEA, called by the Latin geographers *Lacus Asphaltites*, and by the Arabs *Birket* or *Bahr Loot*, sea of Lot. It is also known as the sea of Sodom, and in the Scriptures is spoken of as the Salt sea, sea of the Plain, and Eastern sea. Its position is about 25 m. to the east of Jerusalem, between the mountains of Moab on the east and those of Hebron on the west. The locality is that of the ancient vale of Siddim, which Lot selected when he parted from Abraham, and which was then an attractive region, watered by the Jordan, and containing the cities of Sodom and Gomorrah. Even at that early period the district was probably of peculiar geological character, the vale being described as "full of slime pits" (Gen. xiv. 10). The catastrophe which resulted in the destruction of these cities, and in the formation of the sea, is computed to have occurred about 1900 years before the Christian era. By earthquake, accompanying volcanic action (Gen. xix. 28), the valley appears to have sunk to a great depth, and the waters of the Jordan flowing in produced this sea, which was made intensely salt by the saline strata exposed to their action. On its southwest side is a mountain retaining the name of Sodom, or Oosdoom, containing strata of salt, out from which stands a lofty pillar of the same material, observed by Lieut. Lynch, of the U. S. navy, which is probably what travellers often describe by the name of Lot's wife. Josephus speaks of a similar pillar, perhaps the same, which he himself saw, and believed to be that into which Lot's wife was transformed. Clement of Rome and Irenæus also make mention of the same. It is about 40 feet high, standing upon an oval pedestal, the top of which is 40 or 50 feet above the water. The pillar of salt is capped by limestone. Bitumen or asphaltum, from which the sea receives one of its names, is found along the shores of the lake, and during some recent earthquakes, to which the region is still subject, it was thrown up in large quantities at the southern extremity of the sea. The hardened lumps of it are worked into rosaries at Jerusalem. From its abundance in this region it is often called Jews' pitch. Pieces of sulphur are met with upon the shores, and sulphurous exhalations are perceived arising from the ground. The banks are slippery, with a slimy mud, into which the foot sinks deep, and the tracks thus left are soon lined with incrustations of salt. A similar mud covers a considerable portion of the bottom, and when brought up in sounding, crystals of salt are found sticking to it, thus indicating a full saturation of the saline mixture. But a portion of the bottom is rough and rocky, and subject to sudden and great changes of depth. This feature, in connection with the pieces of lava occasionally found, seems to indicate a formation due to volcanic agency, such as is produced in other regions where "the smoke of the country is seen to go up as the smoke of a furnace." The water is dense and bitter with its heavy charge of salt, so that bodies float in it with much greater buoyancy than in other seas. In bathing, one experiences difficulty in keeping the feet down, and a man may float in it breast high without exertion. The southern part of the lake is shallow, giving an average depth of only 13 feet; but the northern portion, as sounded by Lieut. Lynch and others, is found to reach a maximum depth of more than 1,300 feet. The dimensions as given by him are 42 m. from north to south, and the greatest width nearly 10 m. A remarkable feature in the lake is its great depression below the level of the Mediterranean. By the levelling conducted by Lieut. Symonds of the royal engineers, which was confirmed by nearly identical results afterward obtained by the same method by Lieut. Lynch, the difference of level of the two surfaces is 1312.2 feet. This depression, which is the deepest of the kind known upon the face of the earth, extends up the valley of the Jordan toward the north to the sea of Tiberias, which is only 984 feet higher than the Dead sea. The stream of the Jordan is consequently entirely below the flow of all other rivers, and even far below the level of the sea. Yet its swift current, often rushing on in rapids dangerous to navigate, even with the iron boats of the expedition under Lieut. Lynch, pours a large volume of water into the deep basin, from which there is no outlet. During the rainy season the influx is so great from this and other streams, that the level of the sea is raised 10 or 15 feet, and its dimensions extend, especially in a southern direction, over the low flats, far beyond the ordinary margin of the waters. But in the burning heat of the dry season, when the beach becomes so hot as to blister the feet, and the water, as observed by the officers of the expedition, acquires a temperature of 90° F. a foot below the surface, the evaporation rapidly carries off the excess of water, and reduces the sea to its lowest level. The vapors are seen to rise in columns, resembling water spouts, but far exceeding them in size. At this season the air becomes so highly heated in the deep basin between the precipitous mountains which enclose it, that it is almost irrespirable, and the thermometer often rises to 106° or more, even after the setting of the sun. At midnight it was observed to be 98°. Currents of this heated air are set in motion, and sweep in hurricanes over the water. As described by the U. S. officers, the hot wind blistered the faces of the men exposed to it. Every metallic object was burning hot; the coolest substances were the inner surfaces of the clothing. If a pool of fresh water were found to bathe in, the skin was instantly afterward left dry and parched. The perspiration disappeared by evaporation as

rapidly as it was produced. In such an atmosphere, and surrounded in the intervals of the sweeping wind by swarms of mosquitoes, which tormented the men almost to madness, they cast themselves upon the pebbly beach and sought for rest, with their garments wrapped around their heads. One morning, after a night thus passed, the commander of the expedition found a young quail that had nestled by his side, seeking shelter from the hot blast of the sirocco. The hills upon each side are precipitous cliffs of limestone and sandstone in horizontal strata. On the east they are rugged mountains 2,000 to 2,500 feet high, traversed by deep chasms, desolate and bare of vegetation. On the west the height is estimated at 1,500 feet; but the summit level upon the whole is little if any higher than the surface of the Mediterranean. Much of the country between the two seas is a wilderness, without trees or shrubs, save in a few ravines fed by small water courses. In such a desolate district is the convent of Mar Saba, so near the Dead sea that the sound of its evening bell reaches the dreary solitudes of its shores, assuring the disheartened traveller that human life may be continued in this region of gloom and death. Mr. Costigan, who surveyed the sea in 1835, with a Maltese sailor as his servant, died soon after completing its tour. Lieut. Molyneux of the royal navy experienced the same fate in 1847. The excessive heat of the sun was no doubt the direct cause of their death. Two of the seamen belonging to the American expedition were sent to this convent for relief, and Lieut. Dale, the 2d officer, before the party left the country, fell a victim to the fever at Beyroot, where Lieut. Lynch also, and nearly all the men of the party, were attacked by the same disease. It is to this expedition, despatched by the U. S. government in 1847, that we are indebted for most of our exact information relative to this singular spot; though many other travellers, English, French, Russian, and American, also have been led by its ancient celebrity and mysterious nature to venture upon its exploration, and their accounts, full of interesting particulars, have been at various times presented to the public. In March, 1848, the American party, well equipped, passed across, with their boats drawn on trucks by camels, from the bay of Acre, over the mountains of Lebanon, and launched them in the lake of Gennesareth. Thence they descended the Jordan, entering the river on April 10, and passing out of its mouth into the Dead sea on the 19th of the same month. The length of the river they estimated to be at least 200 m., though in a direct course the two lakes are only about 60 m. apart. They spent 21 nights upon the shores of the Dead sea, and after having thoroughly explored the region, they left it on May 10, sending their boats across the desert to Jerusalem. Contrary to the opinion generally entertained regarding the pestilential atmosphere of this neighborhood, they found numerous animals living upon the shores of the lake, as doves, hawks, partridges, and hares, and also ducks swimming upon its surface; and a curious fact regarding the birds, insects, and other animals here met with, is that they are all of a stone color, described as "the same as the mountains and the shore." Whether animal life exists in the water itself is not so certain, though some authorities have mentioned that living shells are found in the sea, and one small species of fish is said to be peculiar to it. It is very possible that the shells may have been swept into the lake from the Jordan or other streams. The surface was in one instance at night observed to present "one wide sheet of phosphorescent foam, and the waves, as they broke upon the shore, threw a sepulchral light upon the dead bushes and fragments of rocks." This is probably owing to animalcules, such as give the same appearance to the ocean. In the sample of water brought back by the party no vestige of animal life was detected; but in Jameson's "Philosophical Journal" of Feb. 1850, it is stated that Ehrenberg found an abundance of infusoria of brackish water species in samples of the water and sediment brought to him for examination. The want of vegetable matter for food must necessarily to a great extent exclude animal life. A few plants which furnish soda in their ashes are occasionally found upon the shore, and at the foot of the cliffs is noticed a scanty vegetation of cane and of the tamarisk shrub, their foliage sometimes of a light green and sometimes of a yellow hue, stained by the exhalations of sulphuretted hydrogen; but the few bushes to be seen often present their branches leafless and incrusted with salt, and the trunks of dead trees scattered here and there add to the desolation of the scene.—Various analyses have been made by eminent chemists of the water taken from the lake, the results of which differ, in consequence, no doubt, of the different seasons of the year and portions of the lake at which the samples were taken, and also of the different methods of conducting the analyses. The specific gravity, as stated by Lavoisier, is 1.240; by Klaproth, 1.24; by Marcet, 1.211; by Gmelin, 1.212; by Apjohn, 1.153; by Salisbury, 1.1877; and by Lynch, 1.13. The constituents are thus given by different authorities:

The first of the above analyses is given in Poggendorff's *Annalen*, of a sample of the water procured from the north end of the sea, near the mouth of the Jordan.

DEAF AND DUMB, persons who can neither hear nor speak. That such have existed in all ages is evident from the not infrequent allusions to them both in sacred and profane writings. The idea of attempting the restoration of the lost faculties, or of repairing the loss by education, seems never to have occurred to the ancients. In many instances the authorities connived at, if they did not openly approve of, the destruction of such children, who it was thought could be of no benefit to the state. Among the Hindoos, in the "Ordination of the Pundits," or code of Gentoo laws, it was decreed that whoever was "deaf from his mother's womb," or whoever was dumb, should be classed among persons incapable of inheritance. But, though excluded from inheriting, they were not left without provision; for the person who superseded them in the inheritance was bound to support them—in the language of the ordinance, to allow them clothes and victuals. The code of Justinian, promulgated in the 6th century A. D., assumes throughout that deaf mutes from birth are incapable of managing their own affairs; placing them in this respect on a footing with the insane, idiots, and those suffering from permanent and incurable disease, in requiring guardianship. The same code also provides that they should only buy and sell by the aid of a curator or guardian; that they should not have the power of altering the descent of property, or of making a gift, even with the assistance of a curator. They could not make a will, or a codicil, or create a trust estate, or make a donation contingent on the death of the donor, or emancipate a slave. A singular provision of the code deserves notice. Justinian allows to those who are deaf from birth, but yet able to speak, the privileges of which deaf mutes had been deprived. Pliny, more than 400 years earlier, had said: "There is no person deaf from birth who is not also dumb." The feudal governments of western Europe, making the code of Justinian the basis of their laws, placed the deaf mute under similar disabilities. Pitiable indeed was the fate of these children of silence during the long ages of ignorance and darkness. If the advent of Christianity had prevented their murder as useless incumbrances to society, they were still left as fit companions for the idiot and the maniac. Without instruction, or any means of acquiring it, they knew nothing of the earth on which they trod or the heavens above them; if their powers of imitation enabled them to acquire some facility in the mechanic arts, this might suffice to supply the craving of the body for employment, but what should satisfy the longings of the restless spirit? Some with outstretched hands sought the alms they could not ask; others, grovelling in indolence, sank to the level of the idiots with whom alone they could associate. Yet even in the early ages of the Christian era there were not wanting those who, with infinite pains, sought to communicate instruction to the deaf mute, although the law had pronounced him incompetent to receive it. The venerable Bede relates that, in 690, John, bishop of Hagulstad, taught a deaf mute to speak, and to repeat after him words and sentences. In 1442 Rodolphus Agricola of Groningen, in his *De Inventione Dialecticæ*, speaks of having seen a deaf and dumb person who had learned to understand and practise writing. About 1550, Pedro Ponce de Leon undertook, and with considerable success, the instruction of the deaf and dumb in Spain. His labors seem to have been confined mainly to teaching reading and articulation. He relates, as instances of the successful results of his teaching, that one of his pupils received ordination as a priest, and performed his parish duties acceptably, and that another became a military officer and distinguished himself in martial exercises. In 1560 Joachim Pascha, chaplain of the elector Joachim II. of Brandenburg, instructed his own deaf-mute daughter, by means of pictures, mimic signs, and other methods of his own devising. Not far from the same time Girolimo Cardan, the eccentric Italian philosopher, detailed, in an essay which he published, the principles of deaf-mute instruction, though he never reduced them to practice. In 1620, about 36 years after the death of Ponce de Leon, Juan Paulo Bonet, a Benedictine monk of Spain, published a treatise entitled *Reduccion de las letras y artes para enseñar a hablar los mudos* ("Reduction of Letters and Arts for Teaching the Dumb to Speak"). In this treatise he represents himself as the inventor of the processes he describes, viz., mimic signs, dactylology, the oral alphabet, and writing. His work contains the first engraving of the single-hand alphabet, so generally in use throughout Christendom, and he is believed to have been its inventor. In Italy, at this time, a number of eminent philosophers were turning their attention to the subject. Affinate published an essay about the commencement of the 17th century on teaching the deaf to speak. Giovanni Bonifacio wrote a treatise on the language of action in 1616; Fabrizio di Acquapendente wrote upon the phenomena of vision, voice, and hearing, and on speech and its instruments. In 1629, Ramirez de Carion instructed the prince of Carignan, a deaf mute. Some authorities say that Ramirez himself was deaf and dumb, but had acquired sufficient education to be capable of teaching others. Some few years later, Pietro di Castro, chief physician to the duke of Mantua, instruct-

ed the son of Thomas, prince of Savoy, who was a deaf mute. Castro died in 1663. In Holland, Peter Montanus published a work on the instruction of the deaf and dumb in 1625. In 1644, John Bulwer, a philanthropic English physician, published his "Chirologia, or Natural Language of the Hand," and in 1648, "Philocophus, or the Deafe and Dumbe Man's Friend." In the latter work he refers to the account he had received from his friend Sir Kenelm Digby of Pedro Ponce's success in the instruction of the deaf and dumb. Camerarius and Gaspard Schott had, in the early part of the 17th century, published works in Germany, on the instruction of the deaf and dumb. In 1653, Dr. John Wallis, mathematical professor at Oxford, mentions, in the preface to the 5th edition of his *Grammatica Linguæ Anglicanæ*, that he had instructed two deaf mutes to articulate distinctly, adding that he had also taught them (an entirely different matter, he observes) to understand the meaning of language, and thus to use it in speaking, reading, and writing. The number of pupils under his care was never large, but he seems to have continued to instruct deaf mutes for nearly half a century; for in 1698 he was still engaged in the business, and gave a detail of the plan he was pursuing in a letter to Thomas Beverley. He deserves the credit of being the first practical instructor of the deaf and dumb in England; and in a paper published in the "Philosophical Transactions" in 1670, he distinctly enunciates the fundamental principle of De l'Épée and Sicard, that we may form conceptions in written as well as in spoken language, and states that in the work of deaf-mute instruction he proceeded from certain actions and gestures, which have a natural signification, to convey ideas not already understood. The priority of his invention was disputed by Dr. William Holder, rector of Bletchington, who asserted that he had, in the first instance, taught Popham, one of Dr. Wallis's pupils, to speak. Dr. Holder published in 1669 "Elements of Speech, with an Appendix concerning Persons Deaf and Dumb." In 1670, George Sibscota published a little work entitled the "Deaf and Dumb Man's Discourse." The work is mainly theoretical, and he, like Wallis and Bulwer, had derived most of his ideas indirectly from Pedro Ponce. The same year the Padre Lana-Terzi, a Jesuit of Brescia, published a treatise on the education of the deaf and dumb and the blind. In 1680, George Dalgarno, a Scotchman, but then the preceptor of a grammar school at Oxford, published a work called "Didascalocophus, or the Deaf and Dumb Man's Tutor," in which he expresses a preference for written language and a manual alphabet over articulation and reading from the lip. He was the inventor of the two-handed alphabet now in general use in Great Britain. The "Didascalocophus" was republished in the "American Annals of the Deaf and Dumb" for Jan. 1857. The editor, Prof. Porter, remarks of it: "It is a work of such preëminent ability, and so replete with sound principles and important suggestions of practical value, that it ought to be familiarly known to every instructor." In 1690, John Conrad Amman, a Swiss physician, residing at Haarlem, undertook the instruction of a girl deaf and dumb from birth. His methods were founded on articulation. His success was decisive; but it was not until his essay giving an account of his processes, and entitled *Surdus Loquens* (the "Speaking Deaf Man"), was passing through the press, that he learned what others had done in this field, and commenced a correspondence with Wallis. He subsequently published an enlarged edition of his treatise, under the title of *Dissertatio de Loquela*. In 1679 a deaf mute from birth in France, named Guibal, made his will in writing; it is not known who was his instructor. In 1667 F. M. Van Helmont published a small tract in Holland, entitled *Alphabetum Naturæ*, in which he explained the process of reading on the lip, or learning what another person says by watching the motions of his lips in speaking. About the commencement of the 18th century, the instruction of deaf mutes began to attract the attention of scientific men throughout Europe. In 1704 Kerger published a narrative of the results of his efforts. His sister was associated with him in the work of instruction. The means he used were drawing, pantomime, articulation, and writing. He does not seem to have employed dactylology, but he had cultivated the language of signs with success. Contemporary with Kerger was the pastor Georg Raphel of Lüneburg, of whose 6 children 3 were deaf and dumb. Paternal affection had inspired him with zeal and skill in their instruction, and in 1718 he published, for the benefit of others, the result of his labors. A few years later, Otho Benjamin Lasius gave to the world the narrative of his process of instruction of a deaf and dumb pupil. He had taught articulation and writing, and at the end of 2 years his pupil could answer important questions on religious subjects. The pastor Arnoldi was a contemporary of Lasius; he gave instruction to the deaf and dumb, using for the purpose all the methods previously employed—articulation, drawing, dactylology, writing, and the natural signs. Samuel Heinicke was, however, by far the most distinguished of the early teachers of the deaf and dumb in Germany. He had become interested in the instruction of a deaf and dumb child as early as 1754. In 1772 he had 4 deaf-mute pupils, to whom several others were afterward added. In that year he removed to Leipsic at the invitation of the elector of Saxony, and opened a school for the deaf and dumb there with 9 pupils, the first ever established or supported by the civil government, and which is to this day in existence and prosperity. His method of instruction was by articulation and reading on the lip. His success was very considerable, and his noble and generous character endeared him greatly to the people of Germany. In a controversy with the abbé de l'Épée on

the merits of their respective modes of instruction, he appears to less advantage than in any other part of his career.—In France, Father Vanin or Farnin, a member of the order of Christian brothers, attempted the instruction of deaf mutes toward the middle of the century by means of pictures and sensible objects. The ideas thus conveyed seem to have been very crude and imperfect. Rousset of Nîmes also made some efforts for their instruction about the same time. A more remarkable and successful teacher of these unfortunates was Jacob Rodriguez Pereira, a Spaniard of Jewish extraction, who commenced their instruction in 1743, and in 1749 exhibited some of his pupils before the academy of sciences at Paris. From the report of that committee it appears that his success had been extraordinary for that period; it would even be considered creditable to any of our institutions at the present day. "The pupils," say the committee, "were able to understand whatever was said to them, whether by signs or by writing, and replied either *viva voce* or by writing; they could read and pronounce distinctly all sorts of French expressions; they gave very sensible replies to all questions proposed to them; they understood grammar and its applications; they knew the rules of arithmetic, and performed exercises in geography; and it appeared that Pereira had given them, with speech, the faculty of acquiring abstract ideas." Pereira carefully concealed, even from his own family, the methods he employed in the instruction of the deaf and dumb, though he offered to impart them to the government for a large sum, which was refused. It was his intention to leave them, it is said, as an heirloom to his family, but a fire which occurred soon after his death destroyed all his papers, and thus prevented their being benefited by them. He himself had attained position and wealth by his instruction of the children of some noble families, and by the address with which he followed up his advantages. Saboreux de Fontenai, one of his most distinguished pupils, published after his death an account of the means adopted by his teacher for the instruction of the deaf and dumb. From this we learn that, beside the ordinary methods of articulation, reading from the lip, and the manual alphabet, he had invented a syllabic dactylology, by the use of which he could communicate very rapidly with his pupils, and having thus supplied them in a short time with an extensive vocabulary, he was able to conduct their further education with little more difficulty than would be experienced in instructing speaking pupils. Ernaud appeared a few years later before the academy of sciences, to solicit their attention to his efforts in behalf of the deaf and dumb. His pupils do not seem to have made great advancement in education, but he had been successful in restoring hearing to several who were congenitally deaf. The abbé Deschamps of Orleans is deserving of credit for his philanthropy, at least. Commiserating the condition of the deaf mutes, he devoted his life and fortune to the work of teaching them, but unfortunately adopted the system of articulation, and met with but indifferent success. In 1779 he published his *Cours élémentaire d'éducation des sourds-muets.* The man, however, to whom the deaf and dumb of the world are more indebted for the means of education than any other, is the abbé de l'Épée. His natural disposition, habits, early training, and education, had fitted him for a philanthropist, and when two young deaf-mute girls were thrown in his way under such circumstances as to call forth his sympathies, he entered upon the work of their instruction with a zeal which knew no abatement to the day of his death. His first pupils were gathered in 1755, and entirely from the indigent deaf and dumb. To them alone did he devote himself, refusing the children of the rich, and expending with the most judicious prudence the income of his little patrimony for their support and education. At the commencement of his labors he had read nothing on the subject of the instruction of deaf mutes, and it was not till the second year of his teaching that he saw a copy of Bonet's treatise, and still later that of Amman. He tried at first the method of articulation, but the number of his pupils increasing he became dissatisfied with the result; and remembering the principle which he had learned in youth, that "there is no more natural and necessary connection between abstract ideas and the articulate sounds which strike the ear, than there is between the same ideas and the written characters which strike the eye," he sought for some medium other than articulate sounds by which to represent to the minds of these deaf-mute children the ideas which he wished to convey to them. This medium he found in the language of signs, that natural method of communication by which the most savage tribes of different languages and countries are able to converse to a certain extent with each other. He found this existing to a considerable degree among the uneducated deaf and dumb, as being the only means by which they could make known their physical wants. This language he amplified, improved, and systematized, with the intention of making it an equivalent of ordinary language, so that the process of instruction should be a mere translation of the ideas of written language into the language of signs. It is alleged, and with some truth, that he forgot in this process that the minds on which he was at work possessed but few ideas, and that to make a sign to them of whose meaning they had no conception, and then to show them that that sign was equivalent to a word of whose meaning they were also ignorant, was but to use an algebraic formula—to tell them that $x=x$. That the good abbé too often mistook signs for ideas is probably true; yet there is abundant evidence that his pupils comprehended very clearly much of what he communicated to them. The full advantages of the sign language, and its

capacity for full and free intercourse, and for more ready, complete, and extensive expressions of thought and feeling than any written language, seem not to have been appreciated by him, at least not to the same extent as by his successor; but to the abbé de l'Épée belongs without question the honor of having demonstrated the capability of the natural language of signs for the instruction of the deaf and dumb, when collected in masses; and also of having been the first to collect together indigent deaf mutes in any considerable number for education.—In 1760, 5 years after the opening of De l'Épée's school in Paris, Thomas Braidwood of Edinburgh advertised that at his academy in that city he taught the dumb to speak, and also cured impediments in the speech. Articulation was taught, and little or no attention given to the language of signs. At a period a few years earlier, Henry Baker, the naturalist and microscopist, had given some attention to the instruction of deaf mutes in articulation. Both Baker and Braidwood kept their processes secret, and Braidwood succeeded in monopolizing in his own family and near relatives the business of the instruction of the deaf and dumb for 60 years. In 1783 Braidwood removed his school to Hackney, near London, where he died in 1806. His widow, assisted by her grandchildren, maintained the school till 1816, when it was given up. Thomas, the elder of the two grandsons, took charge of a new institution at Edgebaston, near Birmingham; and John, the younger, went at first to Edinburgh, and after a year or two to Virginia, where he attempted the establishment of an institution for deaf mutes; but though warmly seconded by several gentlemen of wealth and influence, he was so addicted to habits of intemperance, that he was under the necessity of giving it up. The processes of the Braidwoods, though guarded from the public with such jealous care, seem to have differed in no important respect from those of Wallis and Dalgarno. Their success, according to the testimony of impartial observers, was not equal to that of the abbé de l'Épée, and was very far inferior to that of Sicard; and though highly commended in a work published in 1783 by an American gentleman whose child had been educated there, under the title of *Vox Oculis Subjecta*, yet in the majority of instances their system made the pupils mere parrots rather than intelligent, thinking, educated men and women. Dr. Watson, a nephew of the elder Braidwood, who acquired his knowledge of the art of instructing the deaf and dumb from his uncle, and afterward practised it at the asylum in Kent road, London, made many improvements in his processes, and, mingling judiciously the use of natural signs with articulation, succeeded in giving to his pupils a much better education than Mr. Braidwood had ever imparted.—Meantime in France the abbé Sicard, a hearing pupil of De l'Épée, and at the time of his death at the head of an institution for deaf mutes at Bordeaux, had succeeded him at Paris. Though inferior to his master in philanthropy, he was intellectually his superior, and soon found opportunity to improve the methods of instruction in the institute, which was now under government patronage. He expanded and simplified the sign language, and no longer bound it to the conventional rules of written language. Surviving the reign of terror and the administration of Napoleon, in neither of which it had greatly prospered, the royal institution for deaf mutes, as it was called under the Bourbons, saw brighter days, and under the direction of Sicard and Bebian became the leading institution of its class in Europe.—In 1815 several gentlemen in Hartford, Conn., whose interest in the education of the deaf and dumb had been primarily awakened by the fact that the interesting and lovely daughter of one of their number, an eminent physician of the city, was a deaf mute, sent the Rev. Thomas H. Gallaudet, a young and highly educated clergyman, to Europe to qualify himself to become a teacher of the deaf and dumb. Mr. Gallaudet sailed, May 25, 1815, for Liverpool. Arrived in England, he immediately sought the accomplishment of the object of his mission; but found himself thwarted by the influence of the Braidwoods and their relatives, who refused to communicate to him their alleged secret processes, except on condition that he should remain 3 years under instruction, and then take one of Dr. Watson's assistants, or John Braidwood, then in America, into partnership with him. As the parties who had sent out Mr. Gallaudet had contemplated no such plan, and as it was not only unnecessary but illiberal, Mr. Gallaudet refused to enter into such an arrangement; and after attempting in vain to obtain the requisite instruction at Edinburgh, where Mr. Kinniburgh, a pupil of the Braidwoods, was teaching, he visited France, was cordially received and cheerfully instructed by the abbé Sicard, and after 3 months of careful investigation of the processes adopted by the abbé, returned to the United States, bringing with him M. Laurent Clerc, an educated deaf mute, and one of the abbé's most successful teachers. On April 15, 1817, the New England, or, as it was soon afterward named, the American asylum for the deaf and dumb, was opened at Hartford, with Mr. Gallaudet for principal, and M. Clerc as assistant teacher. It received a donation of $5,000 from the state, which was subsequently expended in the education of indigent deaf mutes, and in 1819 from congress the grant of a township of land in Alabama, which by careful management eventually produced a fund of nearly $300,000, the income of which is applied toward defraying the current expenses of the asylum. The other institutions for the deaf and dumb having been established at a later date, and adopting the same general system of instruction with the American asylum, the method in use in this country may properly be termed the American system.—It may aid in giving a clear idea of the instruction of the deaf and dumb, if we devote a little space to the consideration of

the three systems which have been adopted in different countries. I. The system of Wallis, Pereira, Heinicke, and Braidwood proceeded on the theory that articulation is necessary to the clear comprehension of thought; that though signs may communicate vague ideas, there can be no precision of thought without words. This theory has been so utterly overthrown within a few years past that it is not probably maintained by any intelligent instructor of the deaf and dumb at the present day; but the system of instruction inaugurated under it is still practised to a considerable extent on the continent of Europe. Under this system the first 2 years of instruction were devoted to learning articulation almost exclusively; this was effected by placing before the pupil a written or printed word, which the teacher pronounced slowly and audibly, causing the pupil to place his hand upon his throat and to watch his lips as he did so. The pupil was then required to make the attempt to pronounce the word himself; and after repeated trials, if possessing good powers of imitation, he generally succeeded. Another word was then acquired in the same way, and so on. It must be obvious, however, that unless the idea of the meaning of the word was conveyed to the mind of the pupil by some other process, his repetition of these words must be like that of a parrot; and this can only be accomplished by signs of some sort. There is a marked difference in deaf mutes in regard to their ability to acquire the power of articulation so as to be able to speak intelligibly; those who have become deaf after having learned to speak, and those whose vocal organs are pliable, and who possess the imitative faculty in a high degree, acquire the power of articulation with great readiness; while those whose vocal organs are rigid, who are congenitally deaf and dumb, or who possess sluggish intellects, find great difficulty in acquiring the power of speech. Most deaf mutes who speak use a monotonous tone, and some a harsh and unpleasant one, while others modulate the voice without any reference to the sense. Occasionally, though rarely, one is found who, by thorough familiarity with the structure and action of the vocal muscles and long and patient practice, has acquired the art of speaking so well as to excite no suspicion of deafness. Probably no instructor in articulation ever taught it so successfully as Pereira. His pupils, Saboreux de Fontenai and D'Azy d'Étavigny, mingled freely in society, and were in the constant habit of conversing fluently; both were deaf mutes from birth, but there is abundant evidence that nothing in their tones of voice indicated that they were deaf. Seguin even affirms, in his life of Pereira, as a fact of which he was personally cognizant, and which was well known, that Pereira himself being a native of Spain, and speaking with a Spanish accent, all his pupils spoke with the same accent. The mechanical art of articulation and of reading on the lip being acquired, the pupil is thenceforth taught the meaning of words and the sciences in much the same way as a child who can speak. II. The system of the abbé de l'Épée, as improved by Sicard and Bebian, differs from the preceding in every respect. Starting with the principles that there is no necessary or inevitable connection between the word which is the arbitrary sign of a thing and the object for which it stands, and that every idea of which the human mind is capable may be expressed by one or more signs, signs too which even the uneducated can generally understand, the process first attempted was to fix in the mind of the pupil the signs which represented simple objects, and those which readily attracted his attention, such as clothing, food, drinks, parts of the body, the ground, water, grass, fruits, vegetables, domestic animals, men, women, &c.; next, the various relations and circumstances of themselves and others, such as the school, institution, college, officers, domestics, mechanics, laborers, merchants, &c. These attained, subjects more abstruse were represented by the same language of signs, such as the idea of God and spiritual beings, facts of history, science, philosophy, chemistry, numbers, measures, weight, time, &c.; then the organic qualities of man and animals, diseases, properties of matter, action of the body, of the mind, and finally of the moral nature. At an early period instruction in written language is commenced, and the pupil is required to write out narratives communicated to him in the sign language, or to relate by signs facts which he has been made to read. As he advances, he is exercised in the same way on abstract ideas. Having thus acquired two languages, that of signs and written language, his education progresses much in the same way as that of ordinary children, except in the mode of communicating knowledge. The sign language is the natural mode of expressing ideas between individuals who cannot speak the same language; and although the usage of different countries would of course cause differences of dialect, yet with such care have the signs in ordinary use been selected, that the Rev. W. C. Woodbridge affirms that "he has employed it or seen it employed with success, in conversation with an American Indian, a Sandwich islander, a Chinese, and with deaf mutes in various parts of the United States, and in England, Scotland, France, Germany, Switzerland, and Italy." III. The American system may best be described in the words of one who took part in its development, and who had practised it for many years, the late Rev. W. C. Woodbridge: "Mr. Gallaudet has combined the fundamental principle of Heinicke, 'first ideas, then words,' with that of De l'Épée, that 'the natural language of signs must be elevated to as high a degree of excellence as possible, in order to serve as the medium for giving the ideas clearly, and explaining them accurately.' He has added another of no small importance, that as words describe rather the impressions or states of mind produced by external objects than those essential qualities

which are beyond our reach, the process of learning them would be facilitated by leading the pupils to reflect on their own sensations and ideas; and he states as the result of his experience, that among deaf mutes of equal capacities 'those who can be led to mark or describe, with the greatest precision, the operations of their own mind, uniformly make the most rapid progress in the acquisition of written language, and of religious truth.' A leading object therefore, in connection with the first lessons, in which sensible ideas are presented and named, is to establish a free communication with the pupil in the sign language in reference to his feelings and thoughts as excited by the objects which he sees, or the events of his own life. He easily comprehends those of others, and is thus led to learn the names of the simple emotions and acts of the mind. Hence he is brought to think of an invisible agent which we term the soul, as the feeling and percipient being; and by a natural transition is led, by the use of signs alone, to the Great Spirit as the first cause; to his character as our creator and benefactor; and to a knowledge of his law and our future destiny. In this manner the deaf mutes in the institutions of this country are made acquainted with the simple truths of religion and morality in one year, a period in which, in most European institutions, they are scarcely advanced beyond the knowledge of sounds, and the names of sensible objects, qualities, and actions, or the most common phrases. By communicating this instruction in the natural sign language, pupils whose inferior capacity or advanced age would not allow them to acquire enough of written language to receive religious truth through this medium, have been early prepared to enjoy its blessings and hopes, and feel its sanction as a restraint upon their conduct, which renders their government more easy, while it aids them in the formation of correct habits." Another peculiar feature of the American system introduced by Mr. Gallaudet, and now generally adopted in American institutions, is conducting the daily and weekly devotional exercises in the sign language. The English schools, which began by regarding articulation as of the first importance, now make extensive use of the language of signs, as do most of the continental schools; while the French schools and those of this country usually have a class in articulation, generally composed of those who had learned to talk before becoming deaf, or the flexibility of whose vocal organs renders them appropriate subjects for the exercise. The signs are divided by the teachers of deaf mutes into two classes, descriptive and methodical; the first consisting of those which portray the object, or, by some accepted conventionalism, imply some mental action or abstract idea; the second representing those connectives, inflections, and other changes in the form of expression, which vary the meaning of language. The latter are of course arbitrary, but are at the present day generally agreed upon and easily acquired by the learner.

In the acquisition of so large an amount of ideas as is necessary for a good education to the deaf mute, embarrassed as he is by his infirmity and by the necessity of acquiring two languages, it must be evident that the period of 3, 4, or 5 years is utterly inadequate, when a child endowed with all his faculties has from 12 to 15 years for the attainment of an ordinary education; and it is a matter of congratulation that the course is very generally extended to 7 or 8 years, and that in several institutions a high class, for the prosecution of higher branches of study, is established. These classes give to the deaf mute who is desirous of intellectual culture opportunities almost equivalent to those of a collegiate course. In Paris a "class of perfection," answering to the American high class, was established some years since in the national institute, through the liberal bequest of Dr. Itard, who was for many years physician to the institute.—We have adverted in the commencement of this article to the complete mental isolation of the deaf mute, but it may be of interest in a psychological point of view to give in a few words the result of an extended series of inquiries made of intelligent educated deaf mutes some years since in Europe and this country, respecting their ideas before receiving any education. Of some thousands to whom such inquiries as the following were addressed: What were your ideas of God? What of the creation of the world? What of the sun, moon, and stars? What did you suppose to be the object of public religious services on the Sabbath? &c., the answers were in nearly all cases such as these: "I had no idea of God;" "I supposed God to be a strong and cruel man, who made the thunder and lightning to frighten us;" "I supposed the world had always been;" "I had no ideas of the origin of the world;" "I supposed the earth was very much larger than the sun;" "I thought the sun was a man, and the moon another;" "I thought people went to church to worship the minister;" "I supposed it was a holiday, and the people were playing." These answers might be greatly multiplied, but those already given are sufficient to show that in mental condition the deaf mute is in no respect above the ignorant and untutored savage. Their mental operations before receiving education are very slow, and the mind seems to be in a torpid state from which the discipline of an education rouses it. Under the influence of the thorough course of instruction adopted in our American institutions they improve rapidly, becoming respectable scholars, and developing vigorous and healthy intellects. The results of education in training the deaf and dumb to self-support and independence have been very remarkable. Of more than 1,000 pupils who have spent more or less time at the American asylum, the directors and officers after extensive correspondence cannot find more than one or two who are not comfortably supporting themselves, and many of them their families. A considerable number have accumulated property. Some have attained distinction in the

fine arts. In the French magazine *L'Impartial* (devoted to deaf mutes) for Jan. 1856, is an account of two first class prizes having been awarded to deaf mutes at the Paris industrial exhibition of 1855. One was to a M. Maloisel, a sculptor, for an instrument for duplicating choice statues, &c., in any material; the prize was the great medal, and an annuity of $60 per annum. The other was to a M. Richardin for a machine for polishing daguerreotype plates, a process always hitherto performed by hand. There were also several smaller prizes conferred on deaf mutes. When it was proposed to erect a monument to the late Dr. Gallaudet, the deaf mutes who had been his pupils came forward and asked the privilege of taking the whole matter into their own hands. The plan was drawn by a deaf mute, and a copy of it lithographed by deaf mutes. The monument, which is really one of the finest conceptions in the way of a commemorative column, is entirely due, in conception, design, and execution, to deaf mutes. Within the past 5 or 6 years the educated deaf and dumb in this country have been in the habit of holding an annual convention for their improvement, and they have in these conventions given evidence of practical talent of a high order. In Europe, owing mainly to the density of the population, and the difficulty which the laboring classes, even when possessed of all their faculties, find in procuring subsistence, it has been found necessary to form associations for the assistance of deaf mutes. Such societies have been established in Paris, Berlin, Vienna, and perhaps in some other cities. Workshops are hired or erected by these societies, the raw material procured at the lowest price, and they are furnished with them free from rent, and without the necessity of making advance payment on their stock. In some cases they are also boarded at a very low rate, or an allowance is made them weekly toward defraying the expense of board.—The proportion of the deaf and dumb varies greatly in different countries. In China it is said to be very small; whether the prevalent practice of infanticide may not reduce the number by destroying those children whose faculties seem imperfect, is a question. In Africa the missionaries report that there are very few cases among the native population; but we suspect that careful and thorough investigation would bring to light more than are now supposed to exist. The following table, prepared from the published census reports of the several countries, and from other authentic sources, gives, it is believed, a tolerably accurate view of the prevalence of the infirmity in Europe and America. There is reason to believe, however, that in Switzerland, the grand duchy of Baden, and perhaps also in Austria, cretins have been enumerated with deaf mutes. As a general rule, the ratio of deaf and dumb persons to the population is larger in mountainous countries and in districts which are so far isolated as to render intermarriage of relatives frequent:

Countries.	Number of deaf mutes.	Date of census.	Ratio to population.
Great Britain	12,553	1851	1 in 1,670
Ireland	4,747	1851	1 in 1,880
Spain	12,000	1851	1 in 1,500

Canada	1,343	1851	1 in 1,372

—*Causes of deafness.* About $\frac{3}{5}$ of the cases of deafness are congenital. The causes of this are usually either hereditary transmission, direct or indirect; intermarriage of near relatives; or grief, fright, or other violent emotions of the mother during pregnancy; and sometimes intemperate or vicious habits on the part of one or both parents. In hereditary transmission of the infirmity, it often occurs that the children of deaf mutes hear while their children are deaf and dumb. The infirmity, too, is often perpetuated in collateral branches of the family. Were it necessary, volumes of statistics might be compiled to show the disastrous results of the intermarriage of near relatives, in inducing not only congenital deafness, but blindness, insanity, and, more often than either, idiocy. The following table presents an interesting summary of the results of inquiry in England, Ireland, France, and different sections of our own country:

Statistics of American Asylum at Hartford.—Of 542 cases, 95 had either parents, grandparents, uncles, aunts, or cousins deaf and dumb; 27 more remote relatives deaf and dumb. Of 911 families, 728 had each only 1 deaf and dumb child; 109 had 2; 41 had 3; 18 had 4; 11 had 5; 2 had 6; and 2 had 7.

Statistics of National Institution, Paris.—Of 102 families, 81 had only 1 deaf and dumb child; 9 had 2; 7 had 3; 3 had 4; 1 had 5; 1 had 7.

Statistics of Yorkshire Institution, at Doncaster, England.—Of 110 families, 74 had but 1 deaf and dumb child; 17 had 2; 7 had 3; 2 had 4; 1 had 5.

Statistics of Report of Secretary of State, Ohio.—Of 407 families, 327 had but 1 deaf and dumb child; 49 families had 2 each; 17 had 3; 8 had 4; 2 had 5; 2 had 6; 1 had 7; 1 had 9. Of these 407 families, the parents of 47 were known to have been cousins. Of these 47, 30 had 1 deaf and dumb child; 10 had 2; 4 had 3; 2 had 4; 1 had 5.

Statistics of Ireland, prepared by Dr. Wildes.—Of 170 families where the parents were known to be first cousins, 109 had 1 deaf and dumb child; 17 had 3; 3 had 4; 1 had 7, and 1 had 8. In 471 cases deafness was found to be hereditary, of which 249 were cases in which the father or some relative of his was deaf and dumb, and 222 where the mother or some relative of hers was deaf and dumb.

Where not congenital, deaf-mutism is usually the result of disease or accident occurring in early life. The diseases which most frequently produce this result are fever in some form, continued, typhus, or yellow, scarlatina, that ter-

rible scourge of childhood, inflammation of the brain or ear, dropsy of the brain, convulsions, and local paralytic affections. In Europe the small pox is also an important agent in causing this infirmity. The following table of causes of deafness when not congenital is made up from the results of a careful and thorough inquiry in 4 different countries:

Reports of what institution or country.	Whole number of cases not congenital.	Fever, continued, spotted, typhus, or yellow.	Scarlatina.	Pneumonia.	Measles.	Small pox.	Whooping cough.	Inflammation of brain or ear.	Scrofula and Rickets.	Mumps.	Hydrocephalus.	Palsy.	Convulsions and Worms.	Accidents.	Erysipelas.	Unknown.

—*Nature and cure of deafness.* The diseases to which the ear and parts adjacent are subject, and most of which may cause or accompany deafness, are the following: Malformation of the external ear; a diminished or excessive secretion of the wax; obliteration or enlargement of the auditory passage; extraneous matter in the Eustachian tube; a diseased or paralyzed condition of the auditory nerve; disease of the brain; disease of the throat and tonsils; the growth of polypi from the lining membrane of the auditory passage; inflammation or structural disease of the tympanum. Numerous attempts have been made, both by men eminent for science and by quacks, to restore hearing to the deaf; but, with few exceptions, without success, where the deafness was nearly or quite complete. There are not probably on record more than 20 cases of complete recovery where the deafness was entire. Of those who have devoted attention to this subject, none probably ever brought the entire appliances of science to bear upon it more fully than Dr. Itard, the celebrated surgeon and philanthropist. He made himself completely master of the anatomical structure of the ear, of its physiology, and of its diseases. He tried during the long period of 40 years every remedy which seemed to give any promise of success, even to the terrible moxa and the actual cautery, but could report success in but two cases out of the hundreds he treated. Dr. Deleau, another eminent surgeon, also made a great number of experiments, but with no better success.—We have already traced the origin of the early deaf and dumb institutions of France, Great Britain, and Germany. From these great centres they have spread over the whole of Europe, until now there are more or less in each country, and many of them of very superior character. In Great Britain none of the original schools organized by the Braidwood family are in existence; the oldest institution being that of London, founded in 1792, which is also the largest in Europe, numbering over 300 pupils. In 1825 there were in the United Kingdom only 9 institutions for deaf mutes, and these but indifferently sustained; in 1851 there were 25, all well sustained, employing 81 teachers, and containing over 1,400 pupils. In France for many years there were no institutions for deaf mutes except those at Paris, Bordeaux, and Orleans; there are now 44, with 63 teachers, and 1,642 pupils. The school founded by De l'Épée is still in existence as the national institute for young deaf mutes in Paris, and is, after that of London, the largest in Europe. The school of Heinicke still exists at Leipsic, but does not now follow Heinicke's methods. After France, Prussia is next in rank in her devotion to the education of deaf mutes. She has 25 schools, with about 60 teachers and 853 pupils. Austria has 19 institutions, with 71 teachers and 643 pupils. Belgium has 10, with 395 pupils; one of these, that of Bruges, under the direction of the abbé Carton, has become widely known from the writings of its able director, and particularly from his interesting narrative of the deaf, dumb, and blind girl, Anna Temmermans. Bavaria has 9, with 21 teachers and 229 pupils, and has made so thorough an investigation of the condition of its deaf and dumb and its blind inhabitants, that we may reasonably expect hereafter great progress. The smaller states of Germany are well supplied with schools for deaf mutes, but many of them are very small. Italy has 22, several of which have only from 5 to 10 pupils; the whole number of pupils is only 442. Russsia, Spain, and Portugal are very poorly supplied with schools for the education of this class of unfortunates. We subjoin a table giving the population of each country in 1850, with the number of schools for deaf mutes and pupils at the same date:

Countries.	Population, 1850.	Number of schools.	Number of pupils.
England.....	17,927,609	13	854
Ireland.....	6,515,794	7	288
Scotland.....	2,888,742	5	259
France.....	35,783,170	44	1,642
Germany.....about	10,500,000	46	577
Austria.....	36,514,397	19	643
Prussia.....	16,331,187	25	853

Russia.....	62,088,000	5	315
Total.....	240,354,988	227	7,344

—We have already referred incidentally to Mr. Gallaudet's visit to England in 1815, and the subsequent organization of the American asylum for the deaf and dumb at Hartford. That institution, the parent of American deaf-mute institutions, is still vigorous and flourishing. Mr. Gallaudet resigned the superintendency in 1830, and was succeeded by Mr. Weld, then at the head of the Pennsylvania school. On the decease of Mr. Weld in 1853, the Rev. W. W. Turner, the present principal, was elected. The asylum has now (1858) 17 teachers, 246 pupils, and has graduated over 1,100 deaf mutes. The New York institution, the largest in this country, and equal in size to any in Europe, was organized in 1818, but owing to a variety of causes met with but indifferent success till 1831, when its present president, Harvey P. Peet, LL.D., was called to the superintendency. Under his care it has risen to the first rank of public institutions for deaf mutes, in the extent and thoroughness of its course of instruction and the ability of its corps of instructors. It has recently removed to its new edifice at Fanwood, on the Hudson river railroad, about 9 miles from the city hall, New York, where it has accommodations for about 500 pupils. The new buildings are unsurpassed in magnificence and cost by any edifice for the deaf and dumb in the world. About 37 acres are included in the grounds. The entire expense of buildings and grounds was $563,000. The Pennsylvania institution was organized by Mr. Clerc, the deaf mute who accompanied Mr. Gallaudet to this country in 1816, and Mr. Louis Weld, then a teacher in the Hartford asylum, became its principal. On his resignation in 1830, Mr. Abraham B. Hutton, the present principal, was elected. The institution is in a highly prosperous condition. The Kentucky asylum was incorporated in 1823. Its principal, Mr. J. A. Jacobs, like those of the New York, Pennsylvania, Virginia, and Ohio asylums, was educated for his position at Hartford. Mr. Jacobs has distinguished himself among the highly intellectual corps of superintendents of deaf and dumb institutions as an able writer and a vigorous thinker. The Ohio institution, organized in 1829, has been ably managed from the first, and is one of the most efficient of the western schools. It has had 3 principals, Mr. Hubbell, Mr. Cary (both deceased), and Mr. Stone, the present incumbent. All had been teachers at Hartford. The Virginia institution, located at Staunton, was organized in 1838. It contains a department for the blind. It is finely situated, and its buildings and grounds are very attractive. The other institutions have all been organized since 1845, and most of them are state institutions. The western states have generally been very liberal in their appropriations for the erection of suitable buildings and the support of the institutions; but in some of them partisan politics have been allowed to exert an unfavorable influence in inducing frequent changes of superintendents. The table on the next page gives a comprehensive view of the present condition of the institutions in the United States, carefully compiled from their latest reports. From this it appears that there are in these institutions about 1,800 deaf and dumb pupils, which, estimating the proportion of deaf mutes as 1 in 2,000 of the population, would give ¼ of the whole number as under instruction. Large as this proportion is, it comprises, according to the tables of Dr. Peet, published in 1852, only about ⅔ of the number who should be under instruction. The term of life with the deaf mute is shown by the census of England and the United States to be below the average. In England 47 per cent. of the whole number of deaf mutes are under 20 years of age; in the United States about 50 per cent. are under 30 years. The deficiency of schools in this country is mainly in the southern and western states, and is likely to be remedied in the course of a few years. In Europe, and especially in Austria, Spain, Portugal, and, above all, Russia, the provisions for their education are very meagre and defective. The advancing light of civilization will undoubtedly remedy this in time, but many generations of the unfortunate deaf and dumb must first perish in ignorance.—The number of deaf mutes who have attained to eminence in science and art is much smaller than that of the blind; but occasionally we find a superior intellect rising above the trammels of infirmity, and making good its claim to the possession of genius. Among those who have distinguished themselves for intellectual ability, Jean Massieu deserves notice; the fellow pupil of Clerc, and afterward, under Sicard, his fellow teacher, he displayed metaphysical powers of a high order. The late Walter Geikie, R. A. S., of Edinburgh, was a painter and designer of extraordinary ability, and it is no exaggeration to say that the title of the "Scottish Teniers," which was very generally applied to him, conferred more honor on the ancient than the modern painter. He left about 1,300 sketches, many of them etched on copper by himself; and as representations of common life in Scotland they are unsurpassed. We might add to this catalogue such names as that of the linguist Montbret and others, who have distinguished themselves in their several spheres; but the living deaf mutes who have achieved distinction are far more numerous than the dead. Laurent Clerc and Prof. Lenoir, eminent as teachers in deaf and dumb institutions; Levi S. Backus, editor of the "Radii;" Edmund Booth, editor of the "Eureka;" Albert Newsam, an artist of decided genius; M. Maloisel, the French sculptor; and Mrs. Mary Tolles Peet, whose lyrical powers give evidence not only of poetic genius but of rhythmic ability entirely independent of the accident of hearing, are among the most distinguished. As education progresses among the deaf and dumb, we may confidently expect the development of higher intellectual powers, and a more facile and skilful use of them.

TABULAR VIEW OF DEAF AND DUMB INSTITUTIONS IN THE UNITED STATES, 1858.

Name.	Location.	Date of opening.	Date of information.	Number of pupils who are deaf mutes.	Males.	Females.	State beneficiaries.	Cost of the present buildings and grounds.	Annual amount received from state for ordinary purposes.	Amount from paying pupils.	Amount of ordinary expenses.	Permanent funds.	Annual charge to paying pupils.	Name of principal or superintendent.	Number of instructors, including principal.	Number of instructors who are deaf mutes.	Number of do., female.	Number educated previous to 1857.

EMINENT DEAF MUTES.

Juan Fernandez de Navarette, painter, born 1526, died 1579, commonly known as El Mudo; he was regarded as the Titian of Spain. He painted many of the finest pictures of the Escurial.

Pedro de Velasco, a brother of the constable of Aragon, born 1540, a priest of the Roman Catholic church; —— Velasco, a brother of the preceding, born 1544, an officer in the Spanish army. These were pupils of Pedro Ponce de Leon, and were the first deaf mutes who attained distinction.

Sir Edward Gostwick, magistrate, born about 1610; —— Gostwick, painter; brothers, mentioned by Defoe as having obtained distinction; they were deaf from birth. The younger attained to eminence as a painter of portraits.

Emanuel Philibert, prince of Savoy, born about 1650, died about 1700, a pupil of Ramirez de Carion, who acquired the ability to read and speak 4 languages.

Miss Loggin, authoress, born about 1700; also mentioned by Defoe, who speaks of her as a miracle of wit and good nature.

Saboreux de Fontenai, born about 1730, one of the most distinguished of Pereira's pupils, master of several languages, and an author.

Jean Massieu, teacher of deaf mutes, born 1772, died 1846, was the most eminent of Sicard's pupils, and possessed extraordinary logical powers. He was director of the deaf-mute institute at Lille.

Eugène, Baron de Montbret, secretary interpreter to the minister of foreign affairs, France, born 1785, died 1847. After Cardinal Mezzofanti, Baron de Montbret was perhaps the best linguist in Europe. He was more familiar than any other man with the Asiatic languages. He became deaf at the age of 5 years. He left $60,000 and a library of 60,000 volumes to the city of Rouen.

Laurent Clerc, professor at Paris and Hartford, born 1785, was associated with Mr. Gallaudet in founding the American asylum for deaf and dumb, and had previously been a professor at Paris under Sicard. He is still living at Hartford. His autobiography, letters, and addresses have been published.

Mrs. Charlotte Elizabeth Tonna, authoress, born 1792, died 1846. Mrs. Tonna was one of the most voluminous religious writers of the present century, and her works have had a large circulation. She became deaf in childhood, at the age of 9 or 10.

Walter Geikie, painter and engraver, born 1795, died 1837, possessed such skill in the portraiture of low life in Scotland that he was known as the Scotch Teniers. A volume of his etchings has been published.

Levi S. Backus, teacher, printer, and editor, born 1803, formerly connected with the deaf and dumb institute at Canajoharie, now discontinued; editor and publisher of the "Radii," at Hamilton, N. Y.

John Kitto, D.D., LL.D., author and editor, born 1804, died 1854. Dr. Kitto was regarded, at the time of his resigning his connection with the "Journal of Biblical Literature," as the ablest biblical scholar then living. He was the editor and a large contributor to the "Cyclopædia of Biblical Literature," author of "Daily Bible Illustrations," "Lost Senses," &c. He became deaf at the age of 13.

Thomas Brown, mechanic, born 1804, has presided over three sessions of the convention of the deaf and dumb. His addresses which have been published exhibit decided talent.

Wilson Whiton, a teacher in the American asylum, born 1805. Prof. Whiton has not, we believe, published any thing, but bears a high reputation for scholarship and intellectual ability.

Alice Cogswell, born 1805, died 1830, one of the most interesting of this unfortunate class. She possessed in a high degree the poetic temperament. It was in consequence of his interest in her that Dr. Gallaudet was led to attempt the education of the deaf and dumb.

George H. Loring, teacher in the American asylum, born 1807, died 1852, was one of the earliest pupils of the asylum. He was a writer of superior ability.

James Nack, poet and author, born 1809, became deaf at the age of 9 years; has an office under the N. Y. county clerk; has published several volumes of poems, the last entitled the "Romance of the Ring" (1859).

David M. Phillips, lieutenant-colonel of governor's horse guards, Louisiana, born 1811, was educated at the deaf-mute institute in Groningen, but has resided in New Orleans since 1831. He has filled many offices with fidelity and distinction, some of them such as it would seem impossible for a deaf mute to fill.

Edwin John Mann, mechanic and author, born 1811, is a graduate of the American asylum at Hartford. He published in 1836 a volume entitled "The Deaf and Dumb; a collection of articles relating to the condition of deaf mutes, &c."

Mrs. Mary Tolles Peet, teacher and poetess, born 1836, has published a number of fugitive poems of great merit. She possesses what deaf mutes seldom attain, an accurate perception of rhythm and melody. She became deaf at the age of 13.

John R. Burnet, farmer and author, was for a time an instructor in the N. Y. institute; now resides at Livingston, N. J., where he has a farm. Is familiar with French and German literature. He has published "Tales of the Deaf and Dumb, with Miscellaneous Poems," and has been a frequent contributor to the "Biblical Repository" and "North American Review."

Ferdinand Berthier, professor at Paris and author, died 1857, wrote an able memoir of De l'Épée, and several addresses which were published.

Professor Lenoir, of Paris, spoken of by Mr. Clerc as a man of decided ability. He is still living.

John Carlin, an artist. Mr. Carlin is one of the most gifted deaf mutes living. As an artist and designer he possesses genius of a high order. He is also a vigorous and able writer. He is a graduate of the Philadelphia institution.

Albert Newsam, artist and engraver. Mr. Newsam stands in the first rank of American lithographic artists. Many of his engravings, designed entirely by himself, are among the best specimens of the art in this country.

M. Maloisel, superintendent of turning shop in Paris institution for deaf and dumb. M. Maloisel has distinguished himself as an inventor. A machine invented by him for executing sculpture received the great medal and an annuity of $60 per annum, at the world's fair in Paris, 1855.

M. Richardin, inventor and daguerreotypist. M. Richardin also received a medal for an ingenious machine for polishing daguerreotype plates—not his first contribution to the improvement of that art.

—The following works may be consulted with advantage by those who would investigate the subject of deaf-mute instruction more fully; the earlier ones, except some 2 or 3 which have been reprinted, are scarce: Juan Pablo Bonet, *Reduccion de las letras y artes para enseñar a hablar los mudos* (Madrid, 1620); George Dalgarno, "Didascalocophus, or the Deaf and Dumb Man's Tutor" (Oxford, 1680), reprinted in the "Annals of the Deaf and Dumb," vol. ix.; John Wallis, "Letter to Thomas Beverley," in the "Philosophical Transactions," Oct. 1698; Joseph Watson, LL.D., "Instruction of the Deaf and Dumb" (London, 1809); "Memoirs of Rev. John Townsend" (Boston, 1831; Mr. Townsend was the founder of the London asylum for the deaf and dumb); Charles Michel, abbé de l'Épée, *La véritable manière*, &c. (Paris; this is De l'Épée's best work; it was translated into English, and published at London in 1801); Charles Baker, "Contributions to Publications of the Society for the Diffusion of Useful Knowledge," &c. (privately reprinted, 1842); Abbé Sicard, several works on the instruction of deaf mutes, all of which are, however, now scarce; Baron de Gerando, *De la bienfaisance* and *De l'enseignement des sourds-muets*, the latter a work of great value; *Annales de l'éducation des sourds-muets et des aveugles*, a periodical published in Paris, 1843–'53; *Le Bienfaitcur*, a periodical, 1853–'56; *L'Impartial*, a periodical, 1856; "Annals of the Deaf and Dumb" (Hartford, 1848–'58); "Tribute to Gallaudet," with an appendix by the Hon. Henry Barnard (Hartford, 1852); reports of the various deaf and dumb institutions in Europe and America; "Life of the Rev. T. H. Gallaudet, LL.D.," by the Rev. Heman Humphrey, D.D. (New York, 1858).

DEAL, a parliamentary and municipal borough, parish, seaport, market town, and watering place of Kent, England, and a member of

the cinque port of Sandwich, built on an open beach on the North sea, between the N. and S. Forelands, 18 m. S. E. of Canterbury, 8 m. N. E. of Dover, and 102 m. by the south-eastern railway E. S. E. of London; pop. in 1851, 7,067. It is divided into Upper and Lower Deal; the former, comprising the residences of the wealthy classes, was a small fishing village in the time of Henry VIII.; the latter, built on 3 streets parallel with the coast, is entirely of modern date, and has most of the business and the bulk of the population. The town contains a spacious esplanade, a public library and reading room, a custom house, a naval yard and storehouse, barracks, a pilot station, a town hall, a gaol, baths, a savings bank, boat-building yards, gas works, a nautical school, national and infant schools, 2 parish churches, a chapel of ease, and places of worship for dissenters. At its S. end is a fortress built by Henry VIII. in 1539, and on the N. stands Sandown castle, now used as a coast guard station. There is no harbor, but vessels of all dimensions ride safely in a spacious roadstead called the Downs, between the shore and the Goodwin sands. The latter lie directly opposite the town, and are the scene of frequent shipwrecks. There is little or no foreign commerce, but a brisk trade in naval supplies is carried on with vessels which, at times to the number of 400 or 500, anchor in the Downs while waiting for favorable winds. Many of the inhabitants are fishermen or connected in some other way with maritime pursuits, and the skill and daring of the Deal boatmen, both as pilots and as wreckers, are almost proverbial; but their occupation is now deserting them. Of the licensed or branch pilots of the cinque ports, 56 are attached to this station. The registered shipping of the port, Dec. 31, 1856, amounted to 18 vessels, with an aggregate tonnage of 299. Number of coasting vessels entered during the year, 72, tonnage 5,335. There were no returns of entrances from foreign ports, nor of clearances of any description. Adjoining Deal on the S. is the suburban village of Walmer, where is situated Walmer castle, the official residence of the warden of the cinque ports. In the same suburb is a royal naval and military hospital, now converted into a coast guard station. There are several martello towers along the coast. The borough unites with Sandwich in sending 2 members to the house of commons.

DEAN (Lat. *decanus*, Fr. *doyen*), in England, an ecclesiastical officer, so called, it is supposed, because he was formerly at the head of ten (lat. *decem*) canons or prebendaries. Deans are of 3 classes. 1. The dean of a cathedral church ranks next to the bishop, and is chief of the chapter, by whom he was originally elected; but in bishoprics erected by Henry VIII. he is now appointed by the crown, while in other sees the chapter are obliged under heavy penalties to choose the royal nominee. All the acts of such communities are in the name of the dean and chapter. 2. Rural deans are usually beneficed clergymen to whom is committed the superintendency of a certain number of parishes. They are the medium of communication between the higher and lower orders of clergy; they appear to have formerly discharged the duties now performed by clergymen called surrogates, and they had their public seals. The office probably existed in England before the Norman conquest, and subsequently falling into disuse, became merged in those of archdeacon and chancellor. An attempt has been made to revive it during the present century. 3. Deans in peculiars are ecclesiastics possessing peculiar privileges and jurisdiction, arising in most instances from royal foundations. Such are the deans of Westminster, St. George's chapel at Windsor, Christ church Oxford, the Arches, the King's chapel, &c., most of whom were originally, as some are now, at the head of capitular bodies. There are also deans of faculties in the universities, and in Scotland deans of guild, who preside over incorporated bodies of tradesmen.

DEAN FOREST, a royal forest of England, in the county of Gloucester; area, about 22,000 acres, one-half of which is now set aside for navy timber; pop. in 1851, 13,566, mostly miners. It was anciently much more extensive than at present, nearly all that part of the county lying W. of the Severn having been included within its limits. It embraces a number of plantations of oak, beech, and other trees, and orchards famous for the production of styre-apple cider. It abounds in coal and iron, and several railways have been constructed from the mines to the Severn, Wye, &c. Dean Forest is divided into 6 parochial districts, and is the property of the crown. The inhabitants pay no county rates, and enjoy a number of ancient privileges.

DEANE, James, M.D., an American physician, the discoverer of the fossil footprints of the Connecticut valley, born in Coleraine, Mass., Feb. 14, 1801, died at Greenfield, June 8, 1858. He removed to Greenfield in 1822, where, after writing in a public office for 4 years, he studied medicine, and practised as a physician and surgeon from 1831 until his death. As a medical writer he was known to the profession by his frequent contributions to the Boston "Medical and Surgical Journal," and by a communication written at the request of the Massachusetts medical society, on the "Hygienic Condition of the Survivors of Ovariotomy," in which he established the morality of the operation. In the spring of 1835 he discovered the fossil footprints in the red sandstone of the Connecticut valley. By means of diagrams and plaster casts he succeeded in calling the attention of eminent scientific men to the subject, and thus gave the first impulse to its thorough investigation, which was afterward prosecuted by Prof. Edward Hitchcock and others. For several years he was a most successful collector of specimens, and American geologists were early convinced of the genuineness of the footprints; but the greatest scepticism existed in England until, in 1842, Dr. Deane prepared a box of the impressions, which he

sent with a communication to Dr. G. A. Mantell, by whom they were placed before the geological society of London; and by means of these, taken in connection with the then recent discovery of the bones of the dinornis of New Zealand, the doubts of Sir Roderic Murchison (then Mr. Murchison), the president of the society, and of Dr. Mantell and Prof. Owen, were removed, and they yielded their assent to the conclusions of Dr. Deane and Prof. Hitchcock. Shortly afterward a discussion arose between the two latter gentlemen as to their respective claims to the credit of the discovery, which appeared in "Silliman's Journal," vol. xlvii. Dr. Deane also published numerous papers in the same and other scientific journals, and in the memoirs of scientific societies, with occasional illustrations; and at the time of his death he was engaged in the preparation of an elaborate memoir upon the whole subject for the Smithsonian institution, with lithographic plates made by himself, by which the color of the rock and the actual appearance of the footprints were reproduced with singular fidelity. These plates were all completed.

DEANE, Silas, an American diplomatist, born at Groton, Conn., died at Deal, England, Aug. 23, 1789. He was graduated at Yale college in 1758, and was a member of the first continental congress in 1774. He was sent by congress to France as a political and financial agent, and arrived at Paris in June, 1776, with instructions to ascertain the temper of the French government concerning the rupture with Great Britain, and to obtain supplies of military stores. But he did not confine himself to his instructions, but made promises and engagements on all sides, which afterward brought the congress into considerable embarrassment. When in September it was determined to send ministers to negotiate treaties, Dr. Franklin and Mr. Jefferson, and, on the declension of the latter, Arthur Lee, were commissioned to join him at Paris, and he assisted in the negotiation of the treaty with France. In consequence of the extravagant contracts he had entered into, he was recalled, Nov. 21, 1777, and John Adams appointed in his place. He left Paris, April 1, 1778, and upon his return, being called upon to give an account of his proceedings on the floor of congress, evaded a complete disclosure upon the ground that his papers were in Europe. He then attacked his fellow commissioners and congress itself in a public manifesto for the manner in which he had been treated, but did not succeed in removing the public suspicion from himself. He afterward published in 1784 an address to the citizens of the United States on the same subject, and returning to Europe, died in great poverty.

DEARBORN, a S. E. co. of Ind., bordering on Ohio, drained by Whitewater river; area, 291 sq. m.; pop. in 1850, 20,166. Part of the surface is level and part hilly; the soil is generally fertile. Limestone is the principal rock. In 1850 this county yielded 938,491 bushels of corn, 70,506 of wheat, 94,108 of oats, and 13,889 tons of hay. There were 47 churches, and 7,461 pupils attending public schools. Capital, Lawrenceburg.

DEARBORN, Henry, an American general, born in Hampton, N. H., in March, 1751, died at Roxbury, Mass., June 6, 1829. He was practising medicine at Portsmouth when, on hearing the news of the battle of Lexington, April 20, 1775, he immediately marched with 60 volunteers, and was at Cambridge early the next day, a distance of 65 m. He was made a captain, was at the battle of Bunker hill, June 17, and accompanied Arnold on the expedition through the woods of Maine to Quebec. In the attack on that place, Dec. 31, he was taken prisoner, and afterward released on parole, and exchanged, March, 1777. He served as major under Gates at the capture of Burgoyne, and distinguished himself and his regiment by a gallant charge at the battle of Monmouth in 1778. In 1779 he served in Sullivan's expedition against the Indians, in 1780 with the army of New Jersey in 1781 at Yorktown, and in 1782 was on garrison duty at Saratoga. At the peace, having emigrated to Maine, he was appointed by Washington in 1789 marshal of that district. He was twice member of congress, and for 8 years, during the presidency of Mr. Jefferson, secretary of war. In 1809 he was made collector of Boston, and on Jan. 27, 1812, became senior major-general in the U. S. army. In the spring of 1813 he captured York, in Upper Canada, and Fort George, at the mouth of the Niagara, but was recalled, and soon afterward placed in command of the military district of New York city. Resigning his commission in the army in 1815, he was appointed, May 7, 1822, minister to Portugal, where he remained 2 years, and was recalled at his own request.

DEATH. With all our science and philosophy we cannot obtain a better definition of death than that it is a cessation of life. Of life itself we know nothing beyond what we can learn from the observation of certain phenomena presented by living organized bodies, as distinguished from those exhibited by inorganic forms. When these vital phenomena cease to present themselves, we have death. Human beings seldom or never reach that term of existence that nature has fixed. Death by disease or violence is the rule, death from old age the exception. When disease terminates life gradually, it is almost impossible to trace the precise changes which lead to the final and fatal result. When, however, death is sudden, as in apoplexy, concussion of the brain, suffocation, and hemorrhage, its immediate cause may be more readily ascertained. The heart, the lungs, and the brain were called the tripod of life by the ancients, who thus metaphorically described the fundamental basis upon which animal existence is erected. Death to either is necessarily death to all, as each of these organs is the source of a function absolutely essential to

life. The cessation of the action of the lungs and heart, organs intimately associated in the movement of the blood, is so far similar in effect, that in either case the cause of death is to be attributed to default of the circulation. When asphyxia or suffocation is the primary difficulty, and the blood is consequently not aërated on account of the inaction of the lungs, whose special function it is to breathe in the air, the heart continuing its movement sends an impure fluid to the brain which acts as a direct poison upon that organ, and, putting a stop to its functions, terminates life. When the action of the heart is first destroyed, as it may be by wounds, ruptures, disease, or the nervous effect of mental emotions, joy, grief, anger, or fear, the brain ceases to live at once, from being deprived of blood in consequence of the inability of the heart to send a supply, and sudden death is the result. When death begins by the lungs or by the heart, the fatal termination is more rapid than when it begins at the brain. The last is the centre of the animal, while the other two are the chief instruments in the maintenance of the organic functions; and it is well known that the animal life cannot exist for a moment after the death of the organic, although the vitality of the latter is possible for a greater or less time after the cessation of the former. When, therefore, the action of the brain is first arrested by disease or violence, and the animal functions of sensation, thought, and motion cease, the organic functions of respiration and circulation may still continue. For example, in apoplexy, a disease of the brain, the individual falls senseless and motionless, but his lungs continue to operate and his heart to beat. These organs, however, are affected from the beginning, and act with diminishing power, until they cease entirely, and death is the result.—*Facies Hippocratica* is the term applied to the ordinary appearance of the dead human countenance, from the generally truthful description given by Hippocrates, whose words have been thus translated: "The forehead wrinkled and dry; the eye sunken; the nose pointed and bordered with a violet or black circle; the temples sunken, hollow, and retired; the ears sticking up; the lips hanging down; the cheeks sunken; the chin wrinkled and hard; the color of the skin leaden or violet; the hairs of the nose and eyelashes sprinkled with a yellowish white dust." Some of these appearances, however, show themselves previous to death, and in diseases that do not necessarily terminate fatally, while many of them are entirely absent in those who die suddenly, or of ailments not long protracted or very painful. It becomes therefore a matter of great importance to decide whether there are precise indications of death, and what they may be; such undoubtedly exist, in spite of the vulgar notion of their frequent absence. There are but few well authenticated cases of premature burial, and these were probably from design or barbarous ignorance. The horror of being buried alive naturally, however, so excites the imagination, that it is prepared to receive the most marvellous fables as if they were authentic facts. A French writer named Fontenelle has, in his work on the signs of death, given full scope to his credulity, and accepts without hesitation the most absurd stories of persons being buried alive. He narrates, with a faith more marvellous than are even the extraordinary incidents of some of his recitals, 100 cases of premature burial gathered from all the world and from all history, and which he would have us believe are truths, but he gives no evidence of their genuineness. Louis, a French writer on medical jurisprudence, relates that a patient who was supposed to have died at the hospital was removed to the dissecting room. Next day Louis was told that moans had been heard, and on repairing to the place he was persuaded, as the winding sheet was more or less disturbed, that the supposed dead had revived during the night, and had died subsequently. The moans heard and the disarrangement of the coverings of the dead, in this case, were however no proofs of the movements of life, and it is quite possible that Louis was misled by indications that have often seemed to give sanction to the popular notion of persons having revived after apparent death. Bodies are often found turned in their coffins and their grave clothes disarranged. These effects are however easily explained without any supposition of life by the fact that the gases generated by corruption imitate in their action upon an inanimate body some of the movements of vitality. Dead bodies which have been long in water, when not secured to the dissecting table, have been known to be heaved up and thrown to the ground from the mere effect of the gases developed within them in the progress of corruption. This is in fact a constant effect in bodies that have been interred, and undoubtedly the supposed moans sometimes heard, the changes of position observed, and the horrible idea entertained of the flesh being gnawed in hunger, may be accounted for by the generation of the gases after death, which will explode with a noise, twist the body, and break through the integuments. There are certain indications which in the aggregate are such sure proofs of death that none but the ignorant can be in doubt. These are mainly cessation of breathing, stoppage of the heart, coldness and paleness of the surface, a film on the eye, rigidity of the joints with subsequent flexibility, loss of contractility of the muscles under the stimulus of galvanism, and the beginning of corruption, which first shows itself in a dark greenish color about the skin of the abdomen. For a long time both science and popular belief considered the mirror and the feather as the critical tests of death. These were held to the mouth of the supposed dead, and if the surface of the one remained undimmed, and the "light and weightless down" of the other unmoved, all hope of life was extinguished. The surest proof, however, of the cessation of breath, is the cessation of the movement of the chest and abdomen, which will continue to rise and fall as long as the least respiration re-

mains.—Lord Bacon says: "It is as natural to die as to be born; and to a little infant, perhaps, one is as painful as the other." The imagination naturally shrouds the great mystery of death with a solemnity so great that none contemplate its approach without awe, and few without terror. By a natural association in the common mind of fear with suffering, the act of dying has been commonly supposed to be painful. So general is this belief that the term "agony," or the expressions the "pangs of death" and "last struggle," are almost universally applied to the termination of life, as if it necessarily involved violence and suffering. "Certainly," as Bacon says in his essay on death, "the contemplation of death, as the wages of sin and passage to another world, is holy and religious; but the fear of it, as a tribute due unto nature, is weak." So exaggerated have been the notions of the pain of the last moments of life, that it was long considered an act of humanity to anticipate nature by violence. For ages it was the custom in Europe to remove with a sudden jerk the pillow from the head of the dying, in order to hasten death and thus prevent the supposed agony of the last struggle. However painful the mortal disease, there is every reason to believe that the moment preceding death is one of calmness and freedom from pain. As life approaches extinction, insensibility supervenes—a numbness and disposition to repose, which do not admit of the idea of suffering. Even in those cases where the activity of the mind remains to the last, and where nervous sensibility would seem to continue, it is surprising how often there has been observed a state of happy feeling on the approach of death. "If I had strength enough to hold a pen, I would write how easy and delightful it is to die," were the words of the celebrated William Hunter during his last moments. "If this be dying, it is a pleasant thing to die," has been uttered in the enthusiasm of many a dying person; and Louis XIV. is recorded to have exclaimed with his last breath: "I thought dying had been more difficult." Those who have been snatched from the very jaws of death, and have lived to record their sensations, have almost unanimously stated that the apparent approach of the last moment was accompanied by not only a sense of ease but a feeling of positive happiness. Montaigne in one of his essays describes an accident which left him so senseless that he was taken up for dead. On being restored, however, he says: "Methought my life only hung upon my lips; and I shut my eyes to help to thrust it out, and took a pleasure in languishing and letting myself go." The pain in the case of Montaigne, and in that of others similarly restored, seems not to have been in the apparent progress to death, but in the return to life. Cowper, when restored from his mad attempt at suicide by hanging, said on reviving that he thought he was in hell. With the restoration of vigor there comes a renewal of sensibility and a consequent power of suffering, which are extinguished in the paralysis of approaching death.—Of all deaths called violent, perhaps those by some of the poisons are the easiest, such as prussic acid and opium, which act directly on the nervous system, first lulling it into repose, and finally sinking it into the insensibility of death. Drowning has been generally supposed to be a painful mode of terminating life. This, however, would seem to be an error, which probably has become common in consequence of the first struggles made by a drowning person, from fear. Captain Burney, the brother of the famous novelist Madame d'Arblay, who had a remarkable recovery from drowning, has, in a description which he has left of his sensations while under water, declared that they were totally free from pain. Another has recorded that his feelings were not only of comfort, but of such luxurious delight as he groped on the bottom of the stream, that he felt quite indignant at those who pulled him out. A writer in the "Quarterly Review" records that a gentleman who had been rescued from drowning declared that he had not experienced the slightest feeling of suffocation. "The stream was transparent, the day brilliant, and as he stood upright he could see the sun shining through the water, with a dreamy consciousness that his eyes were about to be closed on it for ever. Yet he neither feared his fate nor wished to avert it. A sleepy sensation which soothed and gratified him made a luxurious bed of a watery grave." A person drowning is soon deprived of air, and the heart supplies, instead of arterial, venous blood, which acts upon the brain like an opiate, and deadens its sensibility. Sudden death by a gun-shot wound is also supposed to be easy; and accordingly the practice, which has been carried out so frequently during the Indian mutiny, of shooting the rebellious sepoys from the cannon's mouth, is not so severe in pain to the suffering victims as it appears horrible to the terrified beholder. The first effect of a fatal shot would appear to be benumbing to the sensibility; and where, after the mortal wound, there has been a momentary interval of life, it has been frequently observed that the mind is occupied, not with a sense of suffering, but with its habitual thought and feeling. The first act of Charles XII. of Sweden, on receiving a ball in his brain, was to grasp his sword. In death by cold, it is only in the preliminary stage where there can be much suffering, for the first evidence of danger is a state of drowsiness and stupor which is entirely incompatible with pain. Dr. Solander, who accompanied Cook and subsequently Sir Joseph Banks on their expeditions, was so conscious of the dangerous symptom of sleep, in those exposed to excessive cold, that he warned all against it; and at the same time he himself was so bewitched by its influence as to be among the first to lie down in the snow to enjoy the fatal slumber. He was, however, fortunately aroused in spite of himself by his companions, who had benefited by his emphatic lessons proper for the emergency. So-

lander's servant did as his master did and not as he said, and when aroused, with the warning that he would die if he slept, answered that that was all he desired. Similar expressions are recorded by all travellers in the arctic regions, and Napoleon's fatal retreat from Moscow was marked at every step by those who, benumbed with cold, lay down only to sleep, but never awoke again to life.—Justice, which has always claimed to be heaven-born, has more often shown, at least in past times, a lower affinity. When the torture, the quartering, and the burning of living criminals were the manifestations of the execution of law, cruelty succeeded in giving extreme horror and suffering to death. As late as the 16th century, the medical school at Montpellier received its annual tribute of a criminal to be dissected alive, for the benefit of science. Ravaillac, the assassin of Henry IV., was torn limb from limb by horses, while yet alive, and during the agony his flesh was pulled away in bits by red-hot pincers, and boiling oil poured upon the raw wounds. As late even as the time of Louis XV., Damiens met with a fate similar to that of Ravaillac. Even in England, in the reign of Queen Elizabeth, traitors were disembowelled during life; and in the time of her father, Henry VIII., boiling to death was an occasional punishment. It was only within the last century that in Great Britain justice, in dealing with treason, so far tempered punishment with mercy as to spare the traitor the agonies of a cruel and lingering death. In all civilized countries, while capital punishment has been retained for certain crimes, ingenuity has been exercised to render death as speedy and as little painful as possible. Loss of life, without any added horror, is supposed to be sufficiently effective for the ends of justice. Hanging is the mode of capital punishment practised in the United States and in England. The guillotine is the instrument used in France, and the garotte in Spain. The cause of death, in hanging, is ordinarily suffocation from the tightening of the rope about the windpipe. Occasionally, however, the neck is dislocated, although rarely, unless the executioner should give a sudden twist to the body when he swings off his victim, or a kinsman with a merciful intent, as in some countries was once allowed, should spring with his full weight upon his suspended relative. Hanging is not supposed to be a painful mode of terminating life. Those who have lived to record their sensations, after hanging by the neck until they became insensible and on the very verge of death, declare that at first there was but a brief period of discomfort, which at once gave way to delightful sensations of varied lights and colors and charming visions. "A criminal, who escaped," says a writer in the "Quarterly Review," "by the breaking of the cord, said that after a second of suffering, a fire appeared, and across it the most beautiful avenue of trees. Henry IV. of France sent his physician to question him, and when mention was made of a pardon, the man answered coldly that it was not worth the asking." The Spanish garotte is composed of a metallic collar with a screw by which it is tightened about the neck of the criminal; its effects and the sensations produced must be similar to those of hanging. The guillotine, which was brought into operation in France at the suggestion of a Dr. Guillotin, can hardly be called an improvement upon the gallows. There is undoubtedly more suffering from the cutting effects of the falling blade of the instrument; but after the head is severed, although its eyes and lips may move and the muscles of the body contract, there is, notwithstanding some have argued the contrary, an end to all sensibility to pain. Probably crucifixion, with its cruel nails, its torturing strains, and its lingering agonies, is the most painful punishment ever invented by the ingenuity of cruelty. Travellers now and then record the existence of the most horrible tortures practised by barbarous nations on their criminals and captives. —We conclude the subject with that remarkable passage from Montaigne, from which the wise Bacon has borrowed a sentence, and the eloquent Taylor a noble passage. Montaigne says: "I have often considered with myself whence it should proceed that in war the image of death, whether we look upon it as to our own particular danger or that of another, should without comparison appear less dreadful than at home in our own houses (for if it were not so, it would be an army of whining milksops); and that being still in all places the same, there should be, notwithstanding, much more assurance in peasants and the meaner sort of people than in others of better quality and education; and I do verily believe that it is those terrible ceremonies and preparations wherewith we set it out that more terrify us than the thing itself. An entirely new way of living, the cries of mothers, wives, and children, the visits of astonished and afflicted friends, the attendance of pale and blubbering servants, a dark room set round with burning tapers, our beds environed with physicians and divines, in short, nothing but ghostliness and horror round about us, render it so formidable that a man almost fancies himself dead and buried already. Children are afraid even of those they love best and are best acquainted with, when disguised in a visor, and so are we: the visor must be removed as well from things as persons; which being taken away, we shall find nothing underneath but the very same death that a mean servant or a poor chambermaid died a day or two ago, without any manner of apprehension or concern. Happy, therefore, is the death that deprives us of the leisure for such grand preparations."

DEATH-WATCH, a small beetle, of the family *serricornes*, and genus *anobium* (Fabr.). The body is of a firm consistence, short, and ovoid in shape; the rounded head is almost entirely received into an arched thorax; the antennæ are terminated by 3 joints larger than the rest, the last being ovate; the mandibles are

short, thick, and dentated beneath the point; the palpi are very short, and end in a large ovoid joint; the tibiæ are not dentated, and the terminal spurs are very small. They are slow in their motions, rarely fly, and when touched counterfeit death for a long time; hence their generic name, from *αναβιον*, resuscitated. Olivier states that they will allow themselves to be pulled to pieces, and even slowly burned to death, without showing the least sign of life. The larvæ resemble white soft worms, with 6 short feet; the scaly head is armed with two powerful cutting maxillæ, with which they gnaw into wood, old furniture, books, &c., leaving behind them small round holes like those of a gimlet, whence the French name *vrillettes;* their excrements form the small masses of worm-eaten wood often seen on the floors of old and deserted houses; the larvæ also attack the flour of various grains, wafers, prepared birds and insects, concealing themselves in grooves or galleries; they pass the nymph state in their cells lined with a few silken threads. The tick of the death-watch is made by the perfect insects, of several species, by striking with their heads or mandibles against the wood in which they are concealed; these strong and repeated strokes, from 7 to 11, resemble the regular ticking of a watch, and are supposed to be the means by which the sexes call each other. There are 10 species enumerated by Mr. Stephens in Great Britain alone, which make this much dreaded sound. One of the most common is the *A. striatum*, with striated wing covers, considered by some the same as the *A. pertinax* (Fabr.), of a dark brown color; another is the *A. tessellatum* (Fabr.), with the wing covers handsomely tessellated. The tick resembles that made by tapping the finger-nail gently on the table, so much so that the insect hearing it may often be led to recommence its sounds. The superstitious regard this sound with fear, firmly believing that

> The solemn death-watch clicks the hour of death.

Such firm hold had this belief in Sir Thomas Browne's time, that, says he, "the man who could eradicate this error from the minds of the people would save from many a cold sweat the meticulous heads of nurses and grandmothers." The wood louse, a neuropterous insect, of the tribe *termitinæ*, and genus *psocus* (Latr.), makes a similar tick. The *P. pulsatorius* (Linn.) is very small, soft, white, and slender, with a reddish mouth; it lives in old wood and books, wall paper, collections of insects and plants, &c.; it is quick in its motions, darting into dark corners; the ticking noise is made by striking the wood with its head, and probably for the same purpose as in *anobium*.

DE BAY. See Baius.

DEBENTURE (Lat. *debere*, to owe), the drawback or right allowed to merchants of claiming repayment or remission of duties on imported goods when the goods are reëxported. The term is also used for the custom house certificate which is issued as a voucher for such right. Goods may be entered subject to debenture, in which case the original invoice is left with the collector; but without such entry at the time of importation, the drawback may be obtained upon reëxportation by making satisfactory proof of the identity of the goods. It is required that they be exported in the original packages, casks, &c., and when any change of such packages may become necessary, it must be made under the inspection of a revenue officer. A drawback of duties on wines and spirits is not allowed unless such liquors have been deposited in public stores, and kept there from the time of landing until re-shipment. Three years from the time of importation is allowed for reëxportation with drawback of duties, but such exportation must be from the district of original importation. The general regulations of debenture are contained in the act of congress of March 2, 1799, but modifications have been made by various other acts.

DE BOW, James Dunwoody Brownson, an American journalist and statistician, born in Charleston, S. C., July 10, 1820. His father, Garrett De Bow, was long a merchant in Charleston, and the son was for 7 years employed in a mercantile house in that city. But, as he manifested an inclination for intellectual pursuits, his father determined to afford him full opportunity for acquiring a liberal education, and he was graduated at Charleston college in 1843. He next studied law, and was admitted to the Charleston bar in 1844. Owing to his fondness for literature and statistics, he made little effort to practise his profession, but became a contributor to the "Southern Quarterly Review," published at Charleston, and in 1844 he took charge of that periodical as chief editor. Among other papers prepared by him for its pages was an elaborate article, published in 1845, upon "Oregon and the Oregon Question," which attracted much attention both in this country and Europe. It was translated into French, and was the occasion of a debate in the French chamber of deputies. In the latter part of 1845 he withdrew from the "Southern Quarterly," removed to New Orleans, and established "De Bow's Commercial Review." This enterprise proved successful, and the work attained a circulation greater than has ever been reached by any similar publication in the South. In 1848 Mr. De Bow was elected professor of political economy and commercial statistics in the university of Louisiana. This position he held but a short time, when he was placed at the head of the census bureau of Louisiana. He held this office for 3 years, during which he collected and published a great mass of valuable statistics in reference to the population, commerce, and products of that state. In March, 1853, he was appointed by President Pierce to the office of superintendent of the U. S. census. In that position he collected and prepared for the press a large part of the material for the quarto edition of the census of 1850. He afterward compiled the 8vo.

volume entitled "Statistical View of the United States," being a compendium of the 7th census. Of this work 150,000 copies were printed by order of congress. In 1853 he compiled from his review a work in 3 vols. 8vo., which he published under the title of "Industrial Resources of the Southwest." During Mr. De Bow's official career he continued to edit his review. The business connected with the census of 1850 was completed in 1855, and the bureau was discontinued. Since that time he has devoted his time to the review, lecturing, and other literary pursuits. He has taken an active part in the various enterprises tending to the advancement of the material and intellectual interests of the South. He has been a member of nearly every southern commercial convention since that at Memphis in 1845, over which the late John C. Calhoun presided. He was president of the convention at Knoxville, Tenn., in 1857. He has contributed many articles upon American topics to the new edition of the "Encyclopædia Britannica," has delivered various addresses before literary, agricultural, and other associations, and was one of the founders of the historical society of Louisiana, which has since been merged in the academy of science.

DEBRECZIN (Hung. *Debreczen*), after Pesth the largest and most important commercial town of Hungary, capital of the county of North Bihar, in the district of Gross-Wardein (according to the late division—previously Circle beyond the Theiss), is situated in an apparently boundless sandy but fertile plain, in the N. E. part of the Hungarian Lowland (Alföld), about 130 m. E. from Pesth; lat. 47° 32′ N., long. 21° 36′ E.; pop. about 60,000. It is an open town with long suburbs ending on a vast heath, and has a rustic appearance from its mostly one story thatched houses, with large yards, but contains also a number of fine buildings, of which the principal are the town house, several churches, the Piarist monastery, and the Protestant reformed college, founded in 1792. The last mentioned possesses a large library and other valuable collections, and is now the best frequented seat of learning for the Calvinist youth of Hungary. There are several other higher educational institutions belonging to both Protestants and Catholics, as well as a number of charitable establishments and a house of correction. The principal streets, in which a few years ago side planks still served to lead the passengers through the deep mud in winter and the dusty sand in summer, have lately been paved with brick. The inhabitants, who with the exception of a few thousands belong to the Protestant religion, are robust, hardy, and patriotic Magyars, and are regarded as the very types of the rural portion of their race. They are mostly agriculturists, and many of them retire several times in the year with their families and cattle to their distant fields on the plain, where they live for weeks in huts or under tents, performing the necessary labors. A numerous class is engaged in the manufacture of coarse woollens, sheepskins for clothing, leather, shoes and boots, saltpetre, soap, various kinds of pottery, cutlery, cooperage, combs, buttons, pearl wreaths, and particularly clay tobacco pipes, of which several millions are produced annually. The trade of Debreczin is equally important, consisting chiefly in cattle, horses, swine, hides, bacon, potash, wine, various kinds of oils, cheese, and Vienna haberdashery and colonial articles, for which it is the chief depot for eastern Hungary and Transylvania. Its 4 annual fairs are held on the surrounding plain, an immense space of which is then covered with tents and huts, herds and wagons, bales and cases, and thousands of people from all parts of the country and the adjoining provinces. Numerous railway lines, which are now in course of completion, will soon connect Debreczin with all parts of the Austrian empire. The bread of Debreczin is renowned, but the town suffers from scarcity of water.—During the long wars between the Hapsburg monarchs of Hungary, the Turks, and the princes of Transylvania, Debreczin was often taken, pillaged, and partly destroyed. The Turks finally left it in 1684. Having embraced Protestantism in the first half of the 16th century, and adopted the Helvetian creed in a synod held there in 1567, it suffered bloody persecutions, in 1686, from the Austrian general Caraffa. It also suffered greatly during the insurrection under Rákóczy, after the termination of which it was made a free royal town in 1715. In the earlier part of 1849 it was the seat of the Hungarian revolutionary government under Kossuth, and the sessions of the diet were held there from Jan. 9 to May 30, in the most important of which, held in the Calvinist church, on April 14, the independence of Hungary was declared. On Aug. 2 the flank guard of Görgey, under Gen. Nagy-Sándor, was surprised by an overwhelming Russian force on the plain before the town, and was dispersed after a short though lively resistance.

DEBTOR AND CREDITOR. In the early laws of every country there will be found greater severity against debtors than there is at a later period of civilization. The reason is twofold: 1, the want of sufficient intellectual acumen to distinguish the degrees of wrong in cases of fraud and of unforeseen accident and misfortune; 2, the actual want of probity in the earlier period of national existence. There is undoubtedly a prevalent error in respect to the latter consideration. It is very common to suppose that in a rude state of society there is a greater degree of honesty and fair dealing than in an advanced civilization. But that this is a mistake we need no better proof than the history of the laws of the Germanic nations. There was no lack of personal independence, at least of intrepidity in war, yet in judicial proceedings it was found that no reliance whatever could be placed upon the oaths of parties or witnesses. Thus, instead of producing witnesses who could testify to the fact in question, numerous compurgators or conjurators were called to swear that

they believed the statement made by the party who called them; and even this was found so uncertain that the trial by combat was preferred by the men of that period, as a better mode of determining the fact. So it is reasonable to infer by analogy that the cruelty exhibited in the early laws of the Athenians, and in the Roman law of the 12 tables, was founded upon the trickery and dishonesty which prevailed at Athens and Rome. It was, however, a barbarism to involve the innocent as well as the guilty in an undiscriminating condemnation. The right of the creditor to sell the debtor as a slave was abolished by Solon. The decemvirs of Rome, who professed to follow his legislation, did not conform to it in this particular, but enacted a law more oppressive than the Athenian, or indeed than any other law of which we have an authentic record, whereby the debtor was subject to be taken by the creditor to his own house, and to be dealt with in the most cruel manner for 60 days, after which he could be sold into foreign slavery. The atrocious conduct of a usurer who undertook to gratify his lust upon a young man who had surrendered himself for a debt of his father, and in consequence of the resistance of the prisoner to his attempt, scourged and otherwise maltreated him, led to an outbreak of the people and the passage of a law by the senate, A. U. C. 428, by which creditors were prohibited from taking debtors into their own custody, but the right of selling them into slavery still remained. This power of the creditor over the debtor seems to have become practically obsolete, and a milder mode of treatment grew up, under the emperors. According to the Institutes of Justinian, a debtor was subject only to loss of property for payment of his debts. The same practice prevailed in England at an early period. Suits were commenced by a summons, and if the defendant failed to appear, process was issued for the attachment of his property; but in actions upon contract no further remedy was given, either at the commencement of the suit or after judgment. In actions for injuries accompanied with force, it was, however, permitted to issue process for the arrest of the person. By various statutes the same remedy was extended to other actions in which there was no force, as actions of account, debt, detinue, and actions on the case. In the court of king's bench, however, the defendant was, without the aid of these statutes, liable to arrest upon process issued for an alleged trespass, and when arrested he was made to answer for any other cause of action. In the court of exchequer jurisdiction was obtained by a similar fiction. Upon recovery of judgment in any action in which an arrest was allowed upon mesne process, a writ could be issued called a *capias ad satisfaciendum*, whereby the defendant could be arrested and committed to close custody (*in arcta custodia*); in which respect the proceeding was more rigid than it was upon mesne process, for in the latter the defendant could be discharged upon giving bail for his appearance, whereas upon final process he could not be allowed to be at large; and if he was suffered by the sheriff to be outside of the gaol, it was deemed an escape, for which he was made liable for the whole amount of the debt. In the United States the same forms of proceeding were introduced, but were gradually modified in advance of the changes which were made in the English practice, which will be presently adverted to. Thus, in the state of New York it was provided that a *capias ad satisfaciendum* should not be issued till after an execution against the property (called a *fieri facias*) had been first issued and returned unsatisfied. In 1831 imprisonment for debt upon contract, except in certain cases, was abolished in that state. The excepted cases were where fraud had been committed or was intended, in which cases an arrest could be ordered by a judge, to which exception was added, by statute of 1846, the case of money received in a fiduciary capacity; and by a subsequent statute imprisonment for interlocutory costs was abolished. The principle embraced in these laws was adopted in the code of procedure of 1849. Arrest is thereby prohibited in all civil actions, except in certain specified cases, viz.: in actions for injury to the person or character, or for injuring or wrongfully taking or detaining property; in cases of embezzlement by public officers, or persons acting in a private fiduciary capacity; for misconduct in office or any professional employment; in actions to recover the possession of personal property where it is concealed or kept out of the reach of the sheriff; and in cases where the defendant has been guilty of a fraud in contracting the debt or in avoiding the payment of it. In the excepted cases there may be an arrest by an order of a judge, in which order the amount for which the defendant shall be held to bail is specified; and when there has been arrest upon mesne process the like remedy in all cases is given upon final process. No provision is made by the code for a discharge from an arrest under such order. Females are exempted from arrest in all cases except actions for wilful injury to person, character, or property. The legislation of the state of New York has been followed in several other states, and may be assumed in its general features as the prevalent system throughout the United States, in respect to the coercive remedy for the collection of debts by process against the person.—In England important modifications have been recently made in the laws relating to the collection of debts. In 1838 (by stat. 1 and 2 Victoria, c. 110), arrest upon mesne process for debts exceeding £20 was abolished, except in cases where proof was made of the intention of the defendant to leave England. Provision was also made for discharge from liability to imprisonment upon final process, upon the surrender by the debtor of all his property for the payment of his debts. In 1842 (by stat. 5 and 6 Victoria, c. 116), similar provision was made for discharge from imprisonment for debts under £20; and in 1844 (7 and 8 Victoria, c. 96),

arrest upon final process in an action for a debt not exceeding £20 was abolished, except where there was fraud in the contracting of the debt, or a fraudulent attempt to avoid payment, leaving it to the discretion of a judge to order an arrest upon proof of any such fraud. A great amelioration was effected by these statutes. The relief under the previously existing bankrupt laws applied only to a class designated as traders, leaving a large proportion of debtors entirely unprovided for; and the relief itself, even in cases to which it was applicable, was harsh to the debtor, wasteful of the assets devoted to the creditors, and not unfrequently all beneficial effect was defeated by the technical stringency of the statutes, and the extreme severity of the courts. (See BANKRUPT.) Then as to the relief of insolvents, under the act of 32 George II., c. 28 (commonly called the lords act, from the circumstance of its having originated in the house of lords), it was limited to debtors actually in custody upon execution for debts under £100 (afterward extended to £300); and notwithstanding the surrender of the debtor's property as provided by the act, the creditor could still if he chose detain the debtor in prison, subject only to the condition that he was to allow 2*s.* 4*d.* per week for his support.—The insolvent laws of the state of New York are of a twofold character. By one mode of proceeding, the debtor obtains a discharge from imprisonment on account of debts upon the surrender of his property, the application for this purpose being made by the debtor upon notice to all his creditors; by another mode of proceeding, upon the application of the debtor in concurrence with creditors to the amount of two-thirds of the entire indebtment, he obtains a discharge from all future obligation on account of his debts, or in other words, from the obligation of his debts. In both these cases the discharge is withheld when the debtor, knowing his insolvency, has made disposition of any part of his property with the view of giving a preference to one creditor over others. The practical effect of this provision has been to restrict the benefit of the statute within too narrow limits, as there are few cases where a discharge could be obtained if the restriction should be rigidly enforced. In the struggle to avoid a failure, peculiar obligations are to a greater or less extent almost always incurred, which have a claim upon the debtor superior to that of his ordinary indebtment, although in law all are placed upon the same footing. Preferences will accordingly be given by the debtor in such cases, even at the peril of having to depend upon the gratuitous consent of the rest of his creditors for release from his debts. Individual hardship will thus sometimes occur, but generally relief can be had by compromise with the creditors upon fair terms when the case is free from fraud. Greater liberality in this respect is perhaps to be found in this country than in any other. In both of these insolvent proceedings, the discharge is only from debts upon contract; yet a judgment for a cause of action arising *ex delicto* is deemed to have merged the original nature of the debt, and is included. A 3d form of insolvent proceedings is where the debtor is in custody upon execution, in which case he may obtain a discharge in the particular suit by a surrender of his property, without being precluded by having given preferences in payment of debts; nor is it prescribed by statute that the judgment upon which such execution has issued must have been recovered upon contract. It has now no other value except as it may be available for a discharge in actions for tort and other cases in which arrest is still allowed by the code. A similar insolvent procedure has been adopted in most of the states, so far as respects relief from imprisonment, but the experiment made in the state of New York of releasing the obligation of debts has not been generally acted upon in other states. An interesting question in respect to the validity of insolvent laws of the latter description has been brought into discussion in the U. S. courts, under the provision of the federal constitution prohibiting the passage of a state law impairing the obligation of contracts (Constitution, art. 1, § 10), and the following propositions have been settled: 1, that an insolvent law is inoperative to discharge a debt existing at the time of the passage of the law; 2, that it has no validity for the discharge of debts due to citizens of other states, or rather that such discharge is no bar to an action brought by citizens of other states for the recovery of such debts in the courts of the United States, or of any other state than that where the insolvent discharge was granted; 3, that the validity of such discharge is not sustained by the fact that the contract was made in the state where it is discharged, as against citizens of other states; 4, that in the courts of the state whose insolvent law is in question, as between citizens of such state, it is not to be held a law impairing the obligation of contracts, and a discharge under it may be properly held valid; 5, that a citizen of another state who sues in the courts of the state where the discharge is granted, is subject to the same rule as a citizen of such state. (Ogden *vs.* Saunders, 12 Wheat. 213; Boyle *vs.* Zacharie, 6 Peters, 648.) The last proposition was not necessarily involved in the decision of either of the above cited cases, and seems scarcely consistent with the harmony of the courts of the different states and of the United States. Another proposition was left untouched, viz.: what is the rule where the question is between parties who were both citizens of the state where such an insolvent law exists, and the contract was made in such state, but the creditor has become a citizen of another state and sues in the courts of the United States or of such other state. Two principles combine to make the discharge valid, viz.: the *lex loci contractus*, and the subjection or supposed consent of both parties to the law of the state of which they were citizens. The former was

repudiated by the supreme court in the cases above cited, but the latter was maintained and much insisted upon as the basis upon which alone the law of the state could be held not to impair the obligation of contracts.—By the laws of most countries of Europe, the cession of the property of an insolvent to his creditors for the payment of debts is not a ground for releasing his future acquisitions from liability for his debts, but only for discharging the debtor from process against his person. In France, the law respecting imprisonment (*contrainte par corps*) for debt has recently undergone great modification. For commercial debts, imprisonment is limited to 3 months when the amount does not exceed 500 francs, 6 months when the amount does not exceed 1,000 francs, and so on in that proportion, but not to extend beyond 3 years for any amount; and in the case of a man having minor children, imprisonment may be suspended a year. Ecclesiastics, minors, septuagenarians, and women not engaged in commerce, are exempt from imprisonment. Officers of courts (*greffiers*, *notaires*, *avoués*, *huissiers*, &c.) are subject to *contrainte par corps* for moneys received by them officially or professionally, and wrongfully withheld, or for any other violation of official or professional obligation to suitors. So also constraint is allowed *pour stellionat*, *i. e.* the selling or hypothecating property belonging to another, *en cas de redintegrande*, or action for the recovery of property wrongfully withheld, and various cases of fraud or breach of trust. The law relating to this subject is to be found in the *Code civile*, § 2,060 *et suivans; loi* 27 *Avril*, 1832; and *loi* 13 *Dec.* 1848.

DECADE (Gr. δεκα, ten), an aggregate of ten. In the French republican calendar, decades of days were substituted for weeks in the division of the year. In the French system of weights and measures, the prefix *deca* multiplies the quantity by 10, while *deci* divides by 10.

DECALOGUE (Gr. δεκα, ten, and λογος, word), the Ten Commandments, or more properly, according to the Hebrew, the Septuagint, and Vulgate, the ten words or sayings which God delivered to the Jews through Moses. They contain the fundamental precepts of religion and morality, and are almost universally regarded as the golden rules for every society, age, and people. The division of the commandments has elicited a manifold difference of opinion. Of the various modes of dividing them which have found both numerous and weighty defenders, the following may be regarded as historically the most important: the Origenian or Philonic, the common Jewish or Talmudic, and the two Masoretic. According to the 1st, which is supported by the Jewish testimony of Philo and Josephus, and the authority of Origen, Gregory Nazianzen, and Jerome, the 1st precept consists mainly in the words: "Thou shalt have no other gods but me;" the 2d forbids images of God; the 3d forbids taking the name of God in vain; the 4th commands the sanctification of the sabbath day; the 5th, to honor one's father and mother; the 6th forbids murder; the 7th, adultery; the 8th, theft; the 9th, bearing false witness; and the 10th, concupiscence. This division has been adopted by the Helvetian and Anglican churches, by the Lutherans of the school of Bucer, and by the Socinians. The Talmudic division, which is also that of the modern Jews, being supported among other authorities by Maimonides's "Book of the Commandments," and Aben Ezra's commentary on the Pentateuch, differs from the preceding only in making the words, "I am the Lord thy God, who brought thee out of the land of Egypt, out of the house of bondage," the 1st commandment, and in considering the prohibition of the worship of other gods and of images as the 2d. This division is proved by a quotation from Julian in Cyril of Jerusalem to have been generally known in the early centuries of the Christian era, and has through the authority of Pseudo-Athanasius also been adopted by the Greek churches, including the Russian, which has sanctioned it in its catechism. The Masoretic division, in both forms, so called on account of its being based on the Hebrew text as revised according to the rule of the Masora, unites the passage on the exclusive worship of God with the prohibition of images to make the 1st commandment, and restores the number 10, which is distinctly specified in the Scriptures, by dividing the last into 2; the text of Exodus separating by the mark of division (ס) the prohibited coveting of a neighbor's house, as the 9th commandment, from the prohibited coveting of all other objects as the 10th, while the text of Deuteronomy separates and gives first the commandment against coveting another's wife. The division according to Exodus has been adopted by the Lutheran church, and also by the council of Trent; the other Masoretic form, which is supported by the Septuagint, by St. Augustine, Bede, and Peter Lombard. The question, how many of the ten commandments were engraved on each of the stone tables of Moses, has been agitated, mostly on philosophical grounds. Philo, and after him Irenæus, are for 2 pentads; others believe the commandments on worship alone to have been engraved on the 1st table, which is regarded by some as the more divine of the two.

DECAMPS, Alexandre Gabriel, a French painter, born in Paris in 1803. In early life he visited Turkey, and afterward executed a great number of pictures of oriental scenery and characteristics. He has gained a high reputation by these works, as well as by his pictures of animals. Among the latter are many representations of apes; one of them, the "Monkey Connoisseurs," is intended as a satire on the jury of the Paris academy of painting, on account of the severe criticisms passed upon his works. One of his best historical paintings represents the "Defeat of the Cimbri." About 60 of his works figured at the great exhibition of 1855. His style of painting is bold and original, his coloring brilliant, and he is especially happy in pre-

senting strong contrasts in a humorous and picturesque manner, but has often been censured for his want of correctness.

DE CANDOLLE. See CANDOLLE.

DECAPOLIS (Gr. δεκα, ten, πολις, city,) a confederacy of eastern Palestine, which contained the following 10 cities: Damascus, Philadelphia, Raphana, Scythopolis, Gadara, Hippos, Dion, Pella, Galasa, and Canatha, and was formed by the heathen inhabitants for mutual protection against the Asmonean princes of Judæa. These cities appear to have possessed similar political institutions and privileges.

DECATUR, the name of counties in several of the United States. I. A S. W. co. of Ga., bordering on Fla., intersected by Flint river, and bounded W. by the Chattahoochee; area, about 1,062 sq. m.; pop. in 1850, 8,820, of whom 3,949 were slaves. The surface is irregular, and the soil productive. In 1850 the harvest amounted to 5,308 bales of cotton, 275,497 bushels of corn, 105,889 of sweet potatoes, and 65 hogsheads of sugar. Value of real estate in 1856, $1,379,470. The county was named in honor of Com. Stephen Decatur, jr. Capital, Bainbridge. II. A W. central co. of Tenn.; area, 325 sq. m.; pop. in 1850, 6,003, of whom 723 were slaves. The Tennessee river flows along its entire E. boundary, and Beech river intersects it. The surface is nearly level, and almost all the land is fertile. The productions in 1850 were 261,790 bushels of corn, 43,555 of oats, 66,180 lbs. of tobacco, and 52,211 of butter. There were 15 churches, and 1,058 pupils attending public schools. This county was formed in 1846 by the division of Perry county. Capital, Decaturville. III. A S. E. co. of Ind.; area, 372 sq. m.; pop. in 1850, 15,107. It is drained by several small streams. It has a level or gently undulating surface, and the soil is a rich loam, resting on a basis of limestone. Wheat and live stock are the chief articles of export. In 1850 the productions were 1,050,217 bushels of corn, 88,493 of wheat, 47,778 of oats, and 5,537 tons of hay. There were 46 churches, and 3,721 pupils attending public schools. The county was organized in 1821. Capital, Greensburg. IV. A S. co. of Iowa, bordering on Mo.; area, 528 sq. m.; pop. in 1856, 6,229. It has a rolling surface, and a good soil. A great part of the land is occupied by prairies, interspersed with numerous clusters of hard timber, scattered along the Weldon river and other streams, which intersect the county. In 1856 the productions were 13,693 bushels of wheat, 32,332 of oats, 283,249 of corn, 18,715 of potatoes, 266 tons of hay, and 63,260 lbs. of butter.

DECATUR, a prosperous village of Ga., and capital of De Kalb co.; pop. in 1850, 744. It is a handsome little town, noted for its beautiful situation and healthy climate. It is the seat of 2 seminaries. About 6 m. E. of the village is Stone mountain, an isolated granite rock, nearly 2,200 feet high, which is annually visited by thousands of persons.

DECATUR. I. STEPHEN, a commodore in the U. S. navy, born in Newport, R. I., in 1751, died in 1808, obtained the command of a vessel in the merchant service at a very early age. During the war of the revolution he commanded several privateers, and acquired some reputation by the capture of English ships. At the commencement of hostilities with France in 1798, he received the commission of captain in the navy, and was appointed to the command of the Delaware of 20 guns, in which ship he cruised during the years 1798–'99 on the American coast, and in the West Indies, capturing at different times the French privateers Le Croyable of 14, and Marsuin of 10 guns. In 1800 he commanded a squadron of 13 sail on the Guadeloupe station, the Philadelphia frigate of 38 guns being his flag ship. He was discharged from the service under the peace establishment in Oct. 1801, and engaged in commercial pursuits in Philadelphia. II. STEPHEN, jr., a commodore in the U. S. navy, son of the preceding, born at Sinnepuxent, Md., Jan. 5, 1779, killed in a duel, March 22, 1820. He entered the navy as midshipman, July, 1798, was promoted to a lieutenancy in July, 1799, and served in both grades in the frigate United States, on the West India station, under the command of Com. John Barry, during the *quasi* war with France. In May, 1801, he joined the frigate Essex, Capt. William Bainbridge, one of a squadron of 3 frigates and a brig, sent to the Mediterranean, under the command of Com. Richard Dale, in consequence of hostile demonstrations against the United States by Tripoli. War had been actually declared by Tripoli before the arrival of Com. Dale upon the station, but the orders under which he acted were prepared in ignorance of that fact, and nothing, therefore, beyond blockading Tripolitan cruisers, and the consequent protection of our commerce, was effected by this squadron, except an action which took place off Malta between the Enterprise of 12 guns, under Lieut. Sterrett, and a Tripolitan cruiser of 14 guns, which resulted in the capture of the latter. Com. Dale returned to the United States in Dec. 1801, and early in the spring of 1802 another squadron of 3 frigates, 2 sloops of war, and a brig was ordered to the same station, under Com. Valentine Morris, in which Decatur was actively employed as first lieutenant of the frigate New York, Capt. James Barron. At Malta he acted as second in a duel between Midshipman Joseph Bainbridge and an English officer, which terminated fatally to the latter. The surrender of the parties concerned to the civil authorities was demanded by the governor, Sir Alexander Ball, and it was therefore deemed prudent for Decatur to leave the squadron, and return to the United States. Com. Morris was recalled from his command in Nov. 1803, and the squadron, having been materially strengthened, was placed under the command of Com. Edward Preble, Decatur serving in it at first in command of the brig Argus of 16 guns, and subsequently of the Enterprise, 12, having been superseded in the Argus by Lieut.

Hull, his senior in rank. At the commencement of Preble's command, and in fact before he had time to appear off Tripoli himself, the frigate Philadelphia unfortunately fell into the enemy's hands; and as she added much to the defences of the port, and would doubtless be eventually sent out to cruise, it was deemed very important to recapture or destroy her. Capt. Bainbridge, then a prisoner in Tripoli, and in secret correspondence with Preble, suggested, in a letter of Dec. 5, 1803, the practicability of destroying her by fire, although she was in a harbor filled with cruisers, and surrounded by batteries. Preble was then lying at Syracuse, the rendezvous of the squadron, with the Enterprise, Lieut. Comdt. Decatur, in company. The plan was mentioned to Decatur, who at once entered upon it with great zeal and spirit. A Tripolitan mastico, bound to Constantinople with a present of female slaves for the Porte, which had been captured by the Enterprise a few days before, afforded ready means for carrying it into execution, and she was taken into the service for the purpose, and named the Intrepid. About this time Lieut. Comdt. (now Commodore) Stewart, of the brig Siren, of 16 guns, which had just arrived from a cruise, volunteered to cut out the Philadelphia; but Preble adhered to the plan already formed, and on Feb. 3, 1804, issued the order for carrying it into effect. That evening the Intrepid, convoyed by the Siren, sailed from Syracuse to execute this important service. The officers were Lieut. Comdt. Decatur, Lieuts. Lawrence, Joseph Bainbridge, and Thorn, Midshipman Thomas McDonough, and Surgeon Heerman, all of the Enterprise, and Midshipmen Izard, Morris, Laws, Davis, and Rowe, who volunteered from the Constitution, Com. Preble's flag ship, and Salvadore Catalano, a Greek, acting as pilot and interpreter. The entire crew of the Enterprise volunteered for the expedition, but only 62 of the most athletic and active were selected, making, with the officers, 74 souls. On Feb. 9 Tripoli was discovered, but bad weather prevented the attempt until the night of the 15th, when the party in the Intrepid was reënforced by Midn. Anderson and 8 men from the Siren. About 10 o'clock in the evening the Intrepid reached the mouth of the harbor. The weather was beautiful, and the sea and bay were as smooth as in summer. She entered the hostile port slowly, the breeze being very light. Decatur stood at the helm, with the interpreter beside him, the men lying on deck out of sight; a few officers only remained standing. As the frigate was neared, Decatur discovered a few of her crew looking over the hammock rail, and the Intrepid was hailed and ordered to keep off. The pilot answered, according to previous instructions, that they were from Malta, on a trading voyage, had lost their anchors in a late gale, and desired to ride by the frigate until others could be procured. The Tripolitan then asked some questions about the brig in the offing, and was told that it was the Transfer, a former British vessel of war, which had been purchased for the Tripolitans, and was daily expected to arrive. During this conversation warps were carried to the frigate, where they were received and made fast, and the crew of the Intrepid, still lying down, began to warp her gently alongside. Distrust was awakened among the Tripolitans by the discovery of the anchors of the Intrepid, and the cry of *Americanos* was raised. A vigorous pull brought the vessels in contact, the order to board was given, and Midshipman Charles Morris stood first on the quarter deck of the Philadelphia, followed immediately by Decatur. So perfect was the surprise, and so rapid and vehement the assault, that the resistance was very slight, and in less than 10 minutes Decatur was in undisturbed possession of the ship. Her foremast was wanting, and not a sail was bent, or yard crossed. To move her, therefore, was impossible, and her destruction was instantly resolved upon. The men immediately distributed themselves, according to previous instructions, with combustibles, which consisted principally of canvas sacks of dry pine and shavings, well covered with soft turpentine. All were emptied and spread in the cock pit and store rooms, and demijohns of spirits of turpentine poured down upon them from the gun deck. The ship was in a very dry state, and the conflagration so extremely rapid that the assailants escaped with difficulty. When all were on board the Intrepid, she was cast off, and for an instant was in great danger, in consequence of the fouling of a fast. It was cut, and the little vessel dropped clear just as the flames burst forth from the ports of the frigate over her deck, upon which a large mass of ammunition was lying covered with tarpaulins. The sweeps were now manned, and the Intrepid was very soon at a safe distance from the burning frigate. When a few lengths from her the men ceased to row for an instant, and gave 3 hearty cheers. A light land breeze sprung up at this critical moment, which wafted the little vessel rapidly out of the harbor. The spectacle as she left the port was described by the officers as sublime and beautiful. The bay was completely illuminated by the conflagration, and the town, castles, minarets, and mosques were all brought by it into distinct view. By the light thus afforded, a heavy fire was opened upon the Intrepid by the batteries and cruisers, though without effect, one shot only passing through a sail. The guns of the frigate, as they became heated, began to go off, and singularly enough, her broadsides bore upon the city and one of the principal batteries. The Siren was soon fallen in with in the offing, and Decatur went on board to report his success. The arrangements for this expedition were perfect. No firearms were used, but all was carried by the cutlass. Nothing was wanting, nothing defeated, and on the part of the Americans but a single casualty occurred, one man being slightly wounded. The loss sustained by the enemy could never of course be correctly ascertained. Many swam on shore,

and to the nearest cruisers, and 20 were reported to have been killed. The effect of this gallant exploit was at once to place the name of Decatur high upon the list of the most distinguished of our naval officers. Com. Preble recommended him for promotion, and a captain's commission was conferred upon him, dated on the day of the destruction of the Philadelphia; a sword was also presented him by congress, and 2 months' pay was voted to each of his officers and crew. In the subsequent attacks upon Tripoli by Com. Preble's squadron, Decatur bore a distinguished part, and especially in the one of Aug. 3, 1804. In this service a number of gun-boats and bomb vessels, borrowed from the Neapolitan government (which was at that time at war with Tripoli) were used, and in the attack referred to, Decatur commanded a division, consisting of 3 of these vessels. The special object of the attack was a flotilla of gun-boats, protected by batteries on shore, and a 10-gun brig, and there is hardly a record in naval history of an attack made with such a disparity of force and crowned with entire success. Each of the boats of Decatur's division, singling out an opponent, boarded and carried her, after a desperate hand-to-hand conflict with cutlass and pistol. Decatur, on taking possession of the boat which he first assailed, took her in tow, and bore up for the next one to leeward, which he boarded, with most of his officers and men, attacking himself the Tripolitan commanding officer the moment he attained his deck. The Tripolitan was a powerful man, of large stature, and a desperate personal struggle took place, in which Decatur fell with his antagonist upon him. With one hand Decatur grasped firmly that of his foe, who was endeavoring to reach his yatagan, while with the other he drew a pistol from his vest pocket, passed the arm around the body of the Tripolitan, and pointing the muzzle in, fired. The ball passed through the body of his foe, and killed him. In the first part of this contest between the two commanders, Decatur's life was doubtless saved by a young American sailor named Reuben James, who intercepted a blow aimed at the head of his commander, by interposing his own arm, receiving thereby a very severe wound. The desperate nature of the fighting which distinguished this remarkable assault may be inferred from the foregoing details, and the amount of loss. The 2 boats captured by Decatur had but 80 men in them, of whom 52 are known to have been killed or wounded. In another Tripolitan gun-boat, captured by Lieut. Triple, there were found living and dead 36 people, of whom 21 were killed or wounded. Three gun-boats were sunk in the harbor, in addition to the 3 which were taken; a large number of shells were thrown into the city, and the batteries were much injured. The moral effect upon the enemy of this and subsequent attacks of the same nature was very great. The superiority of the Americans in gunnery had been already admitted, and they had now overcome the Tripolitans with inferior numbers hand to hand, a species of combat in which the latter particularly excelled. In the attack of the 3d the American loss was but 14 killed and wounded. Among the killed was Lieut. James Decatur, a younger brother of Stephen, and an officer of high promise. On Aug. 7, just at the conclusion of another attack, in which Decatur participated, his commission as captain arrived from the United States in the John Adams, 28, Capt. Isaac Chauncey, and he subsequently served at one time in the Constitution as flag captain, and at another in the frigate Congress of 38 guns. On June 3, 1805, peace was proclaimed. In 1806 Decatur stood 9th on the list of captains, and between the close of the Tripolitan war and the declaration of war with England in 1812, he was variously employed, at one time superintending the construction of gun-boats. After the affair of the Chesapeake our ships of war were for the most part kept upon our own coast, in anticipation of hostilities with England, and Decatur was then in command of a squadron, the United States, 44, bearing his flag. On June 18, 1812, war with England was declared, and on Oct. 25 Decatur, still in command of the frigate United States, fell in with and captured, after an action of an hour and a half, the British frigate Macedonian, 49, commanded by Capt. John S. Carden, an officer of high reputation. She was smaller, of lighter armament, and had fewer men than the United States. She mounted long 18s upon her gun deck, and 32 lb. carronades upon her quarter deck and forecastle; while the main battery of the United States consisted of long 24s, with 32 lb. carronades upon the upper deck. But though it is admitted that the American ship was the heaviest, her superiority was certainly not in proportion to the execution done in this combat. The Macedonian being to windward could choose her distance, and the action was fought for the most part at long shot. She was very severely cut up, her mizzen mast, fore and main topmasts, and main yard being shot away, a hundred round shot in her hull, while of her 300 men 36 were killed and 68 wounded. The United States suffered but little. She lost a top-gallant mast and was otherwise somewhat cut up aloft, but her hull was very slightly injured; 7 men were killed and 5 rounded. The Macedonian was taken into New York. For this capture congress voted a gold medal to Decatur, and silver ones to each commissioned officer under his command. On May 24, 1813, Decatur sailed from New York in command of a squadron, consisting of the United States (flag ship), the Macedonian, now an American frigate, and the Hornet sloop of war. The Sandy Hook channel being blockaded by the enemy, he passed through Long Island sound, and on June 1 attempted to go to sea by running out past Montauk point. He was intercepted, however, by a British squadron of much superior force, and compelled to enter the harbor of New London, where he remained closely blockaded until the summer of 1814, when he was transferred to the

President, 44, and hoisted his pennant in that ship as commander of a squadron, consisting of 3 vessels of war and a store ship, destined for a cruise in the East India seas. So closely was New York blockaded that he did not get to sea until the middle of Jan. 1815, when he sailed at night. Unfortunately, the pilots missed the channel, and the ship struck, and beat very heavily upon the bar for an hour and a half. Upon the rising of the tide she floated, and went to sea, though obviously much injured, it being impossible to return. At daylight the next morning 4 ships were discovered in chase, one on each quarter, and two astern. The sailing of the President was so much impaired by the injuries received while on the bar, that escape was impossible, and she was brought to action about 3 P. M. by the frigate Endymion of 40 guns. A running fight took place, which lasted about 8 hours, in the course of which Decatur formed the bold plan of carrying the Endymion by boarding, and going off with her, abandoning the President to the enemy. He communicated this plan to his men, by whom it was well received, and attempted to execute it, but the superior sailing of the enemy enabled him to frustrate the efforts made to close with him. At 11 P. M. the Pomona, 38, another of the pursuing ships, also closed, and obtaining a position upon the weather bow of the President, fired a broadside into her; and as at this moment the Tenedos, 38, was fast closing upon the quarter, and the razee Majestic was within gun-shot astern, it was but too evident that further resistance was useless, and Decatur therefore surrendered, delivering his sword to the captain of the Majestic, the senior British officer present. The loss of the President during this long action was very severe; 80 were killed and wounded. Among the former were Lieuts. Babbitt, Hamilton, and Howell. Her fire upon the Endymion was principally directed at the spars, with a view to cripple her, and the loss of that ship, according to the published reports, was 11 killed and 14 wounded. The President was carried into Bermuda, and both she and the Endymion were dismasted in a gale before reaching port. Decatur was soon released on parole, and on his return to the United States was honorably acquitted by a court of inquiry for the loss of the ship. On March 2, 1815, immediately upon the termination of the war with Great Britain, congress passed an act authorizing hostilities against Algiers, that power having for some time before been engaged in depredations upon the little American commerce that remained in or near the Mediterranean. On May 21 a squadron, consisting of 3 frigates, 1 sloop of war, and 6 brigs and schooners, sailed from New York for the Mediterranean, under Decatur's command, the Guerriere, 44, being his flag ship. Mr. William Shaler was on board to act jointly with Decatur in negotiating a treaty with Algiers, should she be disposed to come to terms. On June 17, when off Cape de Gatt, on the coast of Spain, the squadron fell in with and captured the Algerine frigate Mashouda, 46, after a short running fight, in which the Algerine admiral and nearly 100 of his officers and men were killed and wounded. The prisoners amounted to 406. Two days later an Algerine brig of war, the Estido, 22, was chased into shoal water off Cape Palos by the small vessels of our squadron, and captured after a short resistance. The prizes were sent into Carthagena, and the squadron arrived off Algiers, June 28. On the 30th, just 40 days after its departure from New York, a treaty, dictated to the dey by the commissioners, was concluded. By the terms of this treaty demands upon the United States for tribute were for ever abolished. A mutual liberation of prisoners and restitution of property was made, and it was stipulated that in the event of future wars Algiers was not to treat American prisoners as slaves. As a personal favor to the dey, the captured frigate and brig were restored, though the commissioners refused to permit an article to that effect to be inserted in the treaty. Our affairs with Algiers being thus settled, Decatur proceeded with his squadron to Tunis and Tripoli, and made reclamations upon those powers for depredations committed by them upon American commerce during the war with England, obtaining prompt redress from both. As soon as this service was concluded, most of the squadron returned to the United States, and in Nov. 1815, Decatur was appointed navy commissioner, which position he held until his death. He fell in a duel fought near Bladensburg, Md., with Com. James Barron, which grew out of the affair between the Chesapeake and Leopard. Com. Barron, upon the termination of his suspension from duty, sought professional employment, in which he was warmly opposed by Decatur, and this led to his hostile meeting with that brave but unfortunate officer. Both fell at the first fire, Decatur mortally and Barron very severely wounded. No officer of the navy ever occupied a higher place in public estimation than Com. Decatur, who, among brave men, was noted as a person of the coolest and most determined courage. He was rather below the middle size, but of a remarkably symmetrical form. His complexion was dark, his eyes were black and piercing, and altogether he was a man of remarkable appearance, riveting the attention of all who saw him.

DECAZES, Élie, duke, a French statesman, born at St. Martin du Laye, Gironde, Sept. 28, 1780, filled at an early age high judicial positions, gained the confidence of Louis Bonaparte, king of Holland, whom he served even after his abdication in 1810, officiated as secretary of Letizia Bonaparte, but joined the cause of the Bourbons in 1814, and under the second restoration discharged the duties of prefect of police at Paris with marked ability. He became an intimate friend of Louis XVIII., and in 1815 a member of his cabinet as minister of police. By his conciliatory policy he gave umbrage to the ultra royalists, without giving satisfaction to the extreme

liberal party. In 1818 he became home minister, and in Nov. 1819, premier. The opposition of the royalist party broke out with renewed virulence on occasion of the assassination of the duke de Berry, in 1820, when a deputy charged him openly with being an accomplice of the murderer; and Châteaubriand, then an ultra royalist, wrote in the *Conservateur:* "His foot slipped in the blood." He then resigned, when Louis XVIII. made him a duke, and his ambassador to England, where he remained till Dec. 1821. Under the reign of Charles X. he opposed the extreme measures of the government, and after the revolution of 1830, adhered to Louis Philippe. In 1834 he was appointed grand referendary of the chamber of peers. Of late years he has devoted his activity to the superintendence of large iron works at Decazeville in Aveyron. On his marriage in 1818 with his second wife, Mlle. de Saint-Aulaire, a relative of the late duke of Holstein-Glücksburg, the title of duke of Glücksburg was conferred on him by Frederic VI. of Denmark.—His eldest son by his second wife, Louis Charles Élie Amanieu, marquis Decazes, duke of Glücksburg, born May 9, 1819, officiated previous to the revolution of 1848 as French ambassador in Spain and Portugal.

DECCAN, a country of British India, lying between the Nerbudda and Kistnah rivers. Under the Moguls the country N. of the Vindhya mountains was called Hindostan, and that lying to the S. the Deccan. Assigning it the less extended signification, it comprises nearly the whole of the Bombay presidency except Sinde; Nagpoor, Berar, Sumbulpoor, Cuttack, and part of the Saugur and Nerbudda territories, in the Bengal presidency; the Northern Circars, Guntoor excepted, in the Madras presidency; and the dominions of the Nizam, parts of those of Sindia and Holkar, and several petty native states, toward the N. E. The general aspect of this immense territory is an elevated table-land of triangular shape, supported by the mountain walls of the Ghauts on the E. and W., and by the Vindhya range on the N. The dip of the country is toward the E., all the rivers of magnitude flowing eastward to the bay of Bengal. The principal of these rivers are the Godavery, flowing E. with a course of 850 m., and the Mahanuddy, 650 m. The seaward declivity of this table-land, facing the bay of Bengal, consists of a series of terraced steeps, abrupt but not precipitous. The interior table-land mostly consists of rolling prairie. A variety of races, numbering perhaps 50,000,000 souls, differing in manners and customs, inhabit this territory. The remote history of the Deccan is lost in obscurity. An ancient division of the country into 5 kingdoms is indicated by its 5 languages. The first irruption of Mohammedans from the north took place in 1294, under Aladdin, afterward king of Delhi. He was followed by Mohammed Togluck, who, in 1325, completed the subjugation of the country. Revolts followed, and wars for 300 years, ending in distribution and re-distribution of the territory, until in 1686 it passed under the sway of the Mogul emperor Aurungzebe. After Aurungzebe's death it fell piecemeal into the hands of the Mahrattas, and was subsequently broken up into the feudal sovereignties which yet exist in name. About the middle of the last century British influence became predominant, and by conquest and annexation, especially since 1818, the greater part of the Deccan has been absorbed into the British Indian empire, and was little disturbed by the recent insurrection.

DECEMBER, the 12th month of the year, from the Latin *decem*, 10. The Roman year began with March, so that September was the 7th and December the 10th month.

DECEMVIRI (ten men), the name of the members of several Roman magistracies, distinguished by an additional denomination. The *decemviri legibus scribendis* (appointed to digest a written code of laws) were first elected in the year 451 B. C., during the long dissensions between the two orders after the establishment of the tribunate. The tribune Terentius (or Terentillus) Arsa, after a violent exhibition of the grievances of the plebeians, and the usurpations of the patricians, proposed (460) the appointment of 10 commissioners to digest a regular body of laws which should secure the rights of all, and be binding alike on consuls, senators, patricians, and plebs. This was accomplished after 9 years of continued disputes and struggles. An embassy, it is said, was sent to Greece to obtain information concerning the laws of the different states, and particularly concerning those of Solon; and after their return 10 distinguished patricians were appointed for a year, with supreme power, to frame the new laws. They commenced and continued their work with zeal and accuracy, and exercised their power with justice, impartiality, and moderation, each presiding by turns, day by day, and he only using the fasces. The new laws, engraved on 10 tables of brass, were placed in the forum and sanctioned by general acclamation, as well as by the sacred rites of the augurs. But the addition of two new tables being required, a new decemvirate was elected for the next year, in which the ambitious patrician Appius Claudius managed to be reëlected, and to introduce a few plebeian members. He thus became the favorite of the people, while aiming to become their master. The laws were completed, and afterward known under the name of "Laws of the XII. Tables," and were admired for their wisdom, which, according to Cicero, surpassed that of all the books of philosophy. But now the decemvirs changed their conduct, exercised their power over all classes of the people with oppressive rigor, and continued in office illegally after the expiration of their term, maintaining themselves by terror. Their oppression was endured for some time without resistance, until the attempted rape of Virginia by Appius Claudius, under the guise of a public judgment, and the blood of the virgin shed by her own father to save her honor, roused the public indigna-

tion to an outbreak, which overthrew the decemvirate, and caused its abolition.—The *decemviri litibus* (or more anciently *slitibus*) *judicandis* formed a judicial magistracy, which replaced the former authority of the pontifices in matters relating to persons and taxable property, and had the management of the *subhastationes;* under the emperors they were the presidents of the centumviral court.—The *decemviri sacris faciundis* (or more briefly *sacrorum*) formed a priestly college for the interpretation of the Sibylline books (established 368 B. C., instead of the ancient patrician *duumviri*); they were chosen for life, partly from the patrician, partly from the plebeian order, and had the management of the Apollinian and secular games. At a later period their number was increased, probably by Sylla, to 15.

DECHAMPS, Adolphe, a Belgian journalist and statesman, born at Melle, June 17, 1807. Early in life a disciple of Lamennais, he subsequently became an orthodox Roman Catholic. From 1843 to 1845 he was minister of public works, and from 1845 until Aug. 1847, when the triumph of the liberal party led to his secession, minister of foreign affairs. From 1837 to 1851 he conducted the Catholic *Revue de Bruxelles*, founded by himself and Dedecker. He is an able administrator and an influential parliamentary speaker.

DE CHARMS, Richard, an American clergyman and author, born in Philadelphia, Oct. 17, 1796. His ancestors on the male side were Huguenots, who took refuge in England upon the revocation of the edict of Nantes. In 1793 his father, a physician by profession, emigrated to America, and died of the yellow fever a few weeks before the birth of his son. The latter, when 14 years of age, supported his mother and himself by working in a printing office, until ill health compelled him to desist. Subsequently he found the means to enter Yale college, at which he was graduated in 1826, and at the suggestion of a female friend, to whom he was indebted for his education, commenced the study of theology in London, with a view of fitting himself for the ministry of the church of the New Jerusalem. During the 2 years he remained in England he supported himself by his labor as a journeyman printer. He has been settled at Cincinnati, Philadelphia, and Baltimore, and has published several collections of sermons and lectures on the fundamental doctrines of Swedenborg. To the periodical literature of his church he has also rendered valuable service in the establishment of the "New Jerusalem Magazine" in Boston, the first 3 numbers of which were printed by his own hands, and by editing the "Precursor" and "New Churchman." His chief work is the "New Churchman Extra" (1 vol. 8vo.), which is devoted to polemics and church history.

DECIDUOUS (Lat. *deciduus*, from *decido*, to fall), in botany, a term applied to such plants as drop their leaves at periodical seasons. In the temperate and northern latitudes this occurs for the most part on the approach of winter, or in early autumn. There are, however, marked exceptions; many kinds of oak retain their dry foliage until the next spring, in which case the leaves are called persistent.

DECIGRAMME. See Gramme.

DECIMAL, a calculation proceeding in a geometrical progression whose ratio is 10; that is, by tens, hundreds, &c., or by tenths, hundredths, and so on. Decimal arithmetic is the system in common use, in which the value of a figure increases tenfold with every remove to the left, and decreases a tenth by every remove to the right, the point between the units and tenths being designated by a period. Decimal division was doubtless suggested by the fingers of the hand, and therefore may be called natural; but other systems, as the binary and duodecimal, possess certain advantages over it. So long, however, as arithmetic uses a decimal ratio, it will be most convenient, for all purposes of calculation, to have money, weights, and measures divided decimally, as was done under the French republic.

DECIMATION, a Roman military punishment which was inflicted when the entire body of criminals was too large for condemnation. The names of the guilty were put into an urn or helmet, and as many having been drawn out as amounted to $\frac{1}{10}$ of the entire number, these were punished.—Blücher decimated a corps of Saxon mutineers just before the battle of Waterloo.

DECIUS, Caius Messius Quintus Trajanus, emperor of Rome from 249 to 251, born in Pannonia, was the successor of Philip. When the legions of Mœsia revolted against that emperor, Decius, who had spoken in the senate against submissive measures, was sent to bring them back to their allegiance. But the revolted army compelled him, under threats of death, to assume himself the purple, and to march at their head against Philip. While so doing he is said to have still secretly assured his former master of his fidelity, and promised submission as soon as he should reach Italy. Philip hastened to meet him in the field, but lost the battle of Verona and his life. The short reign of Decius is remarkable for a severe persecution of the Christians, an attempt to restore the ancient independent censorship, and with it the former virtuous manners and habits of the republic, and for the first invasion of the Goths from the neighborhood of the Black sea. To defend the northern provinces of the empire against this people, Decius hastened to the Danube, but fell with his son in battle.

DECIUS MUS, Publius, the name of 3 celebrated Roman plebeian consuls, father, son, and grandson. The first distinguished himself, in the year 343 B. C., in the war against the Samnites, and commanded, in 340, with his colleague Titus Manlius Torquatus, against the Latins, who at that time were trying to shake off the yoke of the Romans. Before a decisive battle, it is said, both consuls had a vision informing them that the infernal gods required one of the contending armies and the opposing commander to be

devoted to them. The consuls agreed between themselves that he whose wing should first waver should devote himself and his enemies to death. The wing of Decius gave way; he immediately caused the pontifex maximus to perform the consecrating rites, wrapped himself closely in his robe, spurred his horse into the thickest of the enemy, and perished. His legions, sure of success, rushed on anew and were victorious.—His son imitated this act of self-sacrifice in the battle of Sentinum (295), where he was opposed to the Gauls. Similar patriotism is attributed to the grandson in the war against Pyrrhus and the Tarentines, which, however, he survived.

DECIZE (anc. *Decetia*), a French town, arrondissement of Nevers, department of Nièvre, pop. 4,000, built on an island in the Loire, at the junction of the Aron with that river and at the head of the Nivernais canal, connected with one bank of the Loire by a suspension, and with the other by an immense stone bridge. On a rock which forms the highest point of the island stands an old castle formerly belonging to the dukes of Nevers, and used since 1849 as a hospital. In the same year a monument was dedicated here to Guy-Coquille, the famous jurist of the 16th century. The country around Decize contains some of the richest coal mines in France, and the town has large iron works and an extensive manufactory of bottles. The navigation through the canal of Decize, which is a branch of the lateral canal of the Loire, amounted in 1852 to 61,356 tons.

DECKER, or Dekker, Jeremias de, a Dutch poet, born at Dort about 1610, died in Amsterdam in Nov. 1666. His writings consist of a paraphrase of the Lamentations of Jeremiah, translations and imitations of classic poets, and a great number of epigrams. The most celebrated of his poems, the "Praise of Avarice" (*Lof der Geldzucht*), has earned for itself a place beside the *Moriæ Encomium* of Erasmus. A first edition of these appeared in Amsterdam in 1656, another edition with additions in 1702, and a complete collection of his poetry in 1726. Selections of his epigrams are contained in Geysbeck's *Epigrammatische Anthologie* (1821), and of his poetry in Siegenbeck's *Proeven van Nederduitsche Dichtkunde* (1823).

DECKER, Thomas, an English dramatic author, of the reign of James I., supposed to have died about 1638. He is now chiefly remembered by his quarrel with Ben Jonson, who, representing himself as Horace, satirized him as Crispinus in the "Poetaster," to which Decker replied by attacking Jonson in his "Satyromastix" under the name of "Young Horace." Decker wrote plays in conjunction with Massinger, Webster, and Ford, and was the sole author of several plays of considerable merit. Hazlitt remarks of one of them that it unites "the simplicity of prose with the graces of poetry." He wrote also many small works of a humorous cast, in the most important of which, "Gull's Hornbook" (London, 1609; a new edition by Dr. Nott, 4to., 1812), he ridicules the follies of London fashionable life.

DECLINATION of a heavenly body corresponds to latitude upon the earth; that is to say, it is the angle which a line drawn from the centre of the earth to the heavenly body makes with the plane of the equator. On June 20, the sun's declination is about 23° 28′ N.; Dec. 20, 23° 28′ S.; and March and Sept. 20, 0° 0′.

DECRESCENDO, in music, a direction to the performer to decrease the volume of sound from loud to soft. It is marked thus >:

DECRETALS, letters sent by the pope to bishops or churches for the regulation of ecclesiastical affairs. They form an important part of canon law, and enter largely into the collections of decrees bearing on that branch of legislation. The earliest known decretals are those of Pope Siricius, and the most ancient regular collection of them is found in the famous work of Dionysius Exiguus, who wrote in the 6th century. In a synod held at Rome in 494 decretals were pronounced of equal authority with the decrees of councils. (See Canon Law.)

DECURIONES, magistrates in the provincial *municipia* of the Roman state, corresponding to the senate at Rome. In the later times of the republic, the state was distinguished into two distinct parts, Italy and the provinces. Italy consisted, so to say, of a multitude of republics, whose citizens finally became members of the sovereign people, maintaining the internal administration of their own affairs. This municipal constitution was of great importance in the development of Italy. Originally the popular assemblies had the sovereign power in the municipia, and conferred the executive authority upon the decuriones. They consisted at first of 10 men, but in later times they frequently numbered more, and sometimes even amounted to 100. Each *curia decurionum* was presided over by 2 members who were called duumviri, and whose powers within their municipium resembled those of the Roman consuls during peace. Under the republic the whole administration of the internal affairs of their respective cities was in the hands of the decuriones, but after the establishment of the empire they exercised nearly all the circumscribed rights of the communities, though finally they were little more than receivers of taxes. The decuriones were created by election, and each decurio was required to be at least 25 years old, and to possess a certain annual income. Their election took place on the kalends of March.

DEDECKER, Pierre Jacques François, a Belgian statesman, born at Zele, in East Flanders, Jan. 25, 1812. In 1837 he established, in concert with Dechamps, the Catholic *Revue de Bruxelles*, which was continued until 1851. Since 1839 he has been a member of the chamber of representatives, in which he is one of the leaders of the Catholic party. With his friend Count Vilain he formed the ministry of March 30, 1855, in which he took for himself the department of the interior. When the

parliamentary debates on a new charity law called forth an uncommon political excitement, he tendered his resignation, with all his colleagues, Oct. 31, 1857. This step was severely censured by a large portion of his own party, but he was reëlected to the new chamber. He has written numerous works, among which are *Religion et amour* (1835 *et seq.*); *Du pétitionnement en faveur de la langue Flamande* (1840); *De l'influence du clergé en Belgique* (1843); and *De l'influence du libre arbitre de l'homme sur les faits sociaux* (1848).

DEDHAM, a township and the capital of Norfolk co., Mass., on Charles river, 10 m. S. W. from Boston; pop. in 1855, 5,633. It is connected with Boston by a branch of the Boston and Providence railroad, and is a favorite residence for persons doing business in that city. The court house is a handsome granite building, having a Doric portico on each front. The gaol is of hewn stone and well arranged. A canal 3 m. long, excavated in 1639 from Charles to Neponset river, gives a good supply of water power, which is used chiefly for cotton and woollen mills. Of the former there are 2, with a capital of $68,000, and of the latter there is 1, with a capital of $200,000. There are 2 furnaces, 1 machine shop, 1 soap and candle factory, 1 sugar refinery, 1 card factory, 2 tanneries, gas works, 1 bank, a savings bank, 1 newspaper office, a high school, 9 grammar schools, a library organized in 1855, 2 fire insurance companies, and 10 churches, viz.: 1 Episcopal, 2 Congregational, 2 Unitarian, 2 Baptist, 1 Methodist, 1 Universalist, and 1 Catholic.

DEE, the name of several rivers. I. A river of N. Wales, rising among the mountains of Merionethshire, in a small lake called Bala or Llyn Tegid, flowing N. E. through the vale of Llangollen, and forming part of the boundary between Cheshire and Denbighshire. At Aldford it enters Cheshire, and passes on to Chester, which it nearly encompasses, and where it has a width of 300 feet. Thence it is conveyed in an artificial channel along the marshes, a distance of 9 m., and finally empties into the Irish sea, through an estuary 14 m. long and from 2 to 6 m. broad. Its length, exclusive of the estuary, is about 80 m. It is much obstructed by sand banks at its mouth, and is not naturally navigable, but has been improved to admit of the passage of small vessels to a point 2 or 3 m. above Chester. Near Trevor it is spanned by an aqueduct 1,007 feet long, 120 feet above the water, and supported by 18 stone piers, which carries the Ellesmere canal across the vale of Llangollen; and at a short distance from this structure is another of still greater size and beauty, on which the Shrewsbury and Chester railway crosses the Dee at a height of 150 feet above its surface. This viaduct has 19 arches of 90 feet span, is 1,530 feet long, and is built almost wholly of stone. II. A river of Aberdeenshire, Scotland, rising in the Cairngorm mountains, flowing E. about 96 m., and entering the North sea at Aberdeen. It has valuable salmon fisheries, which have lately yielded $40,000 a year. III. A river of Kirkcudbrightshire, Scotland, with valuable salmon fisheries. It enters Solway frith after a course of about 50 m. IV. A river of Ireland, counties of Meath and Louth, 21 m. long, flowing into Dundalk bay. V. A branch of the river Derwent, in Van Diemen's Land, co. of Cumberland.

DEE, JOHN, an English mathematician and astrologer, born in London, July 13, 1527, died at Mortlake in 1607 or 1608. He was educated at Cambridge university, and attained much proficiency in the science of the time. After a short tour in Holland he was elected fellow of Trinity college, and in 1548 took his degree of master of arts. Incurring the suspicion of being a conjurer, he repaired to the continent, resided 2 years at the university of Louvain, and visited France, spending some time at the college of Rheims, where he gave several lectures on mathematical theorems, which he however elaborated into metaphysical and astrological dogmas which were received with great applause. On his return to England in 1551 Dee's learning recommended him to the patronage of Edward VI., who conferred on him a pension of 100 crowns, which he afterward relinquished for the rectory of Upton on Severn. Shortly after the accession of Mary he was accused of practising against the queen's life by enchantment, and he was subjected to a protracted trial and long imprisonment, but released in 1555. On Elizabeth's accession he was introduced to the queen, and requested to name a propitious day for the coronation. He again returned to the continent for some time, where he was supposed to have acted as a secret agent of the English government, and visited the court of Maximilian, to whom he presented and dedicated one of his works. When in 1571 he fell dangerously ill abroad, the queen sent 2 of her own physicians to his relief. After his return he settled at Mortlake, Surrey, where he was engaged for some years in his favorite pursuits and studies, and calculated horoscopes and nativities for private patrons. In 1576 the people in the neighborhood attacked his house from prejudice against his occult science, and he barely escaped with life, his furniture and apparatus being all destroyed. He was sent abroad again in 1578, ostensibly on a mission to consult with German physicians touching Elizabeth's health, but probably for some secret political object. On his return he began that career on which his celebrity principally rests. In 1581 he made the acquaintance of one Edward Kelly, an apothecary of depraved character, who had had his ears cropped for forgery, but of considerable talent. This man pretended to be as sincere a devotee to magic as was Dee himself; and with his assistance spirits were raised and information obtained by use of a crystal, or magic mirror, in which, after invocation, responses were granted to their inquiries. In 1583 they made the acquaintance of Albert Laski, a Polish nobleman, an inquirer into kindred subjects, and at his request they

accompanied him abroad. They exhibited before the emperor at Prague, and resided there for a time, asserting that they had the art of transmuting metals, which enabled them to live in considerable splendor. At Prague Dee and Kelly separated. The former returned to England, and was appointed (Dec. 8, 1594) chancellor of St. Paul's cathedral, and in the following year warden of Manchester college, which he left in 1602 or 1604 to return to his old residence near London. A catalogue of his printed and published writings is contained in his "Compendious Rehearsal of his Life and Studies," prepared in 1592, on the appointment of a commission by Elizabeth to inquire into his circumstances. His diary was printed in 1842 by the Camden society, together with the catalogue of his library of MSS., which he had made himself before the pillage of his house by the mob, and which contains the titles of several mediæval works, not now known to be in existence. Dr. Dee's "Relation of what passed for many years between him and some Spirits," edited by Casaubon, appeared in London in 1659. One of his magic mirrors is in the British museum.

DEED (Lat. *factum*, Nor. Fr. *fait*), a term originally employed to express an act for the disposition of lands, which at an early period was by the actual or symbolical delivery of possession in the presence of witnesses; but when a writing was substituted in place of this formality, the same name continued to be applied. A deed is now understood to be an instrument in writing and under seal whereby real estate or some interest therein is transferred. In English conveyancing it is designated as an indenture where there are several parties, counterparts being made on parchment, the edges of which are cut like the teeth of a saw to correspond each with the other. A deed poll (polled or shaved even) is one purporting to be executed by a single party. The term indenture is used in this country simply as expressing that there are several parties; and though in form the deed usually purports to be executed by all the parties named, yet in fact the ordinary deed of lands is executed by the grantor only. The deed which is chiefly used in the United States is what in the English law is called a conveyance by bargain and sale (see that article). In some of the states, however, no particular form is required if the intention be clearly expressed; as in Massachusetts by a provincial act, in New York by the Revised Statutes of 1830 (1 R. S. 738), and in several other states by a similar provision. Even in those states where no statute regulation has been adopted, a simple form has generally come into use, having very little analogy to the English bargain and sale, except that the technical words "bargain and sell" are retained. By the New York statute the word "grant" is substituted in place of all the phraseology used in the different forms of English conveyances. By a singular confusion of the original intent of the phrases peculiar to each conveyance, before the enacting of that statute the whole were combined together in a deed drawn with much professional care, as enfeoff or grant, give, bargain and sell, demise, release, confirm, &c.; in which we have the operative words of a feoffment, donation or gift in tail, the conveyance by bargain and sale under the statute of uses, and the conveyance by lease and release; and this undiscriminating use of terms is still kept up to some extent for the satisfaction of those who attach importance to old forms of expression. A consideration is said to be essential to the validity of a deed, but this is to be understood with reference to other persons than the parties to the deed. A gift or voluntary conveyance is effectual except as it may affect creditors or subsequent purchasers. Under the statutes in England and this country against fraudulent conveyances, a deed wholly without consideration would be held void as against the creditors of the grantor or subsequent purchaser without notice. In England it is held to be void even if the purchase was made with knowledge of the prior voluntary deed; but a different rule prevails here. A consideration may be either good or valuable, the former being founded upon natural affection between near relations, and it is presumable that it may extend to those who hold such relationship by adoption; the latter (*i. e.* valuable) is what has a pecuniary value, as money or its equivalent. It is not altogether settled how far a consideration of natural affection will sustain a deed against creditors; it probably would be held sufficient if there was no other circumstance from which it could be inferred that the intent was to remove the property out of the reach of creditors. Insolvency at the time of executing the deed would be such a circumstance; yet if not known to the grantor at the time, it would give rise to a serious question. The Revised Statutes of New York declare that the want of a valuable consideration shall not alone be sufficient to avoid a deed as fraudulent (2 R. S. 137). In common law conveyances it was not necessary that the consideration should be expressed, nor was it necessary to prove one, the conveyance itself being an act of such formality that the law raised the presumption of a consideration; but in deeds which were introduced under the doctrine of uses held in courts of equity, it was essential that a consideration should be shown, which might be either by being expressed in the deed, and then, under the general rule applicable to sealed instruments, it could not be controverted by parties or their privies; or it might be proved whenever the deed was brought in question. It was necessary, however, that the deed should purport to be for a pecuniary consideration, as this was essential in order to raise a use, but the sum need not be mentioned; and whatever might be the sum expressed or proved, it was sufficient to give effect to the deed. Hence arose the common form of expressing a consideration of $1; and this again gave rise to an anomaly in respect to sealed instruments, viz.: that the actual amount of the consideration, and whether paid or not, might

be inquired into, when essential for other purposes than the mere validity of the deed, notwithstanding a sum had been named or the receipt acknowledged. It has indeed been held that in order to prove any other than a pecuniary consideration it is necessary that there should be some expression in the deed to warrant it, as "for divers other considerations." These rules, which had respect to deeds of bargain and sale, will generally apply to the simpler forms which have been substituted. A deed was at common law the most artificial of all forms of contract. Certain operative words belonged to each of the different conveyances, and no others could be used with the same legal effect, as enfeoff or give (*feoffavi* or *dedi*), in the conveyance of the fee; give or grant (*dedi or concessi*), in the conveyance of incorporeal hereditaments; demise, grant, and to farm let, in a lease; and so of others. A second peculiarity was that certain obligations resulted from the use of these terms without being otherwise expressed, which were called covenants in law. Thus to the words "enfeoff or give" was annexed a warranty by which the grantor vouched for the title, and upon failure thereof was bound to render lands of equal value; but this being by statute limited to the grantor, an express clause of warranty was introduced into the deed in order to bind his heirs. This gave rise to what Chief Justice Coke declared to be "one of the most curious and cunning learnings of the law." The heir was bound upon the presumption of law that he had received from his ancestor an equivalent; and though he was not compelled upon failure of title to render an equivalent to the grantee unless he had himself received other lands by descent from the warranting ancestor, yet he was barred from making a claim to the lands warranted if he might have derived title from him who made the warranty. The same rule was unjustly extended to a case where the title to the warranted lands could not by possibility have come from the warrantor; as when the husband, having an estate for life as tenant by the curtesy in lands belonging to the wife, conveyed with warranty, the son who would have taken as heir of the mother was barred from claiming the estate. This is the doctrine of lineal and collateral warranties, to understand which fully it is necessary to bear in mind that it was first introduced for the purpose of avoiding the old feudal rule of non-alienation of lands without consent of the heir. By various statutes in England, collateral warranties are now abrogated, except when assets have descended from the ancestor who warranted. Both lineal and collateral warranties have been abolished in the state of New York, and it is further declared that no covenant shall be implied in any conveyance of real estate, and heirs and devisees are liable upon the express covenant of the ancestor or testator only to the extent of lands which descend or are devised to them. (1 Rev. Stat. 739, § 140, 141.) In those states where similar statutes have not been enacted, it is held that the word "give" implies a warranty during the life of the grantor; that the words "grant, bargain, and sell" do not imply a covenant of title in a conveyance in fee, but that "grant or demise" does imply such a covenant in a lease for years. Express covenants have both in England and this country taken the place of the ancient warranty. The covenants usually inserted are these: 1, that the grantor is lawfully seized; 2, that he has good right to convey; 3, that the land is free from encumbrances; 4, that the grantee shall quietly enjoy; 5, that the grantor will warrant and defend. These are personal covenants, and the remedy for a breach is only against the covenanter or against his heirs or assigns to the extent of lands descended or devised. The covenants of warranty and for quiet enjoyment are broken only by actual eviction; hence they are said to run with the lands, and may be taken advantage of by the heirs or assignees of the grantee. But the other covenants not being prospective, but being broken if at all at the time of the execution of the deed, become what are called *choses in action*, and are not assignable. The measure of damages for a breach of these covenants is the price paid for the lands with interest, the rule being founded upon the supposed value of the lands at the time of the execution of the deed; and the rule is the same although the land has since risen in value, or the grantee has himself made improvements. The covenant against encumbrances may be an exception, as the damages recoverable is the sum paid to discharge the encumbrance, and this may in some cases exceed the consideration or price of the lands. As to the parties to a deed, the general rules have been stated in the article Contract. An important innovation has, however, been recently made in many of the states in respect to the capacity of a married woman to convey, which will be more properly considered under the title Husband and Wife.—The recording of deeds is universal in this country; and although the suggestion was derived from a local practice in some parts of England, yet it is still very limited in that kingdom, being probably uncongenial to the large landed proprietors, who usually have private family arrangements which they would be unwilling to make subject to public inspection. For the purpose of recording, it is a requisite in all the states of the United States, that the deed should be acknowledged or proved before some officer authorized to take such acknowledgment or proof, whose certificate is to be affixed to the deed; and in several of the states 2 subscribing witnesses are required. In the state of New York a subscribing witness is not required when the deed is acknowledged, but is of course necessary when it is proved. The general provision is, that an unrecorded deed is inoperative against a subsequent purchaser in good faith and for a valuable consideration, whose deed shall be first recorded. It is, however, understood that actual knowledge of a previous deed by the subsequent purchaser would be equivalent to a registry,

which is but constructive notice; or in other words, he would not be held to be a *bona fide* purchaser within the meaning of the statute.

DEEG, a town of Hindostan, in the native state of Bhurtpoor, 24 m. W. from Muttra, lat. 27° 29′ N., long. 77° 23′ E., formerly celebrated as a strong fortress. The natives supposed it impregnable, but it was taken by storm, Dec. 23, 1804, by the English, and was dismantled in 1826 after the capture of Bhurtpoor.

DEEMSTERS, or Demsters (Saxon *dema*, a judge, or umpire), the name given to certain judges in the isle of Man, chosen annually from among the people. There are 2 for each division of the island, and they have authority in all civil and criminal cases. In deciding the law in cases of emergency, they have the assistance of the house of keys.

DEEP RIVER, one of the head streams of Cape Fear river. It rises in Guilford co., N. C., flows S.E. through Randolph co., then nearly due E. into Chatham co., where it unites with Haw river to form the Cape Fear. It is about 100 m. long, and furnishes good water power. It has recently been rendered navigable from its mouth to the mines of anthracite and bituminous coal which are worked near its banks in Chatham co. It was called by the Indians Sapponah.

DEER, the common name applied to an extensive group of ruminating animals, embraced in the family *cervidæ* of authors. This group, which includes animals varying in size from the small muntjac to the gigantic moose, is characterized in most genera by the presence in the males of solid horns arising from the frontal bone, falling off annually in the large species, and covered when first developed by a hairy skin. They are remarkable generally for the lightness and elegance of their forms, the velocity of their movements, and the timidity of their disposition; they are found in all parts of the world, and are valuable as furnishing food, clothing, and beasts of draft for many northern nations. The forms of the horns or antlers are very various, being sometimes flat and palmated as in the moose, or nearly round and branching as in the stag; their substance is very different from horn, being compact and solid, without any central core like that of the antelope and ox family; their production is intimately connected with the generative function. In the young animal a kind of exostosis, or bony growth of great hardness, is perceptible on each side of the frontal bone; this increases rapidly, pushing the skin before it; the enlarged vessels are compressed and obliterated by the growing horn, the cutaneous envelope dies, and the exposed horn in time is cast off; under the wound, which rapidly cicatrizes, a new horn soon rises with a burr around it; during the rutting season the reproduction of the horn is most active, with considerable heat and irritation; when it is fully developed the skin falls as before, leaving the hard and bare horn, which falls and is reproduced; at each successive growth the horn increases in size and complexity, but its duration is the same. When the horns fall, the animal retires into the thick forests, not appearing among the herd of females until these organs reappear; when the horns are covered, they are said to be "in the velvet." The broad form of the horns, as in the reindeer, is a provision of nature to enable them to clear away the snow in search of food. The origin of the horns is called the burr, the main shaft the beam, and the branches the antlers; the latter may be near the head, when they are termed brow antlers, or in the middle of the beam (median or bezantlers); the termination of the beam is sometimes styled a perch, and the small processes snags and prickets. The teeth of the deer are 8 incisors in the lower jaw, and none in the upper, in their place being a callous pad; generally there are no canines, but these exist in the upper jaw alone in a few species; there is an empty space between the incisors and the grinders, the latter being 6 on each side in each jaw, with the crown marked by the disposition of the enamel in 2 double crosses, whose convexity is turned inward in the upper teeth, and outward in the lower. The feet end in 2 toes, each with its sharp hoof, resembling a single hoof which has been cleft; behind and above these are 2 small rudimentary toes or hoofs. The 2 metacarpal and metatarsal bones are united into a single cannon-bone. The head is long, and terminated in most by a muzzle; the ears are large, the pupils elongated, and the tongue soft; there are 4 inguinal teats. The skeleton is constructed for lightness and rapid springing motions; the neck is long to permit grazing, and the spines of the dorsal vertebræ are long and strong for the origin of the thick ligamentum nuchæ to support the ponderous head; the cavity of the skull is small, in conformity with the limited intelligence of the group. The internal structure is that of other ruminants feeding only on vegetable substances; they have no gall bladder. The external covering consists of close and thick crisp hair, with a kind of wool next the skin in the species of cold regions; the general color is a variety of shades of brown, with rufous tints and white spots. The senses of smell, hearing, and sight are very acute, enabling them to detect their enemies at a distance, and escape by flight; under the eye in most is a sinus, which has been supposed by some to communicate with the nose; it secretes largely a viscid fluid like tears, whence the French call these gland-containing sacs *larmiers;* they communicate with the nose by the lachrymal ducts; the secretion is the most profuse during the rutting season. Deer are capable of a certain degree of domestication, and the reindeer may be completely subjected to man; some species reside in thick forests, others in open plains, and others in swampy districts.—All the arrangements of this group are more or less artificial and unnatural; but there are several subdivisions generally admitted, founded on similarity of structure and on geographical limitation, which are

of advantage in classification. Cuvier, De Blainville, and more especially Col. Hamilton Smith, made the horns the basis of division into subgenera; Mr. J. E. Gray and Dr. Sundevall have pointed out some other external distinctions which they believe more characteristic of genera and species than modifications in the form of the skull, teeth, and horns, as they are not changed by age, and are evident in both sexes. These are the form and extent of the muffle, and the metatarsal hair-covered glands on the hind legs. In the "Annals and Magazine of Natural History" (London, vol. ix. 1852, p. 413) is a paper by Mr. Gray, which presents a good synopsis of the varieties of deer. He divides them as follows: I. Those of snowy regions, with broad muzzle entirely covered with hair, expanded and palmated horns, short tail, and their fawns not spotted; containing (*a*) the alcine deer, with no basal anterior snag to the horns, and a small bald muffle between the nostrils, as in the genus *alce*, the elk or moose; (*b*) the rangerine deer, with a large basal anterior snag, close to the crown or burr, and no muffle, as in *tarandus*, the reindeer. II. Those of temperate and warm regions, with a tapering muzzle ending in a bald muffle; the fawns, and sometimes the adults, spotted; containing (*c*) the elaphine deer, with an anterior basal snag, the muffle broad and separated from the lip by a hairy band, and the tuft of hair on the outside of the hind leg above the middle of the metatarsus, as in *cervus*, the stag, and *dama*, the fallow deer; (*d*) the rusine deer, with an anterior basal snag, the muffle very high and not separated from the edge of the lip, and the metatarsal tuft as in the last division, as in the genera *panolia*, *rucervus*, *rusa*, *axis*, *hyelaphus*, and *cervulus*; (*e*) the capreoline deer, with no basal anterior snag, the first branch being at some distance above the burr, the suborbital fossa generally small, as in the genera *capreolus* (roebuck), *furcifer*, *blastocerus*, *cariacus* (American deer), and *coassus* (the brocket). The 1st and 2d of these divisions are confined to the northern parts of both continents; the 3d to Europe and Asia, with the exception of the wapiti of North America; the 4th to the warm regions of Asia; the 5th to America, except the roebuck of Europe, and the ahu of central Asia. The alcine deer will be described in the article Elk, and the elaphine under Stag; the rangerine have been described under Caribou.—Of the rusine group, or samboos, confined to south-eastern Asia and its islands, the 1st genus in order is *panolia* (Gray), and the species sungnai deer (*P. Eldii*, Gray); in this genus the round horns curve backward and outward, with the upper part bent in and forked, rather expanded on the inner edge; the yellowish brown fur rigid and flattened; a large, oblong, and deep suborbital pit, with the nasal bones short, broad, and dilated behind; the frontal snag sometimes has a tubercle or branch at the base. In the genus *rucervus* (Hodgson), the horns are cylindrical, repeatedly forked at the tip; the tail short and thick, a well developed tear-bag, broad rounded ears, covered with hair, and narrow compressed hoofs; the fur is soft, with indistinct spots, and without pale tint on the rump; the face is long and narrow, the opening of the nose large, and the suborbital pit shallow. The species is the bahraiya deer (*R. Duvaucellii*, Cuv.), of a yellowish brown color on the tips of the black hairs; an indistinct dark streak on the back, with a row of white spots on each side; hair of neck, throat, chest, and belly longer, with scattered grayish hairs; muzzle and front of leg dark; chin white; fur in winter dark brown. In the genus *rusa* (H. Smith), the horns are on a moderately long peduncle, and simply forked at the tip, with an anterior frontal snag close to the crown; the hair is hard, rigid, and thick, elongated in the males of the larger species into a kind of mane on the neck; they have canine teeth. The black samboo deer (*R. Aristotelis*, Cuv.) is of a blackish brown color, with the feet, vent, and spot over the eye fulvous; tail brown, with dark tip; the skull is about 17 inches long, with a very deep triangular suborbital pit: a large and beautiful animal, inhabiting India and Ceylon. The spotted rusa (*R. dimorphe*, Hodgs.) is of a red-brown color, with white spots on the back and sides, neck and belly blackish, chin white. The Malayan samboo (*R. equinus*, Cuv.) is plain brown, with a rounded, floccose, black-tipped tail; this inhabits Sumatra and Borneo, and is the eland or elk of the Dutch sportsmen. The Javan rusa (*R. hippelaphus*, Cuv.) is remarkable for its ample mane, giving it a resemblance to a horse, whence its specific name; its color is dull brown, and the hair thick, dry, and frizzled; it stands more than 3 feet high at the shoulders; it inhabits Java. The smaller rusas have no manes, and the elongated peduncles of the horns are covered with hair. Among these are the smaller rusa (*R. Peronii*, Cuv.), brown, paler beneath, with the anal disk white, hind part of feet hairy, and horns thick and heavy, inhabiting Timor and the neighboring islands; the Philippine rusa (*R. Philippinus*, Desm.), with brown forehead, end of nose brownish, feet naked behind, hair rigid and not waved, resembling the muntjac in its horns, but without the ridge and the facial grooves of the latter; and the little rusa (*R. lepidus*, Sundev.) of Java, of a reddish brown color, back and sides varied with pale, vent disk white with black edge above, not so large as the roebuck. The genus *axis* (H. Smith) is characterized by horns similar to those of *rusa*, but more slender, by the absence of canines and mane, by an elongaged tail, and by the smaller size; the hair is thick, polished, fulvous, with beautiful white spots at all seasons; the face is long and narrow, the ears large and acute, the legs long and slender; the suborbital pit is small but deep. The spotted axis (*A. maculata*, Gray) has a black streak on the back edged with a series of white spots; on the sides is an oblique curved line of similar spots, and a short oblique white streak across

the haunches; in size and markings it resembles the fallow deer, but its horns are quite different, being destitute of palmations. This species is abundant in Bengal, and is frequently hunted; it frequents thick jungles near water, feeds during the night, and is very timorous except in the breeding season; it is easily tamed, and in captivity is very nice in tasting its food; the height is about 2½ feet at the shoulders. The genus *hyelaphus* (Sundev.), which includes the hog deer, resembles *axis*, but is lower on the legs, and has no black dorsal streak, nor white streak on the haunches; the ears are short and round. The porcine deer (*H. porcinus*, Zimmerm.) is of a yellowish brown color, with obscure whitish spots, the front of face and legs darker, and white on the inside of the thighs; it inhabits the jungles of India, and, notwithstanding its thick and clumsy appearance, is a very active animal; the tail is bushy, and often carried erect. The genus *cervulus* (Blainv.), the last of the rusine division, inhabiting eastern Asia, will be described in the article Muntjac.—Of the capreoline deer, the genus *capreolus* (H. Smith), containing the European roebuck and the Siberian ahu, will be described in the article Roebuck. The genus *furcifer* (Wagner and Sundev.) has the horns erect, forked, without any basal snag, acute narrow ears, and a short tail; the hair is thick, brittle, and waved; there is a distinct pencil of hairs on the inside of the hock, but none on the outer side of the metatarsus (in which it differs from *capreolus*). The taruga (*F. Antisiensis*, D'Orbigny) is of a yellowish gray color, with the edge of the muffle and throat white; face with a brown streak, and a band between the eyes; hoofs broad; it inhabits the mountains of Bolivia, and the east coast of South America. The gemul (*F. huamel*, H. Smith) is darker colored, with the inside of the ears white; this species, considerably larger than the roebuck, inhabits the mountains of eastern South America and Patagonia. The genus *blastocerus* (Wagn. and Sundev.) has horns straight, erect, 3-branched, without basal snag; a very short tail and large ears; hair very thin and soft, the tuft on legs as in *furcifer*. The guazupuco deer (*B. paludosus*, Desm.) is nearly as large as the stag; the general color is fulvous, but the inside of the ears and limbs and the lower parts of the breast are white; the face marks and feet are blackish, and the under surface of the tail white; it inhabits Brazil and Paraguay. The guazuti deer (*B. campestris*, Licht.) is much smaller than the last, standing about 2½ feet high at the shoulders; the horns are more slender, and about a foot long, generally with 2 snags; the color is fulvous brown; the hairs of the nape and back reversed; the hoofs are narrow. This beautiful animal inhabits the open plains of Patagonia, and is so swift of foot that, according to Azara, a horse cannot overtake it; the flesh of the young is delicate, but that of the adult strongly flavored.—The genus *cariacus* (Gray), which contains our common deer, has the horns cylindrical, tending to flatten, strongly bent back and then forward, with a central internal snag, the tip bent forward, and several lower branches on the hinder edge; the hair is soft and thin, and the moderately long tail has long hair on the under side; the ears are large and rounded; there is generally a tuft of white hair on the hind leg, rather below the middle of the metatarsus; the suborbital pit in the skull is shallow, and the nasal bones broad and subtriangular behind; the hoofs are generally narrow and elongated. The common American deer (*C. Virginianus*, Penn.) has rather a long head and sharp muzzle, large and lustrous eyes, and the lachrymal bags covered by a fold of the skin; the legs are long and slender. The color in summer is bright fulvous, in autumn of a leaden hue, and in winter dark brown, when it is longer haired above; the lower parts from chin to end of tail are white; the sexes are very much alike. The young, till about the age of 4 months, are bright reddish brown, with irregular longitudinal white spots; after this age they resemble the old ones. The length of this species from nose to root of tail is about 5 feet 4 inches, and the length of tail, including the hair, 13 inches, the bones being only 6 inches; the ear is 5½ inches high. From the observations of Dr. Bachman, as given in the "Quadrupeds of North America" (vol. iii. p. 168), it appears that in the one-year-old male the horns had each a rudimentary prong about ⅝ of an inch long, and another scarcely visible; when 2 years old, 2 prongs, from 4 to 6 inches long; when 3 years old, 3 prongs, the longest 8 inches, with brow antlers; when 4 years old, the brow antlers longer and curved, and larger in diameter; during the next 2 years, the animal seemed to lose its vigor, and the horns diminished in size; perhaps in the wild state the horns would have been somewhat larger. As a general rule, the horns become annually longer and more branched, until the animal arrives at maturity, when they begin to decline; when the operation of castration is performed while the horns are fully grown, they are said to continue for years, and after they have dropped there is no subsequent growth. This graceful animal is the most useful of the wild game of North America; its flesh forms a palatable and easily digestible article of food; its skin is made into various articles of clothing both for civilized man and the savage; its horns are useful for handles of different kinds of cutlery; its very sinews form the bow-strings and snow-shoe netting of the North American Indian. Though very timid, it lingers around its old haunts when invaded by man and persecuted by the hunter; during the day, it retires to thickets and swamps, coming out to feed and drink by night; in hot weather, it is fond of immersing itself deeply in ponds and streams. The food of the deer in winter consists of buds of the wild rose, hawthorn, brambles, and various berries and leaves, and in spring and summer of the tenderest grasses; it not unfrequently visits the fields

of wheat, oats, maize, and cow peas; berries, nuts, acorns, and persimmons are also favorite articles of food. They are in fine order from August to November, when in the southern states the rutting season begins; during this period, which lasts about 2 months, the neck of the male increases in size; the males meeting, tremendous battles ensue, resulting often in the death of one or both of the combatants; about January the horns are dropped, and they associate peaceably together, as if conscious of their weak and defenceless condition; in about 3 weeks after the shedding of the horns, the swellings of the new ones begin to appear, soft, tender, vascular, rapidly growing, accompanied by considerable heat, and covered by a soft downy skin called the velvet; when these are fully grown, in July or August, this dry covering is rubbed off against the trees, and the horns become solid and smooth. The females are fattest from November to January, gradually getting thinner toward the end of gestation, and growing quite lean while suckling the young. The young are born in April, May, or June, according to latitude; Audubon says that in Florida and Alabama most of the fawns are brought forth in November. The young are carefully concealed, and are visited by day only occasionally, as at morning, noon, and night; they are easily domesticated, but are troublesome pets. The hind does not produce young until she is 2 years old, and the number of fawns varies from 1 to 3 at a birth; she is much attached to her young, and the imitation of their cry is often practised by the Indians to bring the mother within reach of their weapons. Deer are gregarious, being found in herds of several hundreds, the sexes separate except during the rutting season; their sense of smell and hearing are very acute, as every hunter knows; the sense of sight is not so acute, and the voice is quite imperfect. Preferring to roam at night in search of food, it frequents the banks of water courses and the salt licks, where great numbers are destroyed. In walking, the deer carries the head low, the largest animal usually leading the herd, which advances in single file; when alarmed, it gives 2′ or 3 high and exceedingly graceful springs, and, if it sees any danger, rushes off with the speed of a race horse, running low, with the head in a line with the body. Deer take to water readily, and swim with their bodies deeply submerged, and so rapidly that nothing but an Indian canoe can easily overtake them. The deer has been hunted by the Indians for ages with the bow and arrow; the white man hunts it with the rifle in the rocky districts, chases it with hounds in the open country of the South, or kills it when dazzled by a bright light in the woods. The deer are growing scarce in all but the unsettled parts and inaccessible swamps and thickets of the United States, and will soon become extinct unless stringent laws are made and enforced against killing them out of season; they are found, however, in every state of the union, in Canada and the British provinces, in Texas and in Mexico; in California this is replaced by the black-tailed species. Those found in the mountains are larger and shorter legged than those of the swamps of Carolina and the Atlantic seaboard. It is generally believed that the *C. Mexicanus* (Licht.), *C. nemoralis* (H. Smith), and *C. gymnotis* (Wiegm.), all from Mexico, are only varieties of the common Virginian deer. A different species, however, is the black-tailed or Californian deer (*C. Richardsonii*, Aud. and Bach.; *C. Columbianus*, Rich.). The male is a little larger than the common deer, but shorter and stouter in form; the horns are twice forked, the first fork being 10 inches from the base, the antlers somewhat like those of the European stag; the ears are of moderate size, the head shorter and the nose broader than in the first species; the hoofs are narrow and pointed; the lachrymal openings large, and close under the eye; the tail short and bushy. The general color is reddish brown above and white beneath, with no light patch on the buttocks; the chest blackish brown, which encircles the shoulder like a collar; a dark line from under chest to middle of belly; the tail dark brown, becoming black at the top, and white below. The length to root of tail is 5½ feet, tail 9 inches; height at shoulders 2½ feet; width of horns between superior prongs 1⅝ feet. First noticed by Lewis and Clark near the Columbia river, it has become recently well known to the Californian miners; it seems to replace the common deer to the west of the Rocky mountains. The flesh is tender and of good flavor. Less graceful than the common deer, and more bounding in its movements, it is said to be very swift; it also breeds earlier in the season. It is found from California to the Russian possessions. The Columbian black-tailed deer (*C. Lewisii*, Peale) may be merely a variety, according to season or locality, of the last named; but Audubon and Bachman think it will prove different. The long-tailed deer (*C. leucurus*, Douglass) is smaller than the Virginian, with the head and back fawn-colored, mixed with black; sides and cheeks paler; white beneath; tail brownish yellow above, reddish near tip, and cream-white below. The form is elegant, lachrymal opening small, limbs slender, hoofs sharp-pointed, and tail long; the fur dense, coarse, and long, with a tuft on the belly between the thighs. The length is only 4 to 5 feet to root of tail; tail 13 inches. In appearance and manner of jumping it resembles the roebuck; the flesh is excellent. According to Richardson, this species is not found on the east side of the Rocky mountains beyond lat. 54°, nor to the eastward of long. 105°; Douglass says that it is the most common deer in the districts adjoining the Columbia river; it is also met with on the upper Missouri and Platte rivers, and in Washington territory. The mule deer (*C. macrotis*, Say.) is intermediate in size between the wapiti and the common deer, and is a noble-looking animal, the only drawback being its long ears; the

horns are twice forked; the lachrymal aperture is long, the hair coarse and crimped, the hoofs short and wide, and the tail almost without hair beneath. The general color of the hair above is brownish gray, shading into fulvous, the chin without any dark markings; the forehead dark brown, and the dorsal line nearly black; below grayish white; a yellowish white spot on the buttocks; tail pale ferruginous, with a black tuft at the end; the glandular openings on the sides of the hind legs are very long. In the female, the form and length of the ears resemble so much those of the mule that the origin and appropriateness of the common name are very evident. The length of a female measured by Audubon and Bachman was $4\frac{5}{6}$ feet to the root of the tail, and the tail to end of hair 10 inches; the height at the shoulders $3\frac{1}{4}$ feet, at rump $3\frac{1}{2}$ feet; length of ears 7 inches; the weight 132 lbs. The male would be considerably larger than this. Their habits are more like those of the stag than of the common deer; they fly far from the settlements, and when started, run a mile or two before stopping. The female brings forth one or two young in the month of June. This species ranges along the eastern sides of the Rocky mountains, from 54° N. to north-western Texas; it is found on the upper Missouri and Platte rivers and in Oregon, not extending to the Pacific. It is very likely that other species of this genus will be found in Central America by the various exploring and hunting expeditions constantly fitted out by individuals and the government.—In the genus *coassus* (Gray; *subulo*, H. Smith), the horns are simple, straight, and round, like those of a deer of the first year, and inclining backward; the ears are short, broad, and almost naked; tail short; face rather convex; the fur short, elongated into a tuft on the forehead; legs without any external metatarsal tuft, but with a pencil of hairs on the inside of the hocks; the suborbital pit is small and shallow. This genus, which includes the brockets, is confined to tropical South America; they are of small size, living in woods and jungles. The pita brocket (*C. rufus*, F. Cuv.) is of a shining red color, with the crown and neck gray; the young are spotted with white, and the females are of a lighter red, with more gray. They inhabit the low, moist woods, and are polygamous, there being about 10 females in company with one male; they are very fleet for a short distance, but are soon tired out. The height at the shoulders is about 2 feet. The apara brocket (*C. nemorivagus*, F. Cuv.) is about 26 inches long, and resembles a sheep more than a deer. The lower parts of the head and lips are whitish; the inside of the fore legs, and from the lower breast to the buttocks, pale cinnamon-colored; the neck and rest of the body grayish brown. The eyebrowed brocket (*C. superciliaris*, Gray) differs from the pita in the deeply arched muffle and the white stripe over the eyes. The large-eared brocket (*C. auritus*, Gray) resembles the Asiatic muntjac in color, and the ears are large, broad, more than half the length of the head, with 2 lines of hairs. All these species inhabit Brazil and the eastern coast. On the western coast is another species, the venada deer (*C. pudu*, Mol.), with ears thickly covered with hair, a deep suborbital pit, and large molars; the fur is rufous, blackish in front and behind; the ears and tail are very short. It inhabits Chili.

DEER GRASS (*rhexia Virginica*, Linn.), the New England representative of the Asiatic family of plants called *melastomaceæ*, of which only 8 species are found in the United States. The flowers, in common with those of the family, are conspicuous and showy, with bright rosy purple petals, and render the meadows unusually gay when enamelled with patches of this lovely plant, entitling it to the common name of the meadow beauty.
